In $L_2(-\infty, +\infty)$ let $\hat H_2$ denote the subspace of functions which vanish to the left of zero and let H_2 denote the Fourier transform of $\hat H_2$. The subspace H_2 is characterized by the Paley-Wiener Theorem and consists of the vertical limits a.e. of functions regular in the upper half-plane which are of uniformly bounded L_2 norm along all lines parallel to the real axis. A subspace $\hat R$ of $\hat H_2$ is right translation-invariant, or briefly, an $\hat R$-space, if along with every function $\hat h(x)$ it also contains all functions $\hat h(x-\tau)$, $\tau>0$, and the Fourier transform of an $\hat R$-space is an R-space in H_2. Similarly, a subspace $\hat L$ of $\hat H_2$ is left translation-invariant, or an $\hat L$-space, if along with every function $\hat h(x)$ it also contains the projections onto $\hat H_2$ of all functions $\hat h(x+\tau)$, $\tau>0$, and the Fourier transform of an $\hat L$-space is an L-space in H_2. $\hat L$- and $\hat R$-spaces are orthogonal complements of one another in $\hat H_2$ and hence the same is true of L- and R-subspaces of H_2. The basic theorem in this context reads as follows: Every R-subspace of H_2 is of the form $G \cdot H_2$, where G is an inner function in H_2, i.e., the vertical limit a.e. of a regular function G in the upper half-plane which satisfies $|G(\lambda)| \leqq 1$ for $\operatorname{Im}\lambda > 0$ [see, e.g., Hoffman, *Banach spaces of analytic functions*, Prentice-Hall, Englewood Cliffs, N.J., 1962; MR **24** #A2844]. If $\hat R$ is the $\hat R$-subspace of $\hat H_2$ whose Fourier transform is R and $\hat L = \hat H_2 \ominus \hat R$, then G is called the characteristic function of $\hat L$.

Now write T for the operator $T : \hat H_2 \to \hat H_2$ given by $\hat h(x) \to \hat h(x+1)$ followed by projection back onto $\hat H_2$. The $\hat L$-subspaces are all invariant under T, and for any such space $T|\hat L$ is a well-defined contraction on $\hat L$. A central problem is to relate the properties of $T|\hat L$ with those of the characteristic function G of $\hat L$. In an earlier paper [J. Math. Anal. Appl. **4** (1962), 276–296; MR **27** #588] the author determined the non-zero spectrum of $T|\hat L$ lying in the open disc; here the problem of the invertibility of $T|\hat L$ is solved. Main results: (1) A necessary and sufficient condition that $T|\hat L$ be invertible is that there exist $\gamma, \delta > 0$ such that $|G(\lambda)| \geqq \delta$ for $\operatorname{Im}\lambda \geqq \gamma$; (2) in this event we have

$$\|(T|\hat L)^{-1}\| \leqq \left[1 + \frac{e^{2\gamma}}{\delta^2(1-e^{-2\gamma})^2}\right]^{1/2}.$$

Benedek, A. 5104

Spaces of differentiable functions and distributions, with mixed norm.

Rev. Un. Mat. Argentina **22**, 3–21 (1964).

Spaces L_u^p $(0<u)$ of tempered distributions with mixed norm are introduced which are related to spaces H_u^p of Sobolev. Among the various results which are obtained by the author we mention an interpolation theorem for the family of spaces L_u^p; under certain hypotheses, which are too involved to repeat here, it is shown that the elements of L_u^p are equal almost everywhere to continuous functions, and a stronger result about the Hölder continuity of the functions belonging to L_u^p $(0 \leq u \leq 1)$ is given.

Constantinesco, F. [Constantinescu, F.] 5105

Sur la valeur d'une distribution dans un point.

Studia Math. **24** (1964), 7–12.

By the theory of values of distributions as developed by Łojasiewicz [same Studia **16** (1957), 1–36; MR **19**, 433], a distribution f has the value 0 at the point $x=0$ if and only if there exist an integer $k \geqq 0$, a neighborhood N of 0, and a continuous function Φ such that $f=D^k\Phi$ on N and $\Phi(x)=o(x^k)$ as $x \to 0$. The author purports to show that the latter condition is equivalent to the condition $[0, x_1, \cdots, x_k] \to 0$ as $(x_1, \cdots, x_k) \to 0$, where $[0, x_1, \cdots, x_k]$ denotes the divided difference of Φ with base points $0, x_1, \cdots, x_k$. Counterexample: $\Phi(x)=x^{k+1} \sin 1/x$, $k \geqq 2$.

On a test for the existence of wave operators. (Russian)

Dokl. Akad. Nauk SSSR **147** (1962), 1008–1009.

The following theorem is stated. If $\varphi(z)$ is a permissible function for the self-adjoint operators H_1 and H_2 and if $\hat{H}_k=\varphi(H_k)$ and $U_k=(\hat{H}_k-iI)(\hat{H}_k+iI)^{-1}$, $\hat{U}_l=(\hat{H}_l-iI)\times(\hat{H}_l+iI)^{-1}$ $(k, l=1, 2)$, where $(\hat{H}_2+iI)^{-1}-(\hat{H}_1+iI)^{-1}$ are nuclear operators, then there exist the following strong limits:

$$W_{\pm}(H_2, H_1) = \lim_{t \to \pm\infty} \exp(iH_2t)\exp(-iH_1t)P_1,$$

$$W_{\pm}(U_2, U_1) = \lim_{n \to \pm\infty} U_2{}^n U_1{}^{-n} P_1,$$

satisfying the relations:

$$W_{\pm}(H_k, H_l) = W_{\pm}(\hat{H}_k, \hat{H}_l) = W_{\pm}(\hat{U}_k, \hat{U}_l) = W_{\pm}(U_k, U_l).$$

Kurepa, Svetozar 5108

On a triangular form of a family of commuting operators. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **18** (1963), 39–42.

In this note the author proves the following two theorems. Theorem 1: Let X be a complex vector space, let F be a family of commuting linear operators defined on X with ranges in X, and suppose that for any A in F there exists a polynomial $p \neq 0$ such that $p(A)=0$. (The polynomial p may depend on A.) If X is finite-dimensional or if F is a finite family, then there exists an algebraic basic set which depends on F only and such that the matrix of A in this basic set is upper triangular for any A in F.

Theorem 2: If X is a complex Hilbert space, if F is a finite family of commuting and continuous linear operators on X into X such that for any A in F there exists an analytic function $f \neq 0$ such that $f(A)=0$, then an orthonormal basic set can be found such that the matrix of A in this basic set is upper triangular for any A in F.

These theorems generalize the well-known theorems that any square matrix of finite order is similar to an upper triangular matrix and any family of commuting normal matrices is similar to a family of diagonal matrices.

Marek, Ivo 5109

A note on K-positive operators.

Comment. Math. Univ. Carolinae **4** (1963), 137–146.

This is a continuation of an earlier paper by the same author [same Comment. **3** (1962), no. 1, 20–30; MR **26** #1763]. The following notation is used: Y is a real Banach space, X is the complex Banach space of couples from Y, defined in a natural way, K is a cone in Y such that the closed linear span of K is Y, T is a bounded linear operator in Y such that $T(K) \subset K$. Spectral properties of T refer to the natural extension of T to become an operator in X. It is further assumed that T is strongly u_0-bounded. This means that there exists a nonzero element u_0 in K such that the following conditions are satisfied: (1) For some positive numbers α, β and some positive integer p, $\alpha u_0 - T^p x \in K$ and $T^p x - \beta u_0 \in K$ for each nonzero x in K; (2) to each x in Y correspond a positive integer p and a real number γ (depending on x) such that $u_0 - \gamma T^p x \in K$. Finally, it is assumed that for some analytic function f of class $\mathfrak{A}_\infty(T)$ (locally analytic on $\sigma(T)$ and at ∞) the operator $f(T)=U+V$ is a Radon-Nikol'skiĭ operator such that $|f(\lambda)| > r_e(V)$ if $|\lambda| = r_e(T)$. (Here U is to be compact and $r_e(V) < r_e(f(T))$.) It is then asserted that T has a simple, positive eigenvalue μ_0 such that $|\lambda| < \mu_0$ if $\lambda \in \sigma(T)$ but $\lambda \neq \mu_0$. There is a corresponding eigenvector x_0 in K. This eigenvalue is a simple pole of the resolvent. Moreover, μ_0 is a simple eigenvalue of the conjugate operator T', with an eigenvector x_0' such that $x_0'(x) > 0$ if x is a nonzero element of K. Finally, it is asserted that the spectral projection of X corresponding to μ_0 is strongly u_0-bounded. This is said to be very important for the construction of μ_0 and x_0 by the Kellogg iterative process [see the author, Czechoslovak Math. J. **12** (87) (1962), 536–554; MR **26** #6787].

Berens, Hubert; Butzer, P. L. 5110

Approximation theorems for semi-group operators in intermediate spaces.

Bull. Amer. Math. Soc. **70** (1964), 689–692.

Let $\{T_t : t \geqq 0\}$ be a holomorphic semi-group of class (C_0) with the infinitesimal generator A in a real or complex Banach space so that, for every $t>0$, $T_tX \subseteq D(A)$, the domain of A, and $\|AT_t\| \leqq M_0 t^{-1}$ as $t \downarrow 0$. Then $\|T_t f - f\| = O(\phi(1/t))$ (as $t \downarrow 0$) implies

$$\|AT_t f\| \leqq M_1 + M_2 t^{-1}\phi(1/t) + M_3 \int_1^{1/t} \phi(u)\,du \qquad (0 < t \leqq 1),$$

where $\phi(u)$ is a positive non-increasing function in $[1, \infty)$ and M_i $(i=0, 1, 2, 3)$ are constants. In particular, under the same hypothesis as above, $\|T_t f - f\| = O(t^\alpha)$ $(0<\alpha<1;$ $t \downarrow 0)$ if and only if $\|AT_t f\| = O(t^{\alpha-1})$ $(t \downarrow 0)$.

Arnautov, V. I. 5111

On the theory of topological rings. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 12–15.

A topological ring is an associative ring which is at the same time a Hausdorff space in which the ring operations are continuous. A two-sided ideal I (not necessarily closed) is called topologically nilpotent if for any neighbourhood V of zero there exists an integer n such that $I^n \subset V$. For a topological ring R, $\mathfrak{N}(R)$ designates the closure of the sum of all nilpotent ideals of R, and for any ordinal α, $\mathfrak{N}_\alpha(R)$ is defined as follows: $\mathfrak{N}_0(R)=0$; if $\beta=\alpha+1$, then $\mathfrak{N}_\beta(R)$ is the inverse image in R of $\mathfrak{N}[R/\mathfrak{N}_\alpha(R)]$; if β is a limit ordinal, then $\mathfrak{N}_\beta(R)$ is the closure of $\sum_{\alpha<\beta} \mathfrak{N}_\alpha(R)$. There exists an ordinal τ such that $\mathfrak{N}_\tau(R) = \mathfrak{N}_{\tau+1}(R)$, and $L(R) = \mathfrak{N}_\tau(R)$ is called a topological radical of Baire. A topological ring R is called an L-radical [L-semi-simple] ring provided $L(R) = R$ [$L(R) = 0$]. The author states that he has proved that $L(R)$ is the intersection of all closed ideals $N \subset R$ such that in R/N there are no non-zero topological nilpotent ideals, and that for any ideal $I \subset R$, $L(I) \subseteq I \cap L(R)$ (it is not mentioned whether or not these results have been published). The author gives an example of an ideal $I \subset R$ such that $L(I) = 0 \subset I \cap L(R) = I$ (this may be also given as an example in which $L(I) = I \cap L(R)$). He also gives an example of rings $\hat{R}$, R', R'' such that $R'+R''$ is a dense subring of $\hat{R}$ and $L(R'+R'') = 0 \subset R'+R'' \cap L(\hat{R}) = R'$, and an example of a commutative L-radical ring with unit element.

W. Żelazko (Warsaw)

Bauer, Heinz 5112

Darstellung von Bilinearformen auf Funktionenalgebren durch Integrale.

Math. Z. **85** (1964), 107–115.

Let X be a locally compact space, and let A be a separating subalgebra of continuous real functions which vanish at infinity. Let $\langle\ ,\ \rangle$ be a bilinear form on A with the properties $\langle f, g\rangle = \langle g, f\rangle$, $\langle f, f\rangle \geqq 0$, $\langle f, gh\rangle = \langle gf, h\rangle$, and $\langle fg, fg\rangle \leqq M_f\|g\|^2$, where M_f depends only on f. The author deduces from this that there exists a Radon measure m on X such that $A \subset L^2(m)$ and

$$\langle f, gh\rangle = \int f(x)g(x)h(x)m(dx)$$

for each triple f, g, h selected from A.

Brown, Arlen; Pearcy, Carl 5113

Structure theorem for commutators of operators.

Bull. Amer. Math. Soc. **70** (1964), 779–780.

In the present paper, the authors announce an interesting result concerning commutators of operators. Here some indication of its proof is given. Details will appear elsewhere.

Let $\mathfrak{H}$ be a separable Hilbert space, and A a bounded operator on $\mathfrak{H}$; then A is a commutator if there exist bounded operators B and C on $\mathfrak{H}$ such that $A = BC - CB$. Wintner [Phys. Rev. (2) **71** (1947), 738–739; MR **8**, 580] and Wielandt [Math. Ann. **121** (1949), 21; MR **11**, 38] showed that no nonzero scalar multiple of the identity operator on $\mathfrak{H}$ is a commutator. Halmos [*Lectures on modern mathematics*, Vol. 1, pp. 1–22, Wiley, New York, 1963] generalized it as follows: No operator of the form $\lambda 1 + C$ is a commutator, where $\lambda \neq 0$ and C is a compact operator. Here the authors state the converse theorem as follows. An operator A on a separable Hilbert space $\mathfrak{H}$ is a commutator if and only if A is not of the form $\lambda 1 + C$, where $\lambda \neq 0$ and C is a compact operator.

Moreover, they state that results analogous with the above hold for an arbitrary infinite-dimensional Hilbert space. The reviewer thinks that the following problem is also interesting: Can we generalize the above theorem to a von Neumann factor of type II_∞ or III?

S. Sakai (Philadelphia, Pa.)

Gardner, L. Terrell 5114

A note on isomorphisms of C^*-algebras.

Bull. Amer. Math. Soc. **70** (1964), 788–791.

In the present paper, the author states two interesting results concerning isomorphisms of C^*-algebras. Their proofs are sketched. Full details will appear elsewhere. Definition: The atomic representation α of a C^*-algebra $\mathfrak{A}$ is the direct sum $\bigoplus_{\rho\in\mathscr{E}} \phi_\rho$ of the representations ϕ_ρ due to pure states ρ of $\mathfrak{A}$, where $\mathscr{E}$ is the set of all pure states of $\mathfrak{A}$.

Theorem 2: Let ψ be an algebraic isomorphism (not necessarily $*$-preserving) of the C^*-algebra $\mathfrak{A}$ onto the C^*-algebra $\mathfrak{B}$, and let α [β] be the atomic representation of $\mathfrak{A}$ [$\mathfrak{B}$] on the Hilbert space $\mathfrak{H}$ [$\mathfrak{K}$]. Then $\beta\psi\alpha^{-1}$ can be extended to an isomorphism of $L(\mathfrak{H})$ onto $L(\mathfrak{K})$ of the form $A \to SAS^{-1}$ for some S in $L(\mathfrak{H}, \mathfrak{K})$, where $L(\mathfrak{H})$ [$L(\mathfrak{K})$] is the algebra of all bounded operators on $\mathfrak{H}$ [$\mathfrak{K}$] and $L(\mathfrak{H}, \mathfrak{K})$ is the space of all bounded operators of $\mathfrak{H}$ into $\mathfrak{K}$.

This theorem implies that isomorphisms between C^*-algebras are in a certain sense "spatial" in nature. By means of Theorem 2, the author gives an affirmative solution to a fundamental problem in the theory of C^*-algebras [cf. the reviewer, "The theory of W^*-algebras", p. 1.53, Problem (i) (mimeographed notes), Yale Univ., New Haven, Conn., 1962] as follows. Theorem 3: If two C^*-algebras are algebraically isomorphic, then they are $*$-isomorphic.

Johnson, B. E. 5115

Centralisers on certain topological algebras.

J. London Math. Soc. **39** (1964), 603–614.

The author applies the results of his previous paper [Proc. London Math. Soc. (3) **14** (1964), 299–320; MR **28** #2450] to various topological algebras: $\mathscr{C}_0(\mathscr{T})$, $L_1(G)$, $\mathscr{C}_{00}(G)$, and $\mathscr{D}L_1$.

J. G. Wendel (Ann Arbor, Mich.)

Ingelstam, Lars 5116

Non-associative normed algebras and Hurwitz' problem.
Ark. Mat. **5**, 231–238 (1964).

Let A be an algebra (non-associative) over the real or complex field with an identity e. It is assumed that A is normed as a linear space, where the norm satisfies one or more of the following conditions. (1) A positive-definite inner product (x, y) is defined on A, where $\|x\|^2=(x, x)$; (2) $\|xy\|=\|x\|\,\|y\|$ for all x, y; (3) $\|e\|=1$ and $\|xy\|\leq\|x\|\,\|y\|$ for all x, y. In case (1) and (3) are satisfied, A is called a pre-Hilbert algebra with an identity. In case (2) is satisfied, A is called an absolute-valued algebra. The classical result of A. Hurwitz referred to in the title is that if A is finite-dimensional and (1) and (2) hold, then A is isomorphic to the real numbers R, the complex numbers C, the quaternions Q, or the Cayley numbers D.

It is shown that (a) if A is a power associative real [complex] absolute-valued algebra with identity, then A is isomorphic to R, C, Q or D (isomorphic to C), and (b) if A is a real [complex] alternative pre-Hilbert algebra with identity, then the same conclusion holds. Various related algebras are studied. In particular, it is shown that in (b) "alternative" cannot be replaced by "power associative". *B. Yood* (Eugene, Ore.)

Maltese, George 5117

Convex ideals and positive multiplicative forms in partially ordered algebras.
Math. Scand. **9** (1961), 372–382.

Un "coin" B^+ d'une algèbre sur $\mathbf{R}$ en est une partie stable pour l'addition, la multiplication par un réel positif et l'élévation au carré. La donnée d'un coin permet de définir un préordre partiel ($f\geq g \Leftrightarrow f-g\in B^+$). Une forme est positive si elle prend des valeurs réelles positives sur le coin. Un idéal I est convexe si $f\in I$, $g\in I$, $f\leq h\leq g$ implique que $h\in I$. Théorème: La condition nécessaire et suffisante pour qu'un idéal d'une algèbre de Banach réelle, commutative, munie d'un coin, soit le noyau d'une forme linéaire, multiplicative, positive et continue est qu'il soit convexe, régulier et maximal. Appliqué à $L^1(G, \mathbf{R})$ cela conduit à un résultat de Aubert: le seul idéal maximal régulier convexe de $L^1(G, \mathbf{R})$ est le noyau de la mesure de Haar [Aubert, Math. Scand. **6** (1958), 181–188; MR **21** #2918]. Théorème: Si V est une algèbre ordonnée sur $\mathbf{R}$ (multiplication notée $*$), dont V^+ est le cône positif stable pour la multiplication, contenant un élément 1 tel que $\forall f\in V$, $\exists\lambda_f\in\mathbf{R}$, $-\lambda_f f\leq 1\leq\lambda_f f$, et tel que $\forall f\in V^+$, $f\neq 0$, $\exists\alpha_f\in\mathbf{R}^+$ tel que $1*f\geq\alpha_f 1$, il existe une forme linéaire non nulle sur V qui soit positive et multiplicative. *A. Revuz* (Poitiers)

Naimark, M. A. 5118

Commutative operator algebras in the space Π_1. (Russian)
Dokl. Akad. Nauk SSSR **156** (1964), 734–737.

Let Π_1 denote a complex linear space with an indefinite scalar product (ξ, η) (see, for the definition and first properties of this concept, I. S. Iohvidov and M. G. Kreĭn [Trudy Moskov. Mat. Obšč. **5** (1956), 367–432; MR **18**, 320]). The present paper classifies (without proofs) all commutative self-adjoint algebras R of bounded linear operators on Π_1. The result is quite complicated. One considers various subcases depending on the properties of the family of all one-dimensional non-negative subspaces of Π_1 invariant under R. *J. M. G. Fell* (Seattle, Wash.)

Rudin, Walter; Schneider, Hans 5119

Idempotents in group rings.
Duke Math. J. **31** (1964), 585–602.

It is known that every idempotent in $L^1(G)$ for an abelian discrete group G has a finite support group. The authors show that this is also true for group rings of L^1-type over commutative Banach algebras. A purely algebraic analogue of this theorem and related discussions are given. *I. G. Amemiya* (Sapporo)

Taylor, Joseph L. 5120

The Tomita decomposition of rings of operators.
Trans. Amer. Math. Soc. **113** (1964), 30–39.

Let R be a separable C^*-algebra of bounded operators on a separable Hilbert space H and ξ_0 a vector in H which is cyclic with respect to R; then the positive functional $F(A)=(A\xi_0, \xi_0)$ for $A\in R$ may be written as an integral on a compact space M, i.e., $F(A)=\int_M f_m(A)\,d\mu(m)$, where μ is a positive regular Borel measure and the functionals f_m are pure for $m\in M-M_0$ and $\mu(M_0)=0$. Moreover, this decomposition induces a representation of R as a direct integral of ring R_m of operators on Hilbert spaces H_m and for almost all m, R_m is irreducible. This has been shown by many authors [cf. Segal, Mem. Amer. Math. Soc. No. 9 (1951); MR **13**, 472; Godement, Ann. of Math. (2) **53** (1951), 68–124; MR **12**, 421; Naimark, *Normed rings* (Russian), GITTL, Moscow, 1956; MR **19**, 870] as a refined form of Mautner's theorem [Ann. of Math. (2) **51** (1950), 1–25; MR **11**, 324] obtained by the help of the von Neumann reduction theory [ibid. (2) **50** (1949), 401–485; MR **10**, 548].

Tomita [Math. J. Okayama Univ. **3** (1954), 147–173; MR **15**, 968] studied the problem of extending this type of decomposition to C^*-algebras on an arbitrary Hilbert space, using neat techniques, and Naimark gave the elegant introduction of Tomita's theory in his book [loc. cit.].

However, unfortunately, certain parts of Tomita's development require a special measure-theoretic result which is not valid in general, as has been noticed by several mathematicians (Hewitt, in his review of Naimark's book, op. cit.; Lorch, in his review of the English transl. [Noordhoff, Groningen, 1959; MR **22** #1824] in Bull. Amer. Math. Soc. **69** (1963), 193–195). Consequently, it has been an interesting question whether or not this measure-theoretic difficulty could be circumvented.

In the present paper, the author gives a negative solution to this question, namely, he constructs a C^*-algebra where the Tomita decomposition fails to hold (Theorem 3.3). (The proofs of Lemmas 3.4 (b) and 3.5 are incomplete, and those lemmas are likely incorrect. However, by changing the discussions, we can easily see that Theorem 3.3 is still right. In his communications with the reviewer, the author wants to replace them by the following statements. Lemma 3.4 (b): If R_1 is the ring of operators (not the closed ring) generated by $C\cup T$, then $A\in R_1\Rightarrow AS\subset S$. Lemma 3.5: For each $A\in R_1$ and $m\in M$, there is a unique operator $A_m\in B(H)$ such that $(A\alpha)(g, m)=(A_m\alpha_m)(g)$, where $\alpha_m\in H$ and is the function determined by $\alpha_m(g)=\alpha(m, g)$ for $\alpha\in S$; finally, the correspondence

$A \to A_m$ may be extended to a symmetric, norm-decreasing representation of R onto a ring $R_m \subset B(H)$.}

Moreover, he shows that the Tomita decomposition holds if R is a W^*-algebra containing its commutant (Theorem 2.3).

Thus, it is impossible to extend Mautner's theorem to the general non-separable case in the above form. But this does not necessarily imply the impossibility of Mautner's theorem in the non-separable case; in fact, by the theorem of Bishop and de Leeuw [Ann. Inst. Fourier (Grenoble) **9** (1959), 305–331; MR **22** #4945], we may have a weaker form of Mautner's theorem in the non-separable case [cf. Loomis, Amer. J. Math. **84** (1962), 509–526; MR **26** #2575]. *S. Sakai* (Philadelphia, Pa.)

Wulfsohn, Aubrey 5121

Produit tensoriel de C^*-algèbres.

Bull. Sci. Math. (2) **87** (1963), *1ière partie*, 13–27.

The author begins by defining the C^*-tensor product $A \overset{*}{\otimes} B$ of two C^*-algebras A and B. For this he first considers A and B as concrete algebras of operators in Hilbert spaces H and K, respectively; he identifies the algebraic tensor product $A \otimes B$ in the natural way with a $*$-algebra of operators on the tensor product Hilbert space $H \otimes K$, and defines $A \overset{*}{\otimes} B$ as the completion of $A \otimes B$. Then he shows that $A \overset{*}{\otimes} B$ is independent (in the obvious sense) of the particular concrete realizations of A and of B, and so is defined for any two abstract C^*-algebras A and B.

Next he proves that $A \overset{*}{\otimes} B$ is of Type I if and only if A and B are of Type I. Finally, he shows that if either A and B is of Type I, then the dual space $(A \overset{*}{\otimes} B)^\wedge$ of $A \overset{*}{\otimes} B$ can be identified both setwise and topologically with $\hat{A} \times \hat{B}$. *J. Yamazaki, Saburo 5123

Normed ring and unconditional bases in Banach space.

Sci. Papers College Gen. Ed. Univ. Tokyo **14** (1964), 1–10.

An unconditional basis for a Banach space E is a sequence $e_1, e_2, \cdots$ of elements for which a sequence $f_1, f_2, \cdots$ exists in E' such that $\sum_{i=1}^\infty f_i(x)e_i$ converges unconditionally to x for each x in E. If $e_1, e_2, \cdots$ is such a basis, then one can make the space (m) act in E as follows. For $a = (a_1, a_2, \cdots) \in (m)$ let $A_a(\sum \lambda_i e_i) = \sum \lambda_i a_i e_i$. This gives rise to a Banach algebra M of operators in E. The following converse is one of several theorems proved involving these ideas. Suppose there is an algebra M of operators isomorphic $(a \to A_a)$ to (m), such that when $a = (0, 0, \cdots, 0, 1, 0, \cdots)$, the range of A_a is one-dimensional. Suppose that the linear envelope of these ranges is dense. Then E has an unconditional basis.

Errata: Remark on "Measures orthogonal to a Dirichlet algebra".

Duke Math. J. **31** (1964), 717.

The authors show that the lemma in § 5 of an earlier paper [same J. **30** (1963), 661–666; MR **27** #6150] can be proved without appeal to Proposition 6.

Minty, George J. 5125a

On the monotonicity of the gradient of a convex function.

Pacific J. Math. **14** (1964), 243–247.

Minty, George J. 5125b

On the solvability of nonlinear functional equations of 'monotonic' type.

Pacific J. Math. **14** (1964), 249–255.

Let X be a Banach space, Y its conjugate. A set E in $X \times Y$ is monotone if $\mathrm{Re}\langle x_1 - x_2, y_1 - y_2\rangle \geq 0$ for all (x_1, y_1), (x_2, y_2) in E. A nonlinear operator $F: X \to Y$ is monotone provided its graph in $X \times Y$ is monotone, i.e., $\mathrm{Re}\langle x_1 - x_2, F(x_1) - F(x_2)\rangle \geq 0$ for all x_1, x_2 in X.

In a recent paper [Duke Math. J. **29** (1962), 341–346; MR **29** #6319] the author exploited properties of monotone operators F to prove the existence and uniqueness of solutions of equations $(I + F)x = y$ in Hilbert spaces. The interest in such monotone operators is in their relationship to the (Fréchet) derivative of convex real-valued functions, and their generalization to the nonlinear case of the "dissipative" linear operators ($\mathrm{Re}\langle x, F(x)\rangle \geq 0$ [C. L. Dolph, Bull. Amer. Math. Soc. **67** (1961), 1–69; MR **25** #5612]) of mathematical physics.

Recall that "the derivative of a convex function of one real variable is monotone nondecreasing". The first paper generalizes this to a real-valued convex function φ defined on a real topological vector space X. But the requirement of differentiability is replaced by using the "generalized gradient" of φ, viz., a map assigning to x_0 all those y_0 in the conjugate space Y such that $r = \varphi(x_0) + \langle x - x_0, y_0\rangle$ is the equation of a hyperplane of support of the points above the graph of φ in $X + R$. Specifically, the graph (in $X \times Y$) of the generalized gradient of φ is a monotonic set. It is a maximal monotonic set if φ is continuous. (The paper has more general statements.) As a consequence, in Hilbert space, "if φ is, in addition, Fréchet differentiable, then the equation $x + \varphi'(x) = u$ is always solvable for x, and the solution depends continuously on u".

The second paper generalizes the "intermediate value theorem" to reflexive Banach spaces X with smooth unit ball. Notation: Y is the conjugate space; P is the projection of $X \times Y$ onto Y; and $K[S]$ is the convex hull of S. Theorem: If $E \subset X \times Y$ is a maximal monotonic set, then a sufficient condition that $\theta \in P(E)$ is that there exist a set $A \subset E$ with the properties (i) $\theta \in$ interior $K[P(A)]$, and (ii) $\{\mathrm{Re}\langle x, y\rangle : (x, y) \in A\}$ is bounded above. An application is given in Hilbert space H for a function $f: H \to H$ whose Fréchet derivative exists everywhere and is a dissipative linear operator, to conclude $f(x) = \theta$ has a solution. Several generalizing remarks are given.

R. H. Moore (Milwaukee, Wis.)

Amerio, Luigi 5126

Su un teorema di minimax per le equazioni differenziali astratte.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 409–416.

On considère l'équation opérationnelle

$$(\mathrm{E})\quad \int_J \{(x'(t), h'(t))_Y - (A(t)x(t), h(t))_X + (B(t)x'(t), h(t))_X - (f(t), h(t))_Y\}\, dt = 0,$$

$J = (-\infty, +\infty)$, où X et Y sont deux espaces de Hilbert, $X \subset Y$, l'immersion étant continue, X est dense dans Y, $A(t) \in \mathfrak{L}(X, X)$ et $B(t) \in \mathfrak{L}(Y, X)$ étant supposées continues. Les dérivées sont considérées au sens généralisé et l'on admet $x(t), h(t) \in L^2(\Delta, X), x'(t), h'(t), f(t) \in L^2(\Delta, Y)$, quel que soit l'ensemble compact $\Delta \subset J$. La fonction arbitraire $h(t)$ est à support compact. Soit $\Delta_p = \{t : t \in J,\ |t| \leq p + \frac{1}{2},\ p = 0, 1, 2, \cdots\}$. Par W_p on désigne l'espace de Hilbert des fonctions $g(t)$, $t \in \Delta_p$, telles que $g(t) \in L^2(\Delta_p, X)$, $g'(t) \in L^2(\Delta_p, Y)$. Soit $x(t)$ W_0-bornée, c'est-à-dire, telle que $\sup_{t \in J} \|z(t)\|_{W_0} < +\infty$. Posons $\varphi(z\,;\tau) = \sup_{t \in J} \|z(t+\tau) - z(t)\|_{W_0}$. Par Λ_z on désignera l'ensemble $\{x(t)\}$ des fonctions W_0-bornées, telles que $\varphi(x\,;\tau) \leq \varphi(z\,;\tau)$ pour tout $\tau \in J$ et par $\Lambda_{z,Q,f}$ l'ensemble des solutions de l'équation (E), appartenant à Λ_z. Enfin, $\Lambda_{z,Q}$ désignera l'ensemble des solutions non-nulles de l'équation homogène associée à (E). En admettant l'existence d'une fonction W_0-bornée $z(t)$ telle que $\Lambda_{z,Q,f}$ ne soit pas vide et que $\inf_{t \in J} \|u(t)\|_{W_0} > 0$ pour tout $u(t) \in \Lambda_{z,Q}$, on démontre l'existence d'une fonction unique $\hat{x}(t) \in \Lambda_{z,Q,f}$, pour laquelle $\inf_{\Lambda_{z,Q,f}} \sup_{t \in J} \|x(t)\|_{W_0}$ est atteint. Sous diverses hypothèses on établit des propriétés de la fonction qui réalise le minimax (par exemple, la continuité uniforme, la presque-périodicité). *C. Corduneanu* (Iaşi)

Campanato, S. 5127

Proprietà di una famiglia di spazi funzionali.

Ann. Scuola Norm. Sup. Pisa (3) 18 (1964), 137–160.

The author defines the space $\mathscr{L}_k^{(q,\lambda)}(\Omega)$ to consist of all $u \in \mathscr{L}_q(\Omega)$ for which the seminorm

$$|||u|||_{k,q,\lambda} = \sup\left[\rho^{-\lambda} \inf \int_{\Omega(x_0,\rho)} |u(x) - P(x)|^q\, dx\right]^{1/q} < +\infty,$$

the sup being for all $x_0 \in \bar{\Omega}$ and $0 < \rho \leq d(\Omega) = \operatorname{diam} \Omega$ and the inf being for all polynomials P of degree $\leq k$. The norm is defined by $\|u\|_{k,q,\lambda} = \|u\|_{L_q} + |||u|||_{k,q,\lambda}$. The domain Ω is said to satisfy the condition (I) if and only if there exists an $A > 0$ such that $\operatorname{meas}[\Omega \cap B(x_0, \rho)] \geq A\rho^n$ for every x_0 in $\bar{\Omega}$ and each ρ, $0 \leq \rho \leq d(\Omega)$, A being independent of x_0. The principal theorem of the paper is that if $u \in \mathscr{L}_k^{(q,\lambda)}(\Omega)$ with $n + kq < \lambda \leq n + (k+1)q$, $q \geq 1$, and if Ω satisfies condition (I), then $u \in C_\alpha^k(\bar{\Omega})$ with $\alpha = (\lambda - n - kq)/q$; if $\lambda > n + (k+1)q$, then u is a polynomial of degree $\leq k$. *C. B. Morrey, Jr.* (Berkeley, Calif.)

Fedorjuk, M. V. 5128

The asymptotic behavior of the discrete spectrum of the operator $-w''(x) + \lambda^2 p(x) w(x)$. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 540–542.

Consider the eigenvalue problem $w''(x) - \lambda^2 p(x) w(x) = 0$, $w(\pm\infty) = 0$. Suppose $p(z)$ (z a complex variable) is a polynomial with real coefficients, $p(x)$ has precisely two zeros $x_1 < x_2$ which are simple, and $p(\pm\infty) = +\infty$. Then for $n \to \infty$ we have the asymptotic expansion

$$\lambda_n \int_C [p(z)]^{1/2}\, dz \sim 2\pi n i + \pi i + \sum_{k=1}^{\infty} \lambda_n^{-k} \int_C \alpha_k(z)\, dz,$$

where $0 < \lambda_1 < \lambda_2 < \cdots$ are the eigenvalues of the problem and C is a certain contour encompassing the segment $[x_1, x_2]$ but not containing other zeros of p. Explicit formulas are given for the α_k in terms of p and its derivatives. Conditions are given under which the asymptotic expansion holds for more general polynomials, and also for entire functions p. In the case that p is an entire function, the expansion holds up to $O(\lambda_n^{-2})$.

On the equivalence of differential operators in the space of functions analytic in a circle. (Russian)

Uspehi Mat. Nauk **19** (1964), *no.* 5 (119), 143–147.

The structure problem is solved for a general class of linear differential operators in the space of functions analytic in a disk. The operators considered are of the form $D^s + \sum_{i=1}^{s} P_i(z) D^{s-i}$, where $D = d/dz$ and the coefficients are analytic in the disk. Any such operator is similar to D^s.

L. de Branges (Lafayette, Ind.)

Hildebrandt, S. 5130

Einige konstruktive Methoden bei Randwertaufgaben für lineare partielle Differentialgleichungssysteme und in der Theorie harmonischer Differentialformen. I.

J. Reine Angew. Math. **213** (1963/64), 66–88.

In this paper the author defines certain iteration schemes which he proves, under appropriate hypotheses, converge to a solution of the Dirichlet problem for a strongly elliptic system of order $2m$ in divergence form. These methods include the alternating method of Schwarz, the method of balayage of Poincaré, and the Ritz method. Let J be the totality of positive integers and let $J' = J$ or $J' = \{1, \cdots, k\}$ for some $k > 1$. The author considers regular partitions of J into sets J_m for $m \in J'$; the sets J_m are disjoint, their union is J, and the "regularity" requires additional restrictions. If $J' = \{1, \cdots, k\}$, one example of such a regular partition is obtained by taking $J_m = \{m, m+k, m+2k, \cdots\}$. Each of the author's methods depends on a theorem concerning the limit of a sequence of projections in a Hilbert space $\mathfrak{H}$ of which we quote two. Suppose P_m denotes the projection of $\mathfrak{H}$ onto $\mathfrak{A}_m$ ($m \in J'$), where $\bigcap \mathfrak{A}_m = \{0\}$; define the operators $L_i = P_m$ if $i \in J_m$, and $A_p = L_p \cdots L_1$. Then (1) If $J = \bigcup J_m$ is a regular partition, $x_0 = x$, and $x_i = L_i x_{i-1}$ for each $i \geq 1$, then $x_i \rightharpoonup$ (tends weakly to) 0 as i runs through each J_m; if J' is finite, the whole sequence converges. (2) If $J' = \{1, \cdots, k\}$ and $\mathfrak{A}_1, \cdots, \mathfrak{A}_k$ are such that each element $x = x_1 + \cdots + x_k$ with $x_m \in \mathfrak{H} \ominus \mathfrak{A}_m$ and $\|x_m\| \leq M\|x\|$ (M independent of x) and $J = \bigcup J_m$ is the particular partition above, then the operators A_p tend strongly to 0. The system of equations which is considered is of the form

$$D(y, v) = \int_T \sum_{i,j=1}^{N} \sum_{|\alpha|,|\beta| \leq m} a_{ij}^{\alpha\beta}(t) D^\alpha v^i D^\beta y^j\, dx = l(v),$$

$$v \in W_{20}^m,\ y - g \in W_{20}^m,$$

$W_{20}{}^n$ being the completion of $C_c{}^\infty(T)$ in the Sobolev space of vectors with nth derivatives in L_2. It is assumed that the form $D(x, x) \geqq \|x\|^2$ for $x \in W_{20}{}^n$, in which case we call $\mathfrak{H}_0{}^n$ the set of elements of $W_{20}{}^n$ with inner product $D(x, y)$. Then we let $\mathfrak{C}_m$ be subspaces of $\mathfrak{H}_0{}^n$, and define the operators C_m by the equation $C_m x = x + c_m$, where c_m is the unique element in $\mathfrak{C}_m$ such that $D(x+c_m, v) = l(v)$, $v \in \mathfrak{H}_0{}^n$. We define $B_i = C_m$ for $i \in J_m$, set $y_0 = g$, $y_i = B_i y_{i-1}$, $x_i = y_i - y_0$. Then x_i tends to zero. Several ways of setting up the spaces $\mathfrak{C}_m$ are exhibited.

Kaližanov, U. 5131

Holomorphic solutions of countable systems of differential equations in normed linear spaces. (Russian. Kazak summary)

Izv. Akad. Nauk Kazah. SSR Ser. Fiz.-Mat. Nauk **1963**, *no.* 3, 66–70.

The author gives the results (too complicated to be quoted here) concerning the existence of holomorphic solutions of the countable systems of differential equations

$$\frac{dx_s}{dt} = \varphi_s(t, x_1, x_2, \cdots), \qquad s = 1, 2, \cdots,$$

in normed linear spaces. A similar problem has been considered earlier by K. P. Persidskiĭ [Izv. Akad. Nauk Kazah. SSR Ser. Mat. Meh. **1959**, no. 7 (11), 52–71; ibid. **1961**, no. 9 (13), 11–34]. *B. S. Popov* (Skopje)

Kužel', A. V. 5132

On the spectrum of a regular quasi-differential operator. (Russian)

Dokl. Akad. Nauk SSSR **156** (1964), 731–733.

Suppose that the operator A in $L^2(a, b)$ is defined by a regular quasi-differential operator

$$l(y) = \sum_{k=0}^{n} (-1)^k (p_{n-k} y^{(k)})^{(k)},$$

not necessarily self-adjoint, and the boundary conditions

$$\sum_{k=1}^{2n} a_{jk} y^{[k-1]}(a) + \sum_{k=1}^{2n} b_{jk} y^{[k-1]}(b) = 0, \qquad 1 \leqq j \leqq 2n,$$

where $y^{[k-1]}$ is a quasi-derivative. Suppose that the rank of the matrix $\|a_{jk}\|$ is r_a, and the rank of $\|b_{jk}\|$ is r_b, where $r_a r_b \neq 0$ and $r_a + r_b = 2n$. Set $n_1 = 2n - r_a$, $n_2 = 2n - r_b$, and let $\{u_s(x, \lambda) : 1 \leqq s \leqq n_1\}$ be a set of linearly independent solutions of $l(u) = \lambda u$ satisfying the boundary conditions $\sum_{k=1}^{2n} a_{jk} u_s{}^{[k-1]}(a, \lambda) = 0$, $1 \leqq j \leqq 2n$, and let $\{u_s(x, \lambda) : n_1 < s \leqq 2n\}$ be a set of n_2 linearly independent eigenfunctions satisfying the boundary conditions

$$\sum_{k=1}^{2n} b_{jk} u_s{}^{[k-1]}(b, \lambda) = 0, \qquad 1 \leqq j \leqq 2n.$$

Let $W(\lambda)$ be the Wronskian formed by using the quasi-derivatives of the functions in the set $\{u_s(x, \lambda) : 1 \leqq s \leqq 2n\}$. $W(\lambda)$ is independent of x, and the author announces that the zeros of $W(\lambda)$ are eigenvalues of the operator A. He also announces a partial converse to the effect that the non-real eigenvalues of A are zeros of $W(\lambda)$.

The operator A is called simple in case there is no non-trivial subspace of $L^2(a, b)$ which reduces A to a self-adjoint operator. In case A is simple, necessary and sufficient conditions are given, in terms of its eigenvalues, that the eigenelements of A are dense in $L^2(a, b)$.

A. Devinatz (St. Louis, Mo.)

Lax, Peter D.; Phillips, Ralph S. 5133

Scattering theory.

Bull. Amer. Math. Soc. **70** (1964), 130–142.

In this formulation of quantum scattering theory, the basic concept is a one-parameter group of unitary operators $U(t)$ and a pair of orthogonal closed subspaces D_+ and D_- of the Hilbert space, D_+ invariant under $U(t)$ for $t > 0$ and D_- invariant under $U(t)$ for $t < 0$. The scattering operator is an operator-valued analytic function which is bounded by 1 in the unit disk and which characterizes the situation within unitary equivalence. The Hilbert space considered consists of pairs (Df, g) of a square integrable vector field Df of zero curl and a square integrable function g, both defined in Euclidean 3-space. The operator $U(t)$ propagates the field through time t according to Maxwell's equations. If Ω is a given obstacle (i.e., region) of Euclidean space, the spaces D_+ and D_- consist of all fields which vanish in Ω at all later times and at all earlier times, respectively. It is shown that D_+ and D_- are orthogonal, so that a scattering operator exists. An integral representation of the scattering operator is then derived from the Fourier transformation. The scattering operator is said to determine the obstacle Ω. Special attention is given to star-shaped obstacles and a related compactness property of the scattering operator. Generalizations to Euclidean spaces of higher odd dimensions and to general hyperbolic differential operators are indicated. *L. de Branges* (Lafayette, Ind.)

Zaidman, Samuel 5134

Quasi-periodicità per una equazione operazionale del primo ordine.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 152–157.

Soient V et H deux espaces de Hilbert tels que $V \subset H$, l'immersion étant algébrique et continue. De plus, V est dense dans H. Soit $a(u, v)$ une forme sesquilinéaire continue sur V, telle que $a(u, v) = \overline{a(v, u)}$, $a(u, u) + \lambda|u|_H{}^2 \geqq \alpha|u|_V{}^2$, où $\lambda, \alpha > 0$ sont des constantes. Il existe un opérateur auto-adjoint A, tel que $a(u, v) = (Au, v)_H$. Soient enfin $V^{1-\theta}H^\theta$ les espaces intermédiaires de Lions [Bull. Math. Soc. Sci. Math. Phys. R. P. Roumaine (N.S.) **2** (50) (1958), 419–432; MR **27** #1812]. On a $V \subset V^{1-\theta}H^\theta \subset H$, au sens algébrique et topologique. Le résultat principal établi par l'auteur est un théorème du type Bohr-Neugebauer qui peut s'énoncer: Soit $f(t)$ une fonction presque-périodique sur $J = (-\infty, +\infty)$ à valeurs dans H. Si une solution $u(t)$ de l'équation $u'(t) + Au(t) = f(t)$ est telle que $u(t) \in L^2_{loc}(J, V)$, $u'(t) \in L^2_{loc}(J, H)$, $|u(t)|_H \leqq M$ pour $t \in J$, $M > 0$ étant une constante, alors $u(t)$ est presque-périodique comme fonction de $t \in J$, à valeurs dans $V^{1-\theta}H^\theta$, $0 < \theta \leqq 1$. *C. Corduneanu* (Iaşi)

Seidman, Thomas I. 5135

Linear transformation of a functional integral. II.

Comm. Pure Appl. Math. **17** (1964), 493–508.

Part I appeared in same Comm. **12** (1959), 611–621 [MR

22 #892]; correction, ibid. 16 (1963), 95 [MR 26 #6801]. Consider on R^∞ the countable direct product of real lines R, the product measure μ of the measures μ_1 on R^∞, where

$$\mu_1(E) = \frac{1}{\sqrt{(2\pi)}\sigma}\int_E \exp\{-x^2/2\sigma^2\}\,dx.$$

The real Hilbert space l_2 is imbedded in a natural manner in R^∞, and bounded linear operators on l_2 can be extended linearly to μ-almost all of R^∞ such that the extension of a linear combination of such operators is the corresponding linear combination of the separate extensions. The following main theorem is proved.

Let T be a bounded linear operator on l_2 of the form $T = V(I+A)$, where $I+A$ is nonsingular, A is Hilbert-Schmidt and $VV^* = I$. If the extension of T on R^∞ is also denoted by T, then the inverse image $T^{-1}(E)$ of every μ-measurable set $E \subset R^\infty$ is also μ-measurable, and the measure $\mu_T = \mu \circ T$ on the collection of these inverse images is μ-absolutely continuous. Denote $d\mu_T/d\mu$ by J_T. If f is μ-integrable over R^∞, then $g(x) = f(Tx)J_T(x)$ is also μ-integrable over R^∞, and both integrals are equal.

It is observed by the author that this result is similar to a result proved by I. E. Segal [Trans. Amer. Math. Soc. 88 (1958), 12–41; Theorem 3; MR 21 #1545]. The proof given here is more elementary. *A. C. Zaanen* (Leiden)

Bolonkin, O. O. 5136

The calculus of variations and a functional equation of Bellman, and an interpretation of Lagrange's undetermined multipliers. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 1290–1293.

Author's summary: "In this article a simple inference from Bellman's equation in variational calculus is suggested. An interpretation is given for Lagrange's undetermined multipliers."

GEOMETRY

See also 4766, 4804, 4909, 5172.

Brossard, Roland 5137

Birkhoff's axioms for space geometry.

Amer. Math. Monthly 71 (1964), 593–606.

The author takes up Birkhoff's axioms of plane geometry [Ann. of Math. (2) 33 (1932), 329–345] and modifies them to build up space geometry on the model of Veblen [Trans. Amer. Math. Soc. 5 (1904), 343–384]. The system of axioms is based on coordinate functions. They are intuitively conceived as applications of a long graduated ruler and a protractor. Distance, angular measure and the betweenness relation are defined in terms of coordinate functions. Plane bundles of half-lines and axioms of continuity and similarity are used to develop this otherwise well-known euclidean geometry. The congruence of triangles is defined by similarity with a factor of proportionality K equal to one as was done by Birkhoff. Playfair's axiom of parallelism and Pasch's axiom of order are deduced as theorems.

S. R. Mandan (Kharagpur)

Corsi, Gabriella 5138

Sui sistemi minimi di assiomi atti a definire un piano grafico finito.

Rend. Sem. Mat. Univ. Padova **34** (1964), 160–175.

A. Barlotti [Boll. Un. Mat. Ital. (3) 17 (1962), 394–398; MR 26 #5473] considered minimal complete subsets of six conditions which are necessary and sufficient to determine a graphic plane. The author splits up each of these six conditions into two (thus the condition "there is exactly one line joining two points" is replaced by the two conditions "there is at least [at most] one line joining two points") and proceeds to determine all minimal complete subsets of these twelve conditions. There are 42 such sets.

J. A. Todd (Cambridge, England)

Bereis, Rudolf 5139

★Darstellende Geometrie. I.

Mathematische Lehrbücher und Monographien, I. Abt., Mathematische Lehrbücher, Band XI.

Akademie-Verlag, Berlin, 1964. xvi + 493 *pp.* *DM* 35.00.

Dieses 500 Seiten starke Buch stellt den ersten Band eines auf drei Bände geplanten Werkes dar. Der erste Band benutzt durchweg zugeordnete Normalrisse. Nach Erledigung von Grundaufgaben werden ebenflächige Körper ausführlichst behandelt. Es folgen die Kegelflächen zweiter Ordnung (vorbereitet durch ein Studium der Kegelschnitte), die Zylinder und die Kugel. Verfasser geht sodann zu allgemeinen Rotationsflächen über mit spezieller Berücksichtigung derer von zweiter Ordnung. Ein kurzes Kapitel über den Torus und ein ausführliches über gewisse Durchdringungsprobleme krummer Flächen beschliesst den Band. Im zweiten und dritten Band werden Schraubenflächen, ebene und sphärische Kinematik, kotierte Projektion, Axonometrie und Perspektive behandelt.

Wie man sieht, ein umfassendes und breit angelegtes Werk, solide und verlässlich. Es geht, wie der Verfasser auch hervorhebt, über den Rahmen einer Vorlesung hinaus und appeliert an des Lehrers Fähigkeit zu geeigneter Auswahl. Ziel ist die Erziehung zur Raumanschauung, zum geometrischen Verständnis und zum tatsächlichen Konstruieren. Doch gibt der Mathematiker Bereis auch interessante Aufgaben und Bemerkungen für den mathematisch interessierten Leser.

Ob ein Werk dieses Umfangs und dieser detaillierten Gründlichkeit heute noch Berechtigung hat, scheint vielleicht zweifelhaft, besonders, dass es in mancher Beziehung elementar ist. So werden 50 Seiten den ebenen Kegelschnitten, ein ausführliches Kapitel den Durchdringungen ebenflächiger Körper gewidmet, während auf eine allgemeine Diskussion und Betrachtung auch nur der Flächen zweiter Ordnung verzichtet wird. Der grossen Ausführlichkeit entspricht auch der Stil der Zeichnungen, die mit oft störender Gewissenhaftigkeit alle Konstruktionslinien bringen. Sicher brachten die ausgezeichneten werke von E. Müller und Th. Schmidt (der Verfasser bekennt sich zur Wiener Schule der darstellenden Geometrie) das nötige auf wesentlich geringerem Raum. Und in dem theoretisch und zeichnerisch gleich schönen Werk

von F. Rehbock wird auf 200 Seiten die ganze darstellende Geometrie geboten, wobei allerdings manche Einzelheiten—wohl mit Recht—dem intelligenten Leser überlassen werden. Eine ähnliche Entwicklung zur Knappheit ist in den U.S.A. noch ausgeprägter.

Doch betrachtet der Verfasser sein Werk wohl mehr als ein Handbuch, ein Nachschlagewerk, das dem Lehrer und Praktiker gleicherweise zur Verfügung steht, und es sollte als solches gewertet werden.

Rossier, Paul 5142

Sur le théorème de Pythagore en géométrie affine.

Arch. Sci. Soc. Phys. Histoire Natur. Genève **16** (1963), 483–484.

Par le sommet A du triangle ABC, on mène une droite d; par B et C, on mène les parallèles à AC et AB qui coupent d en D et F; on construit les parallélogrammes $ABDE$ et $ACFG$, dont les côtés DE et FG se coupent en H. Par B et C, on mène BK et CJ équipollents à AH: L'aire du parallélogramme $BCKJ$ est égale à la somme des aires des parallélogrammes $ABDE$ et $ACFG$. La démonstration ne fait appel qu'à la congruence affine. C'est une généralisation du Théorème de Pythagore, dont l'auteur donne quelques cas particuliers.

Rossier, Paul 5143

Convergence de droites dans le triangle en géométrie affine.

Arch. Sci. Soc. Phys. Histoire Natur. Genève **16** (1963), 485–487.

Si l'on construit sur les trois côtés d'un triangle comme diamètres trois coniques homothétiques, elles se coupent deux à deux sur les supports des côtés, et les trois droites joignant ces points au sommet du côté opposé sont concourantes. Si l'un des points d'intersection de ces coniques est au milieu d'un côté, tous les trois le sont et l'on retrouve le théorème des médianes; si l'une des coniques est un cercle, toutes le sont et l'on obtient le théorème des hauteurs.

Hartmann, Heinrich; Lenz, Hanfried 5144

Quadriken und ihre Teilquadriken.

Arch. Math. **15** (1964), 302–309.

In einem projektiven Raum endlicher Dimension über dem Körper Q der rationalen Zahlen seien die Quadriken F, G (nicht notwendig gleicher Dimension) gegeben. Die Frage, wann G projektiv äquivalent zu einer Teilquadrik von F ist, wird (in die Sprache der Theorie der quadratischen Formen übersetzt) auf diejenigen Fragen zurückgeführt, die man bei Ersetzen von Q durch den Körper der reellen Zahlen bzw. durch die p-adischen Körper Q_p erhält.

Degen, Wendelin 5145

Projektive Zielbewegungen und darin erzeugbare konjugierte Netze.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 231–249.

Une famille de transformations d'un espace projectif en lui-même, dépendant d'un paramètre dit temps, constitue un mouvement projectif; les diverses images d'un point initial définissent sa trajectoire. Si à un instant donné les tangentes à toutes les trajectoires passent par un même point, on a affaire à un "Zielbewegung". Cette classe de mouvements jouit de propriétés remarquables, en particulier on peut les déterminer sans faire intervenir aucun signe d'intégration. A ces mouvements on peut associer, et à eux seulement, en partant d'une "trace" quelconque, un réseau conjugué de courbes; dans ce réseau, les transformées de Laplace d'un des systèmes de courbes sont planes, et la propriété réciproque caractérise ces "Zielbewegungen".

Die windschiefen Flächen mit ebenen Fallinien.

Österreich. Akad. Wiss. Math.-Natur. Kl. S.-B. II **172** (1963), 159–172.

Von W. Wunderlich [J. Reine Angew. Math. **208** (1961), 204–220; MR **27** #651] wurde die Frage aufgeworfen nach allen jenen windschiefen Regelflächen, welche lauter ebene Fallinien besitzen. Diese Frage wird hier vollständig beantwortet. Die synthetisch gehaltene Untersuchung des Problems geht aus von der Bemerkung, daß alle in den Punkten einer Erzeugenden e einer windschiefen Regelfläche Φ gelegten Falltangenten von Φ eine gewisse Cayleysche Regelfläche dritten Grades bilden und gewinnt durch das eingehende Studium verschiedener Lagemöglichkeiten der Erzeugenden e das Ergebnis: Die einzigen windschiefen Regelflächen mit ebenen Fallinien sind (1) die einschaligen Drehhyperboloide mit vertikaler Drehachse, (2) die durch aufrechte Ellipsenbewegung erzeugbaren geraden Konoide (4. Grades VII. Art nach R. Sturm). Als aufrechte Ellipsenbewegung bezeichnet man dabei nach J. Krames [Monatsh. Math. Phys. **46** (1937), 38–50] jene räumlichen Bewegungen, bei denen eine Gerade a in sich verschoben wird und ein beliebiger Raumpunkt P eine a schneidende Ellipse beschreibt, welche einem Drehzylinder mit der Mantellinie a angehört.

Levy, Harry 5147

★Projective and related geometries.

The Macmillan Co., New York; Collier-Macmillan, Ltd., London, 1964. x + 405 *pp*. $11.00.

This textbook on analytic geometry ("for undergraduate mathematics majors and beginning graduate students"), is restricted to two dimensions but makes a gallant attempt to be rigorous and consistent. In Chapter I the author introduces the Euclidean metric plane by means of ordered pairs of real numbers and a particular group of linear transformations. The crucial theorem that justifies this approach is stated on p. 49 without proof. Some geometers will not be happy to read (on p. 45) that "the processes of algebra and analysis are completely independent of geometry".

Chapter II (on projective spaces of dimension one) begins with a careful exposition of the idea of homogeneous coordinates over an arbitrary field in which $1+1\neq 0$. This is followed by a discussion of projectivities. The involution that interchanges two given pairs of points is described in terms of a pencil $\lambda Q_1+\mu Q_2$ of binary quadratic forms, with the conclusion that the invariant points (if any) of the involution are the roots of $\partial(Q_1, Q_2)/\partial(x_1, x_2)=0$.

In Chapter III (on projective spaces of dimension two), the author denotes a point by a column matrix $\mathbf{X}=(x_1, x_2, x_3)^T$ and a line by a row matrix $\mathbf{V}=(v_1, v_2, v_3)$, so that the condition for incidence is $\mathbf{VX}=0$ and the cross ratio of two points and two lines is

$$(VW, YZ) = \frac{\mathbf{VY}}{\mathbf{VZ}}\frac{\mathbf{WZ}}{\mathbf{WY}}.$$

The discussion of angular regions (called "sectors") could perhaps have been simplified by observing (on p. 134) that the four triangular regions formed by three nonconcurrent lines can be distinguished from one another by means of a fourth line that penetrates three of the regions while leaving the fourth untouched. In the proof of Desargues's two-triangle theorem (p. 144), the symbols $\lambda_i A_i$ and $\mu_i B_i$ might well have been abbreviated to A_i and B_i. On pp. 168 and 170, the author has interchanged the names Ceva and Menelaus.

Chapter IV provides a partially synthetic treatment of polarities and conics. The proof of Chasles's Theorem on p. 216 disregards the unpleasant possibility that the point C might lie on the line $A_1 \oplus B_1$.

Chapter V is on subgeometries of real projective geometry, namely, the affine plane (with a detailed discussion of sense), the hyperbolic line, the elliptic line, the Euclidean plane, the hyperbolic plane, the inversive plane, and the elliptic plane. He proves, for instance (on p. 297), that every equiaffine collineation is the product of two affine reflections. (Unhappily, he calls dilatations "dilations", disregarding the fact that, whereas "rotate" comes from the Latin "rotare", "dilate" comes from "dilatare".) In Theorem 8.4 (p. 339) he says that an opposite similarity is the product of a dilatation and three reflections; actually one reflection suffices. In Definition 9.4 (p. 361) he gives a parallel displacement the awkward name "infinite rotation", and defines it as the product of an even number of reflections in parallel mirrors; here two reflections suffice. The comparison of the projective and conformal models of the hyperbolic plane is neatly described on pp. 375–377.

There are numerous exercises (including some with hints and some with answers), excellent figures, a useful list of symbols, and an adequate index. {The only misprints noticed are "gives" for "give" in the middle of p. 62, and "i" for "it" on p. 157 (Theorem 9.3).}

Konstruktionen mit Lineal und Winkelübertrager in der hyperbolischen und euklidischen Ebene.

Publ. Math. Debrecen **10** (1963), 128–130.

Verfasser zeigt, dass die Systeme S_1 (Lineal mit Winkelübertrager) und S_2 (Lineal mit Streckenübertrager) in der hyperbolischen Ebene H äquivalente Instrumente sind, in der euklidischen Ebene E jedoch nicht. Man kann mit S_2 in E beliebige Winkel halbieren, aber nicht mit S_1.

O. Bottema (Delft)

Katz, Paul; Klee, Victor 5149

On the angle between two lines in a Minkowski plane.

Nieuw Arch. Wisk. (3) **12** (1964), 102–105.

Suppose E is a two-dimensional normed linear space with unit ball B, and L and M are two distinct lines through the origin in E. One of the two points of unit norm on L may be denoted by u_L. The distance from the point u_L to the line M is defined by

$$\delta(L, M) = \inf_{m\in M} \|u_L - m\|.$$

The authors investigate how the number $\delta(M, L)$ is related to the number $\delta(L, M)$ and find the following result:

$$\frac{\delta(L, M)}{1+\delta(L, M)} \leq \delta(M, L) \leq \min\left(1, \frac{\delta(L, M)}{1-\delta(L, M)}\right).$$

The condition under which equality holds is discussed.

Severi, Francesco 5150

★Funzioni quasi abeliane.

Seconda edizione ampliata. Pontificiae Academiae Scientiarum Scripta Varia, 20.

Pontificia Academia Scientiarum, Vatican City, 1961. 406 *pp*.

The first edition (1947) was reviewed in MR **9**, 578. The second edition consists of a reprint of the first (with reset type but apparently without any mathematical change of content), together with an appendix (improving the argument at one point) which contains (i) a reprint of the last part of a paper in Colloq. Fonctions de Plusieurs Variables (Bruxelles, 1953), pp. 9–20, G. Thone, Liège, 1953 [MR **15**, 521], (ii) a paper in Convegno Internaz. Geometria Differenziale (Italia, 1953), pp. 21–26, Edizioni Cremonese, Rome, 1954 [MR **16**, 163], and (iii) the text of the author's lecture in the Proc. Internat. Congr. Mathematicians, 1954 (Amsterdam), Vol. III, pp. 521–528, Noordhoff, Groningen, 1956 [MR **20** #5205].

Conforto's admirable review of the first edition, mentioned above, thus gives an adequate idea of the nature of the work. For developments, due in the main to Severi's pupils, we refer to the following review [#5151].

J. A. Todd (Cambridge, England)

Rosati, Mario 5151
★**Le funzioni e le varietà quasi abeliane dalla teoria del Severi ad oggi.**
Pontificiae Academiae Scientiarum Scripta Varia, 23.
Pontificia Academia Scientiarum, Vatican City, 1962. 194 *pp*.

This volume brings together in a convenient form extensions of the theory of quasi-abelian functions (see the preceding review [#5150]) due in the main to M. Benedicty and F. Conforto.

The first part of the book deals with the geometric theory of neutral domains on a curve, and extends to these, in a very complete way, the classical results of Hurwitz dealing with birational self-correspondences on an algebraic curve; this part of the theory is largely the creation of Benedicty. The remainder of the book is based on work, some of it posthumous, of Conforto, and is essentially a generalization of various aspects of the theory of Riemann matrices. This is by far the longer portion of the book, and contains a wealth of important and interesting results. There is a full bibliography of the subject at the end.

Those interested in the theory of quasi-abelian functions will be indebted to the author for this connected account of modern developments of the subject.

J. A. Todd (Cambridge, England)

Lüneburg, Heinz 5152
Finite Möbius-planes admitting a Zassenhaus group as group of automorphisms.
Illinois J. Math. 8 (1964), 586–592.

Let M be a finite Möbius plane [cf. Benz, Jber. Deutsch. Math.-Verein. **63** (1960), Abt. 1, 1–27; MR **22** #7012]. The only known types of such planes are the Miquelian planes (in some sense analogous to the Desarguesian planes of projective geometry) and the planes derived from the ovoid in Tits's presentation of the Suzuki groups [Tits, Arch. Math. **13** (1962), 187–198; MR **25** #3990]. The result of this paper is that M is in effect of one of these types if there is an automorphism group of M operating doubly transitively on the points of M and such that only the identity automorphism leaves three different points of M invariant. Any such group characterizes M up to isomorphism. (If the number of points on a circle of M is odd, then the finite Möbius plane M is of one of the above types. This result was recently announced by Dembowski [Bull. Amer. Math. Soc. **69** (1963), 850–854; MR **27** #5165].)

O. H. Kegel (Frankfurt a.M.)

Lüneburg, Heinz 5153
Charakterisierungen der endlichen desarguesschen projektiven Ebenen.
Math. Z. **85** (1964), 419–450.

Let $\mathscr{E}$ be a projective plane of finite order n and suppose that $\mathscr{E}$ is (X, PX)-transitive for some point P and all points X on some line g not containing P. (PX is the line joining P and X.) Then $\mathscr{E}$ is probably desarguesian. This conjecture is strongly supported by the paper under review. Failing to prove it in full generality, the author shows that it is true under any one of the following additional assumptions (here Δ denotes the group generated by all (X, PX)-collineations): (1) n is even, and all involutions of Δ are perspectivities (Satz 5); (2) n is even and not a square (Korollar 3, a simple consequence of Satz 5); (3) n is even, and $\mathscr{E}$ is (P, g)-transitive (Korollar 3); (4) n is odd, and Δ contains only one involution (Satz 6); (5) $n \equiv 3 \bmod 4$ (Korollar 5); (6) any collineation of Δ fixes either all or at most two points of g (Satz 7 (d)). {In the meantime the author has proved that the following condition also implies $\mathscr{E}$ to be desarguesian: $\mathscr{E}$ is (P, g)-transitive, and all involutions in the group generated by all (X, PX)- and (P, g)-collineations are perspectivities. This is an improvement of (1) and (4) above.}

Before proving these results, the author gives some preparations of independent interest. He begins with the following theorem (Satz 1): If the group H satisfies $PSL_2(q) \leq H \leq P\Gamma L_2(q)$ and if H possesses a doubly transitive permutation representation, then the degree of this representation is, with finitely many exceptions, equal to $q+1$. The exceptions (all for $q \leq 11$) are enumerated. This result is the main tool for the following characterizations of the finite desarguesian projective planes. Let $\mathscr{E}$ be a projective plane of prime power order q, and suppose that $\mathscr{E}$ has a collineation group Δ isomorphic to either (i) $SL_2(q)$ [here it is also postulated that, in case q even, every involution of Δ be a perspectivity] or (ii) $PSL_2(q)$ [in this case Δ is supposed to have an orbit of length $q+1$]. In both cases $\mathscr{E}$ is desarguesian (Satz 2 and Satz 3), and it is also determined how Δ must operate on $\mathscr{E}$ (Korollar 1 and Korollar 2). The proofs are highly nontrivial; they use some of the deepest recent results in finite group theory.

P. Dembowski (Frankfurt a.M.)

Barlotti, Adriano 5154
Sul gruppo delle proiettività di una retta in sè nei piani liberi e nei piani aperti.
Rend. Sem. Mat. Univ. Padova **34** (1964), 135–159.

The author considers the group G_r of projectivities (that is, finite products of perspectivities) on a line in free projective planes (in the sense of Marshall Hall). Among other results, the following are proved. (I) G_r contains no element, other than the identity, of finite period. (II) Any two elements of G_r which commute are contained in a cyclic subgroup. (III) G_r cannot be more than quintuply transitive on the points of the line. (In a footnote, the author mentions that, in a paper to be published, J. Joussen has proved that in fact G_r is triply transitive.) The author points out that these theorems are valid for a more extended class of projective planes.

J. A. Todd (Cambridge, England)

Dress, Andreas 5155
Eine geometrische Charakterisierung Desarguesscher Ebenen mit bewertetem Koordinatenkörper.
Abh. Math. Sem. Univ. Hamburg **27** (1964), 199–205.

The reviewer proved [Math. Ann. **132** (1956), 180–200; MR **18**, 667] that the existence of a homomorphism φ of a projective plane $P(K)$ over a field K onto the projective plane $P(\bar{K})$ of the field $\bar{K}$ implies that there is a valuation ring A in K, with maximal ideal I, such that A/I is isomorphic to $\bar{K}$ and such that φ is given as the composition of an isomorphism of $P(K)$ onto itself with the natural homomorphism of $P(A)$ (that is, the projective plane over the ring A as defined) onto $P(A/I) = P(\bar{K})$. In the

present paper the author attempts successfully a description of φ in the plane $P(K)$ itself, without referring to the image plane. For that purpose he defines a relation on the quadruples $(ABCD)$ of points of $P(K)$ as a property satisfying the following five conditions: (i) A, B, C, D are collinear and $A \neq D$ and $B \neq C$, (ii) for Menelaus configurations E, A_i, B_i, C_i $(i = 1, 2, 3)$ with collinear C_i, $(A_1C_2A_3B_3)$ implies $(A_1C_3A_3B_2)$ or $(A_3C_1A_2B_1)$, (iii) $(ABCD)$ and $(ADCB)$ do not hold simultaneously, (iv) $(ABCD)$ implies $(BACD)$, (v) there are three points A, B, C satisfying $(AABC)$. It turns out that the cross ratios of the points A, B, C, D satisfying the above relation form a maximal ideal of a valuation ring of K. The paper concludes with the description of a method to determine the homomorphism φ: $P(K) \rightarrow P(\bar{K})$ if one knows only the image of a projective frame in $P(K)$ and the associated valuation ring A in K.

W. Klingenberg (Mainz)

Dress, Andreas 5156

Metrische Ebenen und projektive Homomorphismen.

Math. Z. **85** (1964), 116–140.

Diese Arbeit stellt einen wichtigen Beitrag zur Strukturuntersuchung der metrischen Teilebenen E einer projektiv-metrischen Ebene $P(V)$ im Sinne von Bachmann [*Aufbau der Geometrie aus dem Spiegelungsbegriff*, Springer, Berlin, 1959; MR **21** #6557] dar. Das wesentliche Hilfsmittel dabei ist der Begriff des Homomorphismus von $P(V)$, wie er vom Referenten [Math. Ann. **132** (1956), 180–200; MR **18**, 667] eingeführt wurde. Wir erinnern daran, dass ein Homomorphismus φ einer projektiven Ebene $P(V)$, die aus einem Vektorraum V über dem Körper K hergeleitet ist, auf eine projektive Ebene $P(\bar{V})$, die aus einem Vektorraum über dem Körper $\bar{K}$ hergeleitet ist, Anlass gibt zu einem Bewertungsring R in K mit maximalem Ideal I so dass R/I isomorph zu $\bar{K}$ ist. Die zugehörige Primstelle von K werde mit $\mathfrak{p}$ bezeichnet. Seien nun überdies $P(V)$ und $P(\bar{V})$ projektiv-metrische Ebenen. Dann betrachten wir nur Homomorphismen φ, die mit dieser Struktur verträglich sind. Das Hauptergebnis der Arbeit gibt nun eine Charakterisierung der bezüglich $\mathfrak{p}$ pseudokonvexen metrischen Teilebenen E von $P(V)$ (zu diesem Begriff sei auf die Arbeit verwiesen) durch Eigenschaften ihrer Bilder unter dem Homomorphismus φ auf $P(\bar{K})$. Wie der Verfasser ankündigt, hat dieses Ergebnis weitreichende Folgerungen für den Fall, dass K nicht formal reell und perfekt für $\mathfrak{p}$ ist, da in diesem Falle jede Teilebene E von $P(V)$ bezüglich $\mathfrak{p}$ pseudokonvex ist. In diesem Falle ist also die Strukturuntersuchung der Teilebenen E von $P(V)$ reduziert auf die Untersuchung der Teilebenen in $P(\bar{V})$. Insbesondere wird hierdurch dann eine vollständige Bestimmung der metrischen Teilebenen E über lokalen Körpern gelingen, was in einer späteren Arbeit ausgeführt werden soll.

Über die Schattengrenzen konvexer Körper. (Konvexe Körper und Konvexität auf Grassmann-Kegeln. VII).

Abh. Math. Sem. Univ. Hamburg **27** (1964), 167–170.

Part VI (by Shephard) appeared in J. London Math. Soc. **39** (1964), 307–319 [MR **29** #520]. Let K be contained in Euclidean n-space R^n. Let $\mathscr{R}$ be an arbitrary r-dimensional subspace of R^n through a fixed point z, $1 \leq r \leq n-1$. The $(n-1)$-dimensional supporting spaces of K which are at right angles to $\mathscr{R}$ form a cylinder $Z(K, \mathscr{R})$. The set $S(K, \mathscr{R}) = Z(K, \mathscr{R}) \cap K$ is called an r-shadow-boundary of K. It is sharp if every generator of $Z(K, \mathscr{R})$ has precisely one point in common with K. The main theorem is that, for all $\mathscr{R}$ except a set of measure zero (with a suitably defined measure), $S(K, \mathscr{R})$ is sharp.

Grünbaum, B. 5160

A proof of Rogers' conjecture of pairs of convex domains.

J. London Math. Soc. **39** (1964), 697–702.

The following conjecture of Rogers is proved. Let K_1, K_2 be plane convex bodies; unless both bd K_1 and bd K_2 are ellipses, there is an affine transformation T such that $TK_2 \subset K_1$ and bd $K_1 \cap$ bd TK_2 has at least three connected components.

A. M. Macbeath (Birmingham)

Pliś, A.; Turowicz, A. 5161

On chords of convex bodies.

Colloq. Math. **12** (1964), 87–89.

The following (already well-known) result is proved: For any chord that passes through the centroid c of an n-dimensional convex body, let q be the ratio of the lengths of the two parts into which it is divided by c. Then $n^{-1} \leq q \leq n$. References to earlier proofs of this and related results will be found in a paper of B. Grünbaum [Proc. Sympos. Pure Math., Vol. VII, pp. 233–270, Amer. Math. Soc., Providence, R.I., 1963; MR **27** #6187].

G. C. Shephard (Birmingham)

Rubinšteĭn, G. Š. 5162

Theorems on the separation of convex sets. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 1098–1124.

The author's announcements [Dokl. Akad. Nauk SSSR **78** (1951), 213–215; MR **13**, 45; ibid. **102** (1955), 451–454; MR **17**, 185; ibid. **152** (1963), 288–291; MR **28** #1983] have stressed the geometric nature of his proofs. This claim is now made formal by doing everything in a "generalised vector space" whose structure consists merely of a family of copies of the ordered set of real numbers ("axes"), one

containing each ordered pair of distinct points x, y, reversing with (x, y), and satisfying the axiom of Pasch.

The question naturally arises whether such a space is really more general than a linearly open convex set in a real vector space. The author shows that it is, by giving a two-dimensional example in which the extremal parallel relation for rays is not symmetric. However, all such examples are maximal, at least in the sense that a generalized vector space not embeddable in a generalized vector space with unique parallels is neither a subspace with codimension >0 nor a proper factor space of any generalized vector space. {Generalized vector spaces with unique parallels seem to be vector spaces, but the author says nothing about it.} *J. R. Isbell* (New Orleans, La.)

Fejes Tóth, László 5163

Über eine Extremaleigenschaft der affin-regulären Vielecke. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 299–302 (1964).

The author gives a simplified proof of a theorem of A. Rényi and R. Sulanke [Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **2** (1963), 75–85; MR **27** #6190]: Let T be a convex n-gon, in the plane, of area Δ, and let $t_1, \cdots, t_n$ be the areas of the triangles defined by three consecutive vertices of T. Then $x = t_1 t_2 \cdots t_n/\Delta^n$ attains its maximum when T is affine regular.

In the proof, we let T be a polygon for which x attains its maximum value (such exists by Weierstrass' Theorem), and consider an infinitesimal movement of one vertex of T. The author shows, by a geometrical and analytical argument, that x may be increased unless T is affine regular. *G. C. Shephard* (Birmingham)

Hajós, G. 5164

Über eine Extremaleigenschaft der affin-regulären Polygone. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 293–297 (1964).

This paper presents another proof of the theorem of A. Rényi and R. Sulanke stated in the preceding review [#5163]. The author shows by a simple geometrical argument that if T is an n-gon for which x attains its maximum value, then for each pair of vertex-regions of T there is an "affine-symmetry" (a transformation of the type SRS^{-1}, where S is an affine transformation and R is a Euclidean reflection) which transforms one into the other. (A vertex-region is the cone of projection of T from a vertex of T.) The major part of the proof consists of showing that if this condition is satisfied, then T must be affine-regular.

The author also shows that if a polyhedron P, in three dimensions, has the property that each pair of vertex-regions are "affine-symmetric", then P must be either a tetrahedron or an affine-regular octahedron. *G. C. Shephard* (Birmingham)

Erdős, P.; Rogers, C. A. 5165

The star number of coverings of space with convex bodies.

Acta Arith. **9** (1964), 41–45.

If we are given a covering of a space by a system of sets, the star number of the covering is the supremum, over sets of the system, of the cardinals of the numbers of sets of the system meeting a set of the system. In view of the results of dimension theory, it is natural to conjecture that any covering of R^n by closed sets of uniformly bounded diameter has star number at least $2^{n+1}-1$. This has been proved, for $n=2$, by V. Boltjanskiĭ [Dokl. Akad. Nauk SSSR **75** (1950), 605–608; MR **13**, 149; errata, MR **13**, p. 1139].

In this paper only coverings of R^n by translates of a fixed convex body are considered, and the following are proved. Theorem 1: The star number of a lattice covering of R^n by translates of a closed centrally-symmetric convex body is at least $2^{n+1}-1$. Theorem 2: Provided n is sufficiently large, if K is a closed convex body with difference body DK, there exists a covering of R^n by translates of K with star number less than $(n \log n + n \log\log n + 4n + 1)(V(DK)/V(K))$, where the ratio of the volumes $V(DK)/V(K)$ is at most $\binom{2n}{n}$, in general, and equals 2^n if K is centrally-symmetric. The proof of Theorem 2 is a modification of the method used in a previous paper by P. Erdős and C. A. Rogers [Acta Arith. **7** (1961/62), 281–285; MR **26** #6863]. *G. C. Shephard* (Birmingham)

Leech, John 5166

Some sphere packings in higher space.

Canad. J. Math. **16** (1964), 657–682.

In the first part of this paper the densest lattice packings of equal spheres in four and eight dimensions are generalized to obtain a packing in 2^m dimensions in which each sphere is touched by $\prod_{r=1}^{m}(2^r+2)$ others.

In the second part of the paper analogues of the densest lattice packing in eight dimensions are generalised to obtain new packings in twelve and twenty-four dimensions. In the packing in twelve dimensions, each sphere is touched by 648 others, in twenty-four dimensions each sphere is touched by 98256 others. The lattices associated with these packings seem to be connected with the Steiner systems $S(5, 6, 12)$ and $S(5, 8, 24)$. Packings in spaces of lower dimension are derived by taking suitable linear sections.

The third part of the paper connects the number of spheres touching a given sphere of the packing, and the density of the packing, with the upper bounds determined by Coxeter [Proc. Sympos. Pure Math., Vol. VII, pp. 53–71, Amer. Math. Soc., Providence, R.I., 1963; MR **29** #1581] and Rogers [Proc. London Math. Soc. (3) **8** (1958), 609–620; MR **21** #847]. *J. A. Todd* (Cambridge, England)

Finn, Robert 5167

On normal metrics, and a theorem of Cohn-Vossen.

Bull. Amer. Math. Soc. **70** (1964), 772–773.

Let S be a finitely connected surface with a Riemannian metric with respect to which it is complete and has finite

curvatura integra C. Then a neighborhood of each boundary component can be mapped conformally onto the punctured disk $0<|z|<1$. For $0<r_1<r_2<1$, let $L(r_1)$ be the length in the metric of $|z|=r_1$, and $A(r_1, r_2)$ the area in the metric of the annulus $r_1 \leq |z| \leq r_2$. The author considers a class of metrics for which he is able to prove the following theorem: The quantity $L^2(r_1)/A(r_1, r_2)$ tends to a finite limit as $r_1 \to 0$. If we denote this limit at the jth boundary component by $4\pi\nu_j$, then $C=2\pi(\chi-\sum\nu_j)$, where χ is the Euler characteristic of S.

Since obviously $\nu_j \geq 0$, this sharpens the classical result of Cohn-Vossen that $C \leq 2\pi\chi$ for the class of metrics considered. No proofs are given. {There is a misprint in the definition of ν_j in the paper. The numerator should be squared.} *R. Osserman* (Stanford, Calif.)

Giering, Oswald 5168

Über das Krümmungsverhalten der einer Fläche umschriebenen Torsen.

Monatsh. Math. **68** (1964), 193–212.

This paper, written in the style of classical differential geometry, uses the duality between space curves and developables as a heuristic method for the discovery of theorems about the curvature of developables circumscribing a surface. The main notion, corresponding to that of normal curvature, is the conical curvature of a developable in a ruling; this is the limit of the ratio of the angle of neighboring tangent planes to the angle of the corresponding rulings. The dual of the theorems of Meusnier and Euler for the normal curvatures is the theorem of Mannheim [E. Müller, Akad. Wiss. Wien Math.-Natur. Kl. S.-B. Abt. IIa **126** (1917), 311–318]. The dual of the fact that the curvature properties of curves on a surface can be studied on plane sections is that all developables circumscribing a surface along curves with a common osculating plane in some point have the same point of striction (or regression) and the same conical curvature for the common ruling, therefore the curvature properties of the developables can be studied on the surfaces circumscribing the sections of osculating planes. This leads to very detailed theorems, in particular, to a formula for the radius of conical curvature in dependence on certain normal curvatures, and to the proof that the conical curvature is invariant in the Gaussian map. Finally, the connection with previous constructions by E. Kruppa and C. Segre is indicated.

Gorowara, Krishan K. 5170

A problem in rectilinear congruences using tensor calculus.

Riv. Mat. Univ. Parma (2) **4** (1963), 159–165.

Une surface S étant regardée comme la surface de référence d'une congruence rectiligne, l'auteur, utilisant le calcul tensoriel, donne deux expressions générales de la courbure K d'une courbe quelconque C de S en l'un quelconque (x) de ses points, mettant en jeu la position du rayon de la congruence issu de (x) et la courbure normale de S suivant la direction de C. Diverses applications sont faites de ces formules, concernant les cas où les rayons de la congruence envisagée sont normaux à S ou bien situés dans l'une des faces du trièdre de Frenet de la courbe C.

Minkwitz, G. 5171

Über das Verhalten der Hauptkrümmungsdifferenz in der Umgebung einer Nabelpunktslinie.

Monatsb. Deutsch. Akad. Wiss. Berlin **5** (1963), 411–414.

The object of study is a surface in E^3 having a plane curve of symmetry C consisting of umbilics. One result is the following: If k_1, k_2 are the principal curvatures at each point, and if we let $A=|k_1-k_2|$ be the "astigmatism" of the surface at each point, then along C we have $\partial A/\partial n = \pm 2dk/ds$, where k and s are the curvature and arc length, respectively, of C. *R. Osserman* (Stanford, Calif.)

Vogler, Hans 5172

Die auf einer Torse verlaufenden Linien konstanten Gratabstandes als duale Seitenstücke zu den pseudorektifizierenden Torsen einer Raumkurve.

Österreich. Akad. Wiss. Math.-Natur. Kl. S.-B. II **172** (1963), 173–187.

In einer früheren Note [dieselben S.-B. **171** (1962), 173–188; MR **27** #1884] hat der Verfasser die pseudorektifizierenden Torsen einer Raumkurve k studiert, d.h. jene Torsen, auf denen k pseudogeodätische Linien im Sinne von W. Wunderlich [Österreich. Akad. Wiss. Math.-Nat. Kl. S.-B. IIa **158** (1950), 61–73; MR **12**, 742; ibid. **158** (1950), 75–105; MR **12**, 742] sind, d.h. solche Linien, deren Schmiegebenen gegen die Torse unter festen Winkeln geneigt sind. In der vorliegenden Arbeit wird die dazu duale Figur untersucht, nämlich jene Kurven $\mathfrak{y}$ auf einer Torse, deren Punkte von der Gratlinie $\mathfrak{x}$ der Torse Θ einen festen, auf den Tangenten der Gratlinie gemessenen Abstand (konstanten Gratabstand) haben. Bei der Bewegung des begleitenden Dreibeins D der Gratlinie der Torse längs der Gratlinie $\mathfrak{x}$ beschreibt jeder Punkt der Tangente eine der möglichen Linien $\mathfrak{y}$ konstanten Gratabstandes der Torse. Die Bewegung des begleitenden Dreibeins D längs der Gratlinie ist in jedem Augenblick eine euklidische Schraubung (begleitende Schraubung S). Die Bahntangenten dieser Schraubung S bilden einen quadratischen Kollineationskomplex K mit der Segreschen Charakteristik [(11)(22)]. Dessen Grundfiguren (Komplexparabeln, Komplexkegel, kubische Ordnungskreise, kubische Ordnungstorsen usw.) spielen naturgemäß bei der Untersuchung jener Gebilde eine große Rolle, welche in jedem Augenblick von den Bahntangenten, Bahnschmiegebenen usw. der Punkte, Kanten und Ebenen des begleitenden Dreibeins D erzeugt werden. Natürlich gehören auch die Krümmungsachsen der Bahnkurven der begleitenden Schraubung S dem gleichen Komplex K an, woraus sich eine Reihe entsprechender Sätze ergibt. Als Beispiele der erzielten Ergebnisse erwähnen wir die folgenden Sätze: Sind die

Tangenten einer Kurve $\mathfrak{y}$ festen Gratabstandes einer Torse Θ mit dem begleitenden Dreibein D der Gratlinie $\mathfrak{x}$ von Θ starr verbunden, so ist die Gratlinie $\mathfrak{x}$ von Θ ein kubischer Kreis. Ermittelt man in den Punkten einer Erzeugenden e für die einzelnen Linien festen Gratabstandes der Torse Θ (1) die Hauptnormalen, (2) die Binormalen, (3) die Streckebenen, so erhält man (1) eine Regelfläche 4. Grades (mit der Erzeugenden e als einfacher und der Krümmungsachse a der Gratlinie als dreifacher Leitgeraden), (2) eine Regelfläche 3. Grades (mit der Erzeugenden e als einfacher und der Krümmungsachse a als doppelter leitgeraden), (3) eine Torse vierter Klasse.

Pinl, M. 5173

Über einen Satz von G. Ricci-Curbastro und die Gauss'sche Krümmung der Minimalflächen. II.

Arch. Math. **15** (1964), 232–240.

Part I appeared in same Arch. **4** (1953), 369–373 [MR **15**, 554]. The theorem referred to in the title gives an intrinsic characterization of the first fundamental form of a minimal surface in E^3. Namely, given a Riemannian metric g_{ij} with corresponding Gauss curvature K, this metric is realized (locally) by a minimal surface in E^3 if and only if the metric $g_{ij}^* = \sqrt{(-K)}g_{ij}$ is flat (i.e., $K^* \equiv 0$). This property does not hold in general for minimal surfaces in E^n, $n > 3$. The author investigates conditions on a surface so that it will hold, together with related properties.

Construction of the relative normal in P_2. (Slovak. Russian and English summaries)

Acta Fac. Natur. Univ. Comenian. **9**, 95–98 (1964).

Author's summary: "Let $C: R(t)$ be a projective plane curve. Its tangent and the relative normal in the point R we denote by RT and RN. It is possible that the t is a projective arc. In this case the relative normal is changed into a projective normal whose construction is known. In the article we give the construction of the relative normal in the case when t is not necessarily an arc. It is clear that this construction depends on a parametrisation of the curve C."

Jůza, Miloslav 5176

Le système monoparamétrique des plans dans l'espace S_6.

Comment. Math. Univ. Carolinae **4** (1963), 99–101.

On considère dans l'espace projectif S_6 les variétés $V_{2,6}$, formées par un système monoparamétrique de plans $[y_0(t), y_1(t), y_2(t)]$, dont les courbes directrices $y_i(t)$ sont définies par certains systèmes d'équations différentielles. On donne ensuite, sans démonstrations, les conditions pour que la courbe $x = \sum a_0{}^i y_i(t)$ sur $V_{2,6}$ soit une quasi-asymptotique d'ordre 1, 2, ou 3.

Picasso, E. 5178

Superficie differenziabili dello spazio proiettivo a cinque dimensioni.

Rend. Mat. e Appl. (5) **22** (1963), 392–415.

Ce travail est consacré à l'étude locale d'une surface V_2 de l'espace projectif S_5, dans une région à comportement régulier, tant pour l'espace 2-osculateur au point générique (x) que pour le système quintuple des lignes principales. L'auteur apporte à ce sujet une intéressante contribution personnelle relative à la généralisation de certains éléments fondamentaux de la géométrie des surfaces de l'espace projectif ordinaire, tels par exemple le repère normal de Fubini ou la quadrique de Lie des V_2 de S_3. La surface V_2 étant représentée par le système fondamental $[x_{rs} = c_{rs}^{\lambda\mu} x_{\lambda\mu},\ r, s, t = 1, 2, 3;\ \lambda, \mu = 0, 1, 2]$, il montre comment en associant à chacun de ses points un hyperplan tangent ξ et en envisageant la variété tangentielle W engendrée par ξ, on peut, en utilisant la condition en coordonnées locales d'appartenance d'un point et d'un hyperplan, former un système d'équations linéaires (indépendantes si ξ est générique) invariantes par rapport aux deux variétés V_2 et W, auquel se trouvent rattachés un repère local de V_2 et un repère local de W. Un tel rattachement n'est pas intrinsèque; les repères précédents dépendent, en dehors des équations fondamentales, des coordonnées de la droite intersection de ξ avec le plan des trois points dérivés seconds de (x). Si ξ est l'un des cinq hyperplans cupsidaux en (x), les deux repères corrélatifs attachés à V_2 et à W dépendent des équations fondamentales et de la direction dv/du de la section de V_2 par ξ, et en choisissant pour cette direction l'une des cinq directions principales on obtient, pour chaque point (x), des repères et des hypersurfaces du $2^{\text{ième}}$ ordre associées, à partir desquels il est possible de construire un repère et une hypersurface du $2^{\text{ième}}$ ordre intrinsèquement liés à V_2. L'auteur montre l'usage que l'on peut faire de ces deux éléments intrinsèques pour la construction géométrique de certains invariants infinitésimaux de contact.

Stanilov, G. 5179

Minimal lines in a bi-axial geometry. (Bulgarian)

Fiz.-Mat. Spis. Bŭlgar. Akad. Nauk. 7 (40) (1964), 51–53.

The author gives an elementary proof of the property shown by Ivanov [C. R. Acad. Bulgare Sci. 15 (1962), 697–698; MR 26 #4270] that the geodesic lines of the first kind, defined as those surface curves whose osculating planes contain the corresponding previously defined first normal of the surface, minimize a certain lineal element.

B. S. Popov (Skopje)

Terracini, Alessandro 5180

Elementi curvilinei composti e trasformazioni puntuali.

Math. Notae 19 (1964), 11–21.

L'auteur rappelle la définition d'un élément curviligne composé $E_{2,m}$, de support $Oo\omega$, commun à toute une famille de courbes passant par O, tangentes en ce point à une droite o issue de O, et admettant pour plan osculateur en O le plan ω passant par o. Il cherche s'il est possible qu'une transformation ponctuelle T change un élément composé en un élément composé. Il montre: (a) Soient O, O' deux points homologues dans T, o et o' deux directions homologues issues de O, O'; si aux courbes issues de O tangentes à o et ayant en O un plan osculateur donné ω, la transformation T fait correspondre des courbes issues de O' tangentes à o' et ayant en O' un plan osculateur donné ω', alors à tout élément composé $E_{2,m}$ de support $Oo\omega$ correspond par T un élément composé $E'_{2,m}$ de support $O'o'\omega'$. (b) Étant donné T, O, O', o, o', si les droites o, o' ne sont pas droites caractéristiques, il existe un seul couple de plans ω, ω' se trouvant dans les conditions de (a) et si ces droites o, o' sont caractéristiques, le plan ω est indéterminé. (c) Tout couple d'éléments composés qui se correspondent dans une transformation ponctuelle s'obtient nécessairement par le procédé de (a).

Mikan, Milan 5183

Möbius geometry and non-Euclidean geometry of one-parameter sets. (Czech. Russian and French summaries)

Rozpravy Československé Akad. Věd 73 (1963), no. 18, 90 pp.

L'ensemble (x) à un paramètre de sphères non-singulières x dans un espace M_3 de Möbius est défini comme un système de sphères dont les coordonnées pentasphériques x_i $(i=1,\cdots,5)$ sont des fonctions réelles d'un paramètre réel invariant s qui admettent dans l'intervalle $\langle 0, s_1\rangle$ des dérivées finies de tous les ordres par rapport à s. Ces coordonnées sont interprétées comme des coordonnées de Weierstrass des points x d'un espace hyperbolique P_4 à quadrique fondamentale elliptique réelle K à trois dimensions. L'image de l'ensemble (x) de sphères est une courbe (x) dans P_4 qui n'est pas situé dans un hyperplan de P_4 si et seulement si le Wronskien W_x de (x) est de rang $h_x=5$. Dans ce cas seulement l'image de l'ensemble (y) de sphères y orthogonales aux sphères x, $x^{\cdot}$, $x^{\cdot\cdot}$, $x^{\cdot\cdot\cdot}$ $(x^{\cdot}=dx/ds$, etc.) des ensembles (x), $(x^{\cdot})$, $(x^{\cdot\cdot})$, $(x^{\cdot\cdot\cdot})$ est une courbe. On a $h_x=5$ implique $h_y=5$ et on ne considère que le cas en question. Soient $y'=dy/du$, etc., les dérivées de y par rapport au paramètre invariant u de (y). On construit une sphère $\xi\equiv\eta$ telle que les sphères x, $x^{\cdot}$, y, y', $\xi\equiv\eta$ sont orthogonales deux à deux. Leurs images forment un simplex polaire par rapport à K. On l'appelle simplex conjoint des ensembles (x), (y) et on dit que les ensembles en question sont réciproques. Les relations entre les sphères singulières dans les faisceaux déterminés par x, $x^{\cdot}$ et x, y' permettent de distinguer trois cas spéciaux. On établit le système complet des invariants de l'ensemble (x), ainsi que les invariants de l'ensemble réciproque (y), ceux-ci étant déterminés par les invariants de (x) et inversement. En supposant que tous les invariants de (x) et (y) soient différents de zéro on examine leurs relations aux Wronskiens des deux ensembles et on établit les formules de Frenet, ainsi que les équations naturelles des deux ensembles réciproques. Les invariants en question sont en même temps invariants des enveloppes X, Y des ensembles (x), (y), les images de X, Y étant des surfaces réglées dont les droites, dans le cas de l'enveloppe réelle, ne coupent pas la quadrique K. On explique aussi la signification de l'annulation des invariants mentionnés. Les formules de Frenet ont, pour chaque position initiale du simplex conjoint une solution. Les résultats généraux sont appliqués ensuite au cas d'ensembles (x) à invariants constants. Dans ce cas, les courbes $(x^{\cdot})$, (y') se trouvent situées dans un même hyperplan C. Les formules de Frenet deviennent maintenant le système d'équations différentielles de d'Alembert. L'équation caractéristique de ce système a cinq racines dont une est toujours nulle, tandis que les autres forment deux couples de racines qui ne diffèrent que par le signe. On discute en détail la solution du système formé par les formules de Frenet. Une transformation infinitésimale qui reproduit une courbe (x) donnée à invariants constants s'appelle transformation G. On déduit les conditions nécessaires et suffisantes pour que les coordonnées des points de la courbe (x), reproduite par G, soient normalisées et pour que le paramètre sur (x) soit invariant, ainsi que les conditions nécessaires et suffisantes pour que G soit un mouvement hyperbolique dans P_4. L'ensemble de toutes les courbes (x) à invariants constants dépend de 13 paramètres, l'ensemble des transformations G est à 10 paramètres. Une transformation G reproduit un ensemble à trois paramètres de courbes (x) dont une seule passe par un point donné. On construit ensuite un groupe à un terme engendré par la transformation G reproduisant un ensemble de courbes (x) comme un sous-groupe de mouvements hyperboliques dans P_4. La transformation G

reproduit aussi les courbes (y) réciproques aux courbes (x) reproduites par la même transformation G, ainsi que les autres courbes engendrées par les sommets du simplex conjoint. On définit et on étudie encore les courbes osculatrices à invariants constants à une courbe donnée.

Metric invariants and covariants of pairs of planes in a quasi-elliptic space. (Russian. Lithuanian and English summaries)
Litovsk. Mat. Sb. 4 (1964), 241–253.
Authors' summary: "In this article is found an effective method of determination of metrical invariants and covariants of couples of planes in a space with projective metric—the quasielliptic space, that is, the space with an absolute consisting of an imaginary cone of second order and a non-degenerate quadric in a summit plane of this cone. The metrical covariants of couples of planes are analogous to the perpendiculars of couples of planes in non-Euclidean spaces. The metrical invariants are analogous to the lengths of these common perpendiculars. The points of intersection of the metrical covariants of two planes with these planes are determined by means of eigenvectors of some matrices formed by the matrix coordinates of the planes. The matrix invariants are determined by means of eigenvalues of the matrices. These matrices are formed by various ways for the metrical covariants being in lines not intersecting with the summit plane of the absolute, intersecting with this plane and entirely being in this plane." *M. Kawaguchi* (Sapporo)

★**On a general phenomenological differential principle.**
Edited by Tatomir P. Angelitch (Anđelić). The Serbian Academy of Sciences and Arts Monographs, Vol. CCCLXVIII, the Section of Natural and Mathematical Sciences, Vol. 32.
Naučno Delo, Belgrade, 1964. ix + 141 *pp*. *Din.* 1500.00.

The linear differential form $\Phi = \sum_{i=1}^{N} X_i dx_i$ is called Pfaff's linear form or Pfaff's expression after Johann Friedrich Pfaff, who founded the theory of such differential forms. Pfaff's expression and Pfaff's equations are closely related to other mathematical concepts, which occupy an important place in modern mathematics. Applications of integral invariants were made by H. Poincaré, E. Cartan and G. Birkhoff for the first time, and the relationships between the theory of integral invariants and Pfaff's expression underlines the importance. On the other hand, the so-called Pfaff method in mechanics was presented for the first time by E. T. Whittaker in 1904. The relation between Pfaff's expression and differential equations in canonical form was established by G. Prange and E. Schering.

In his preface the author first gives the phenomenological interpretation of a principle of mechanics which is called Pfaff's principle and the substance of which, in a different form, has been known for quite a long time. The applications of that principle have proved to be very convenient, its theory being, especially in recent time, evaluated very intensively. Then, he uses that principle for the formulation of a general phenomenological differential principle. The phenomenological derivation of that principle and the phenomenological interpretation of its procedure, i.e., its algorism, is the main purpose of this treatise.

In Chapter 1, he speaks of the history of the Pfaff principle, and Chapter 2 is devoted to the phenomenological interpretation of Pfaff's principle in mechanics. Chapter 3 is concerned with the same interpretation in celestial mechanics. An interpretation in the mechanics of variable masses is considered in Chapter 4. Chapter 5 is devoted to an interpretation in physics. In Chapter 6 he makes general remarks on the phenomenological principle. The bibliography at the end of this treatise is extensive.

K. Takano (Tokyo)

Misner, Charles W. 5193

Differential geometry and differential topology.
Relativité, Groupes et Topologie (*Lectures, Les Houches*, 1963 *Summer School of Theoret. Phys., Univ. Grenoble*), *pp.* 881–929. *Gordon and Breach, New York*, 1964.

This highly mathematical, perfectly readable, article begins by defining certain differentiable manifolds. The second chapter deals with covariant vectors, in particular, with tangent vectors, vector fields, Lie brackets, Frobenius' theorem, and fibre bundles. In the next section tensors are introduced, and the Lie derivative is defined. Chapter 4 is about exterior differential forms. Following this, a sketch of Riemannian geometry is given, calling attention to Cartan methods with Chevalley concepts.

While the material so far presented is essentially a survey of differential geometry from a modern viewpoint, the second part of the lectures is devoted to an introduction to algebraic topology. Chapter 6 introduces the reader to cohomology, various homotopy theorems, and to cohomology computations. The last chapter presents suggestions of cellular cohomology and deals briefly with combinatorial topology, relative cohomology, and cohomology of spheres.

Kikkawa, Michihiko 5196

On affinely connected spaces without conjugate points.
J. Sci. Hiroshima Univ. Ser. A-I Math. **28** (1964), 33–38.

Let M^n be a C^∞ manifold with affine connexion ∇. A Jacobi equation for a vector field along a geodesic is derived from a geodesic deviation, allowing definitions of Jacobi fields and conjugate points as usual. If $n = 2$, ∇ is symmetric, and the Ricci curvature of a vector is always positive semi-definite (or negative semi-definite if one wants the Ricci curvature on a sphere to be positive), then there are no conjugate points. An example shows there exists a non-flat symmetric connexion on the 2-torus with no conjugate points, a situation shown to be impossible in the Riemannian case by E. Hopf [Proc. Nat. Acad. Sci. U.S.A. **34** (1948), 47–51; MR **9**, 378].

Cenkl, Bohumil 5197

Les variétés de König généralisées. (Russian summary)
Czechoslovak Math. J. **14** (89) (1964), 1–21.

The author considers a differentiable manifold X_n and associates a projective space $P_N(\xi)$ and a distinguished subspace $P_p(\xi)$ of $P_N(\xi)$ with each point ξ of X_n. The subscripts n, N, p denote dimension. The spaces $P_N(\xi)$ are projectively related along differentiable curves by means of a connection, and the resulting structure is called a generalised König manifold with projective connection. The paper is mainly concerned with the development of a tensor calculus and curvature theory for this structure.

Cenkl, Bohumil 5198

L'équation de structure d'un espace à connexion projective. (Russian summary)
Czechoslovak Math. J. **14** (89) (1964), 79–94.

The first part of this paper is a summary of the theory of a generalised König manifold with projective connection due to the author [#5197 above]. With the notation of that

paper (or the review) the author considers the particular case $n=2$, $N=3$, $p=0$, and introduces geometrical notions generalising those of the classical projective differential geometry of surfaces. The integrability conditions for the structure equations are interpreted in terms of these notions. *F. Brickell* (Southampton)

Švec, Alois 5199

Au sujet de la définition des variétés de König. (Russian summary)

Czechoslovak Math. J. **14** (**89**) (1964), 222–234.

Denote by G^n the general affine group in n variables and by U_r a domain in r-dimensional real number space. The author calls the product $P_n{}^r = U_r \times G^n$ a König manifold and, regarding $P_n{}^r$ as a principal fibre bundle with group G^n, he defines a connection in a standard way using a differential 1-form ω. Now let G^p be the subgroup of G^n leaving invariant a p-plane; then, using the curvature form of the connection, a 2-form is defined with values in the quotient space of the Lie algebras of G^n and G^p. This form is called the torsion form of the König manifold $P^r_{p,n}$. There is a natural injection of $U_r \times G^p$ into $P_n{}^r$ and, because G^n/G^p is reductive for $p=0$, the form ω can be used to define a connection form on $U_r \times G^0$. The curvature form of this connection is called the curvature form of $P^r_{0,n}$. The author calculates the various curvature and torsion forms in terms of local coordinates.

Levine, Jack 5200

Liouville spaces admitting groups of motions.

Tensor (*N.S.*) **15** (1964), 243–257.

Defining a Liouville space, L_n, as a Riemannian space whose fundamental form is expressible as

$$\phi = (X_1+X_2+\cdots+X_n)\sum_{i=1}^{n} e_i(dx^i)^2,$$

where $X_i = X_i(x^i)$ is a function of the coordinate x^i only and $e_i = \pm 1$, the author determines all L_n, for $n \geqq 3$, admitting groups of motions, and obtains the complete group of motions in each case. *M. C. Chaki* (Calcutta)

Raghunathan, M. S. 5201

Addendum to "Deformations of linear connections and Riemannian manifolds".

J. Math. Mech. **13** (1964), 1043–1045.

A generalization of the results (Theorems 8.1, 9.1, and 9.2) and a correction to the proof of Proposition 10.1 in a previous paper [same J. **13** (1964), 97–123; MR **28** #4484]. The generalization consists in considering a variation of a tensor field along with the connection and gives a unified treatment of the deformation of Riemannian metrics and linear connections treated separately in the previous paper.

K. Nomizu (Providence, R.I.)

Roter, W. 5202

Some remarks on second order recurrent spaces.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 207–211.

A non-flat riemannian space with positive definite metric is recurrent if the components of the curvature tensor satisfy $R_{hijk,l} = c_l R_{hijk}$. The space is 2-recurrent if $R_{hijk,lm} = a_{lm} R_{hijk}$ for some a_{lm}. Lichnerowicz proved [Proc. Internat. Congr. Mathematicians (Cambridge, Mass., 1950) Vol. 2, pp. 216–223, Amer. Math. Soc., Providence, R.I., 1952; MR 13, 492] that a compact 2-recurrent space with scalar curvature $R \neq 0$ is either Cartan-symmetric or else recurrent. The author claims to prove this result without making the assumptions of compactness or that $R \neq 0$. Compactness is certainly unnecessary, but in his proof the author makes use of a vector which is defined to be the gradient of the logarithm of $|R|$, and here surely the assumption $R \neq 0$ is implicitly made.

Necessary and sufficient conditions are found for a space to be 2-Ricci-recurrent, i.e., the Ricci tensor satisfies $R_{ij,lm} = a_{lm} R_{ij}$. *T. J. Willmore* (Liverpool)

Efimov, N. V. 5203

Generation of singularities on surfaces of negative curvature. (Russian)

Mat. Sb. (*N.S.*) **64** (**106**) (1964), 286–320.

The author gives a detailed proof for the old conjecture that a complete surface F in E^3 with Gauss curvature $K \leqq c < 0$ and without singularities does not exist. The result was announced in Dokl. Akad. Nauk SSSR **150** (1963), 1206–1209 [MR **27** #694]; we retain the notation of the latter review. The idea of the proof and a fundamental lemma are discussed, and it is stated that further details are necessary to see how the lemma yields the result.

The lemma appears in the present paper essentially as Lemma A; the missing steps are provided by Lemmas B and C. The first states that the boundary of the spherical image F_1 of F cannot be anywhere concave, i.e., does not possess a subarc whose concave side lies (locally) in F_1. Concavity is to be understood in a certain generalized sense. Lemma C shows that a domain on the unit sphere, which is nowhere concave in this sense, is convex. The above review shows why this yields the theorem.

Šor, L. A. 5204

On the flexibility of convex polygons with a slit. (Russian)

Ukrain. Mat. Ž. **16** (1964), 513–520.

Let $\bar{P}$ be a closed convex polyhedron or a complete unbounded polyhedron with total curvature 2π. Let P originate from $\bar{P}$ by cutting $\bar{P}$, in the same sense as in classical complex variable theory, along a simple polygon L which may be unbounded if $\bar{P}$ is, but does not decompose $\bar{P}$. P is monotypic if no convex polyhedron intrinsically isometric, but not congruent, to P exists. P is bendable if it can be imbedded in a continuous family of intrinsically isometric convex polyhedra which are not all congruent.

A. D. Alexandrov proved long ago that P is monotypic if L is bounded and does not contain a vertex. It is shown here that this remains true when L contains at most one vertex. If the endpoints of L are vertices of $\bar{P}$, then P is, in general, bendable. The same is true for unbounded L beginning at a vertex and containing no other vertex. But examples are also given of such P which are monotypic.

H. Busemann (Los Angeles, Calif.)

Avez, André 5205

Essais de géométrie riemannienne hyperbolique globale. Applications à la relativité générale.

Ann. Inst. Fourier (*Grenoble*) **13** (1963), *fasc.* 2, 105–190.

This work is primarily concerned with the two problems: (1) Is a complete riemannian 4-manifold with hyperbolic metric and zero Ricci curvature locally euclidean? (2) Classify those complete riemannian 4-manifolds with hyperbolic metric and elliptic Ricci tensor. The essential difficulty of solving these problems is due to the absence of global theorems on riemannian manifolds with non-elliptic signature.

The first chapter describes a method for transforming the problem to an analogous problem involving an elliptic metric. This method shows that Mach's principle remains valid for a stationary model of space-time without any additional assumption other than compactness. Moreover, a stationary and compact model of the universe is constructed without using the cosmological constant, thus showing that the existence of global sections of space is essential to the theorem of Aufenkamp.

The second chapter examines a "temporal" analogue of the Hopf-Rinow theorem with a hyperbolic signature. An argument analogous to that used by Myers shows that every complete space-time whose density of matter exceeds a positive number is closed and homotopic to zero in the time. By means of theorems of Nash and Morrey it is proved that on every periodic closed space-time there is a global section of the space which is maximal in the sense of the calculus of variations, and from this is deduced the validity of Mach's principle for closed periodic space-times.

The final chapter attempts to extend to metrics of arbitrary signature the theory of Hodge and de Rham; here the situation differs considerably from the elliptic case, and there are essentially two different types of decomposition in the sense of Hodge. Techniques previously used by Bochner and Lichnerowicz are then applied to the corresponding decompositions. *T. J. Willmore* (Liverpool)

Dautcourt, G. [Dautcourt, Georg] 5206

Zum Anschluss von Lösungen der Einsteinschen Feldgleichungen.

Monatsb. Deutsch. Akad. Wiss. Berlin **5** (1963), 416–420.

The author discusses the nature of the solutions of the algebraic equations relating the discontinuities in the first derivatives of the metric tensor across a hypersurface S with those of the stress energy tensor for space-times satisfying the generalization of the Einstein field equations to the case where such singular hypersurfaces are present. Both the case when the normal to S is time-like and when it is null are considered. In the latter case it is shown that only special material tensors are allowed. The null geodesics whose tangents are the normals to the hypersurface are shown to be the same curves on both sides of the singular null-hypersurface. *A. H. Taub* (Berkeley, Calif.)

Dautcourt, Georg 5207

Über Flächenbelegungen in der allgemeinen Relativitätstheorie.

Math. Nachr. **27** (1963/64), 277–288.

The author considers as given two solutions of the Einstein field equations in vacuum. He raises the question as to whether these can be fitted together across a hypersurface in space-time in such a way that the metric tensor is continuous across this hypersurface but its derivatives need not be. He shows that this problem may be reduced to the problem: When are two metric tensors in a three- or two-dimensional space related by a coordinate transformation? The two-dimensional problem occurs when the hypersurface has a null-vector as a normal vector.

A. H. Taub (Berkeley, Calif.)

Treder, H. 5208

Statische Einstein-Räume mit veränderlicher Signatur.

Monatsb. Deutsch. Akad. Wiss. Berlin **6** (1964), 88–91.

The author gives a canonical form for the metrics of static space-times of signature -2 which satisfy the Einstein vacuum field equations. The space-times in question have a metric tensor whose determinant vanishes on a space-like hypersurface. It is shown that in the neighborhood of this surface this canonical form may be used to define a Riemannian space for which the Ricci tensor vanishes and for which the metric tensor has signature of -2 on one side of the hypersurface, -3 on the hypersurface, and -4 on the other side of the hypersurface. On the hypersurface the determinant of the metric tensor vanishes and across it the metric tensor and its first derivatives are continuous. *A. H. Taub* (Berkeley, Calif.)

Franklin, Stanley P. 5212

Quotient topologies from power topologies.

Arch. Math. **15** (1964), 341–342.

The author shows that if R is an equivalence relation on a topological space X, then the quotient topology on X/R is the restriction to X/R of either of two topologies T_1 and T_2, which can be defined on the collection of all non-empty subsets of X. It should be noted that both T_1 and T_2 are defined in terms of R.

E. Michael (Seattle, Wash.)

Ikenaga, Shogo 5213

Product of minimal topological spaces.

Proc. Japan Acad. **40** (1964), 329–331.

Solving a problem of Berri [Trans. Amer. Math. Soc. **108** (1963), 97–105; MR **27** #711], the author shows that every product of minimal Hausdorff spaces is minimal Hausdorff. The corresponding question for regular spaces remains open; the author shows that the answer is affirmative if there is only one non-compact factor.

J. R. Isbell (New Orleans, La.)

Pickert, Günter 5214

Nachbarschaftsfilter und Verbandshalbgruppen.

Arch. Math. **13** (1962), 151–159.

The author obtains theorems on representations of filters and neighborhood filters. An example of the former is the following. Each filter $\mathfrak{F}$ in a set M is of the form (1) $\mathfrak{F} = \{K_\alpha | \alpha \in \mathbf{M}_*\}$ with (2) $K_\alpha = \{x | d(x) \leq \alpha\}$, where $\mathbf{M}$ is a completely distributive lattice with order relation $\geq$, $\mathbf{M}_0$ is an ideal in $\mathbf{M}$ (l.u.b.'s in $\mathbf{M}_0$ are the same as in $\mathbf{M}_*$) and d is a function from M to $\mathbf{M}$ with the following property: (3) To each $\alpha \in \mathbf{M}_0$ there is $x \in M$ such that $d(x) \leq \alpha$. Conversely, if $\mathbf{M}$ is a set with a transitive relation $\leq$ and $\mathbf{M}_0 \subset \mathbf{M}$ is directed downward and $\mathfrak{F}$ is defined by (1) and (2) with (3) holding, then $\mathfrak{F}$ is a filter base.

A neighborhood filter in a space R is given in terms of a "distance" function from $R \times R$ into a complete lattice-semigroup. The complete statement of this theorem is quite long. *R. W. Bagley* (Coral Gables, Fla.)

Bose Majumder, N. C. 5215

A study of certain properties of the Cantor set and of an (SD) set.

Bull. Calcutta Math. Soc. **54** (1962), 8–20.

The author proves the following theorems. Any point in the unit cell in the p-dimensional Euclidean space is the center mean position of at least $(p+1)^{p-1}$ sets, each of $(p+1)$ points, all belonging to the product set of p Cantor sets defined in the unit cell.

Theorem: A necessary and sufficient condition that a linear set E whose elements are distributed symmetrically in the unit interval be a set whose distance set fills up an interval of length equal to the diameter of the set is that any point in the unit interval is the midpoint of at least one pair of elements of E. A similar theorem is given for p-dimensional sets. These results are related to results of Randolph [Bull. Amer. Math. Soc. **46** (1940), 888; J. London Math. Soc. **16** (1941), 38–42; MR **3**, 226]. The methods are elementary. *L. K. Barrett* (Knoxville, Tenn.)

Unimodular weight functions and a problem of P. S. Aleksandrov and P. S. Urysohn in the theory of bicompacta. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1260–1263.

The principal results are that if there exists a counterexample to the Aleksandrov-Urysohn conjecture that first countable bicompacta have at most c points, it cannot be a continuous image of either a product of bicompacta of weight $\leq c$ or of a bicompact subset of a Σ-product of intervals. *J. R. Isbell* (New Orleans, La.)

Heath, R. W. 5217

Separability and $\aleph_1$-compactness.

Colloq. Math. **12** (1964), 11–14.

A space is said to be $\aleph_1$-compact provided that every uncountable subset of it has a limit point. F. B. Jones has shown [Bull. Amer. Math. Soc. **43** (1937), 671–677] that if $2^{\aleph_0} < 2^{\aleph_1}$, then every separable normal space is $\aleph_1$-compact. The author constructs, under the assumption that $2^{\aleph_0} = 2^{\aleph_1}$, an example of a separable normal T_1-space which is not $\aleph_1$-compact. Two metrization theorems, which generalize some theorems of McAuley and Bing, are also proved: Every separable, strongly complete, regular semi-metric space and every separable Moore space, every open covering of which has a point-countable, open refinement, is metrizable. To prove these theorems the author shows that the spaces of the above classes are $\aleph_1$-compact, and he applies the theorem of F. B. Jones [loc. cit.] which asserts that every $\aleph_1$-compact Moore space is metrizable.

Treybig, L. B. 5218

Concerning continuous images of compact ordered spaces.

Proc. Amer. Math. Soc. **15** (1964), 866–871.

The main result is the following interesting theorem. Let X and Y be two infinite compact Hausdorff spaces and let the direct product $X \times Y$ be the image of a totally ordered compact space L under a continuous mapping $f: L \to X \times Y$. Then both X and Y are metrizable. This extends essentially results of P. Papić and the reviewer who obtained the same conclusion under stronger assumptions: (i) L is connected [Mardešić, Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **15** (1960), 85–89; MR **24** #A535], or (ii) X and Y are locally connected [Mardešić and Papić, ibid. **17** (1962), 3–25; MR **28** #1591]. The

proof is based on a sequence of elementary but delicate arguments. The same result was also obtained independently by A. J. Ward (unpublished).

S. Mardešić (Zagreb)

Duda, R. 5219

On compactification of absolute retracts.

Colloq. Math. **12** (1964), 1–5.

Let L_n be the segment (in the plane) with the ends $(0, 1)$ and $(1/n, 0)$ and let $N = \bigcup_{n=1}^{\infty} L_n$. It is proved that the space N is an AR (absolute retract) for normal spaces, but no compactification N^* of N is an AR for any class τ of T_2-spaces which has the following property: (i) For every space $X \in \tau$ there exists a locally connected space $Z \in \tau$ such that X is a closed subset of Z. From a result of Wojdysławski [Fund. Math. **32** (1939), 184–192] it follows that the class of metric and separable metric spaces satisfies (i).

{The validity of the remark before Lemma 1 is by no means obvious; hence the lemma cannot be considered proved. The same applies to the assertion that the class of normal spaces satisfies (i). Fortunately, a well-known specialized version of Lemma 1 is all that is needed to prove the theorem.}

R. Engelking (Warsaw)

Forge, A. B. 5220

Dimension preserving compactifications allowing extensions of continuous functions.

Duke Math. J. **28** (1961), 625–627.

The well-known Hurewicz compactification theorem [W. Hurewicz, Akad. Wetensch. Amsterdam Proc. Sect. Sci. **30** (1927), 425–430] asserts that for every separable metric space X there exists a compact metric space X^* such that (i) X^* contains X as a dense subset, (ii) $\dim X = \dim X^*$. The author shows that if, in addition, a countable family $\{f_i\}_{i=1}^{\infty}$ of continuous functions from X to the unit interval I is given, then there exists a space X^* which also satisfies (iii) the function f_i can be extended to a continuous function $F_i : X^* \to I$ for $i = 1, 2, \cdots$.

{This result was obtained simultaneously by the reviewer [Fund. Math. **48** (1959/60), 321–324; MR **22** #A1347].}

R. Engelking (Warsaw)

Dolčinov, D. 5221

A unified theory of topological spaces, proximity spaces and uniform spaces. (Russian)

Dokl. Akad. Nauk SSSR **156** (1964), 21–24.

A theory is developed, unifying the theories of topological spaces, proximity spaces and uniform spaces. This theory differs considerably from the methods of Á. Császár [*Fondements de la topologie générale*, Akad. Kiadó, Budapest, 1960; MR **22** #4043; German transl., Akad. Kiadó, Budapest, 1963; MR **26** #6917; second edition (in English), Macmillan, New York, 1963; MR **28** #575], and is closer to the treatment of uniform spaces by A. Weil. Let X be a set, and let $\mathfrak{M}$ be a collection of subsets of X which contains in any case all singletons $\{x\}$, $x \in X$. A generalized topology (g.t.) Σ on X with respect to $\mathfrak{M}$ is defined as a set of mappings of $\mathfrak{M}$ in the power set of X satisfying certain conditions. (If $A \in \mathfrak{M}$ and $U \in \Sigma$, $U(A)$ is to be thought of as a neighbourhood of A.) Now if $\mathfrak{M} = \{\{x\} : x \in X\}$, the g.t.'s with respect to $\mathfrak{M}$ are in a natural one-to-one correspondence with the topologies (in the usual sense) on X. If $\mathfrak{M}$ is the full power set $\{A : A \subset X\}$, the g.t.'s on X with respect to $\mathfrak{M}$ satisfying a certain symmetry condition are in one-to-one correspondence with the proximity relations in X, again in some natural way. Finally, the uniform structures are obtained by uniformizing the conditions in the definition of a g.t. (switching of existential and universal quantifiers).

Okuyama, Akihiro 5222

On metrizability of M-spaces.

Proc. Japan Acad. **40** (1964), 176–179.

K. Morita [Math. Ann. **154** (1964), 365–382; MR **29** #2773] introduced the class of M-spaces, and showed that it contains the class of all spaces topologically complete in the sense of Čech. The author proves that a topological space X is metrizable if and only if it is a paracompact M-space with a G_δ diagonal. {Reviewer's note: This generalizes Theorem 5.5 of J. Ceder [Pacific J. Math. **11** (1961), 105–125; MR **24** #A1707], which asserts that X is completely metrizable if and only if it is a paracompact, topologically complete space with a G_δ diagonal.}

E. Michael (Seattle, Wash.)

Saadaldin, Mohammed Jawad 5223

A generalized Lebesgue covering theorem.

Duke Math. J. **29** (1962), 539–542.

Suppose X is a compact metric space. A sequence G of subsets of X is called a contracting sequence if for each $\varepsilon > 0$ there are only a finite number of elements of G having diameter greater than ε. The following theorem is proved. Suppose $\dim X \geqq n$. There exists an $\varepsilon > 0$ such that if G is a contracting sequence of closed sets covering X with $\operatorname{diam}(g) < \varepsilon$ for each $g \in G$, then there exists a point common to at least $n+1$ elements of G. It is also shown that if $\varepsilon > 0$ there exists a countable closed cover G' of X such that $\operatorname{diam}(g) < \varepsilon$ for each $g \in G'$ and such that no three elements of G have a point in common.

Reátegui C., José 5224

On the topology of manifolds. (Spanish)

Univ. Nac. Ingen. Inst. Mat. Puras Apl. Notas Mat. **1** (1962/63), 35–40.

The author determines conditions under which two topologies on a space, one induced by a given family of mappings and the other by the family of inverse mappings, are in fact identical.

H. R. Gluck (Cambridge, Mass.)

Segal, Jack 5225

Mapping norms and indecomposability.

J. London Math. Soc. **39** (1964), 598–602.

Suppose X and Y are metric spaces and $f : X \to Y$. $N(f) = \operatorname{lub} \{\operatorname{diam}[f^{-1}(y)] : y \in Y\}$. f is a wrapping if for any two subcontinua A and B of X such that $A \cup B = X$, either $f(A) = Y$ or $f(B) = Y$. W is the set of wrappings of X onto itself. The author obtains several results, e.g., Theorem: If X is locally connected, then there exists r such that $0 < r < \infty$ and $N(f) \geqq r$ for every $f \in W$. Theorem: If X is a continuum, then X is indecomposable if and only if no positive constant r exists such that $N(f) \geqq r$ for every $f \in W$.

P. Porcelli (Bloomington, Ind.)

Hofmann, K. H.; Mostert, P. S. 5226

Totally ordered D-class decompositions.

Bull. Amer. Math. Soc. **70** (1964), 765–771.

This paper gives the theorems containing the following one without detailed proof. Let S be a compact semigroup which satisfies: (a) $S^2=S$; (b) The union of all subgroups of S is a subsemigroup; (c) S/D, namely, the natural ordering of the D-classes of S (i.e., $D(x)\leqq D(y)$ if and only if $SxS\subseteq SyS$) is connected and totally ordered. Then (1) the relation D is a congruence, (2) the mapping $S\to S/D$ is a homomorphism, and (3) S/D is an I-semigroup, which means a semigroup on an arc such that one endpoint is an identity of the semigroup and the other is a zero. The converse is also true, that is, (1), (2) and (3) imply (a), (b) and (c). Further, from one additional condition, together with (a), (b) and (c), several properties (besides (1), (2) and (3)) of S are derived. A few corollaries are given as immediate consequences of the main theorem. The proofs of the theorems need Clifford semigroups (i.e., the union of groups) with connecting homomorphisms, the structure of the semigroups over gaps, and the concept of admissible spaces. *T. Tamura* (Davis, Calif.)

Hudson, Sigmund N. 5227

Transformation groups in the theory of topological loops.

Proc. Amer. Math. Soc. **15** (1964), 872–877.

The author continues his studies of topological loops by means of the groups of translates, a technique introduced in his earlier paper [Trans. Amer. Math. Soc. **109** (1963), 181–190; MR **27** #5237]. In this paper, he is concerned with necessary and sufficient conditions for a space to admit a loop structure, particularly with a left-invariant uniform structure. Let G be a topological group acting transitively on a space X and $p\in X$. If the map $\pi:G\to X$ defined by $\pi(g)=g(p)$ is open, G is said to act reasonably on X. A cross-section $\delta:X\to G$ is said to be strongly transitive if $y\in X$, and if $\delta(x)(y)=\delta(x')(y)$, then $x=x'$. The author shows that if G acts reasonably on X and there is a strongly transitive cross-section, then X admits a loop structure with a left-invariant uniformity, but possibly lacking continuity for solutions to the equations $ax=y$, $xa=y$. One additional assumption which will ensure their continuity is the compactness of the isotropy group G_p. If X is locally compact and connected, these three conditions are also necessary, where G is the group of left translates. Several other equivalent conditions are given.

Paalman-de Miranda, Aida Beatrijs 5228

★Topological semigroups.

Academisch Proefschrift ter Verkrijging van de Graad van Doctor in de Wiskunde en Natuurwetenschappen aan de Universiteit van Amsterdam.

Mathematisch Centrum, Amsterdam, 1964. 174 pp.

This dissertation is the longest and most detailed account of the structure of (topological) semigroups extant, and is an excellent exposition of most results involving only set-theoretic topology, elementary measure theory and some parts of transformation groups. It omits those results which require algebraic topology, manifold-theory or relation-theory (e.g., Koch's arc theorem).

Despite these lacunae it is very welcome and will be helpful both to the beginner and as a reference until the appearance of the projected books by Mostert and Hofmann and by Št. Schwarz. The bibliography is fairly complete through 1963 with the exception of papers in Eastern European languages, and the reviewer mentions Gluskin [Itogi Nauki (Algebra. Topology. 1962), pp. 33–58, Akad. Nauk SSSR Inst. Naučn. Informacii, Moscow, 1963; MR **30** #176], which cites 274 papers and fills many gaps.

Among the new results are an exhaustive treatment of compact 0-simple semigroups, a careful analysis of compact interval semigroups satisfying $S^2=S$ (which improves many results in the literature), some other useful improvements and extensions and a few shorter and more perceptive proofs.

The dissertation is meritorious as a scholarly document but no less for its contribution to current research and the reviewer regrets that the complexities of the latter make infeasible a detailed account of what is new.
A. D. Wallace (Gainesville, Fla.)

Selden, John 5229

A note on compact semirings.

Proc. Amer. Math. Soc. **15** (1964), 882–886.

The author defines a topological semiring as a Hausdorff space with two continuous associative operations, one distributing across the other, that is to say, $x(y+z)=xy+xz$ and $(y+z)x=yx+zx$. Let $E[+]$ and $E[\cdot]$ denote, respectively, the additive and multiplicative idempotents. The theorem proved is the following: If S is a compact semiring such that $E[\cdot]S\cup SE[\cdot]=S$, then each additive subgroup is totally disconnected. As a corollary, it follows that a compact connected additive subsemigroup with identity is acyclic and arcwise connected. Another corollary: Let S be an additively commutative semiring such that $SE[\cdot]\cup E[\cdot]S=S$. If $e\in E[+]$, and $H[+]$ denotes the union of the additive subgroups of S, then the sets $E[+]$, $E[+]+S$, $e+S$, $H[+]$ and $e+H[+]$ are arcwise connected. Finally, if S is a compact connected additively simple semiring, then $E[\cdot]\subseteq E[+]$.

A number of examples are given and a question is raised concerning the contractibility of certain additive subsemigroups. *R. P. Hunter* (University Park, Pa.)

Geometric topology of manifolds. (Russian)

Itogi Nauki (Algebra. Topology. 1962), pp. 161–187. *Akad. Nauk SSSR Inst. Naučn. Informacii, Moscow,* 1963.

The author gives a detailed expository account of developments up to 1962. The article is subdivided into sections on topological embeddings, homeomorphisms and mappings, the topology of combinatorial 3-manifolds and other manifolds. There is a bibliography of 244 items.

Michael, E. 5233

Cuts.

Acta Math. **111** (1964), 1–36.

Though some of the results apply more generally, we suppose throughout that all spaces referred to are completely regular. If A is a subset of a space X, we say "A nowhere cuts X" if (i) A is "thin" (has empty interior), (ii) for each $a \in A$ and each neighborhood U of a, $U-A$ is not expressible as $V_1 \cup V_2$, where V_1, V_2 are disjoint and open relative to $U-A$, and where $a \in \mathrm{Cl}(V_1) \cap \mathrm{Cl}(V_2)$ (Cl = closure in X). (If X is locally connected, (ii) is equivalent to saying that each $a \in A$ has arbitrarily small neighborhoods V in X for which $V-A$ is connected.) An "(X, A) cut" consists of a space **X**, a subset **A** of **X** which nowhere cuts **X**, and a (continuous) proper (i.e., closed and compact) light map $p: \mathbf{X} \to X$ which maps $\mathbf{X}-\mathbf{A}$ homeomorphically onto $X-A$, and maps **A** onto A. In simple cases, an (X, A) cut is just the result, intuitively speaking, of cutting X along A (as with scissors and paper). The principal results include the following. Given any thin $A \subset X$, an (X, A) cut exists and is essentially unique. It can be constructed by extending the injection map of $X-A$ in X to $j: \beta(X-A) \to \beta X$; p is then the light factor of a monotone-light factorization of $j|j^{-1}(X)$. If X is separable metric, its (X, A) cut will be (separable) metric if and only if A "nowhere scatters" X in the following sense: for each $a \in A$, and for each neighborhood U of a, if $\mathscr{V}$ is any family of pairwise disjoint sets, open relative to $U-A$, which covers $U-A$, then $\mathscr{V}$ is locally finite (in X) at a. If X is metric and A is thin and nowhere scattering, and if $X-A$ is locally connected, the (X, A) cut is also obtainable by taking **X** to be a suitable subset of the completion of $X-A$ in a suitable metric. If A is a thin sub-polyhedron of a locally finite polyhedron X, one can make **A** a sub-polyhedron of a polyhedron **X**, and p simplicial. If X is paracompact, locally connected and unicoherent, and A is closed, non-empty, thin and connected, and if $X-A$ has n components (where n is finite), then so has **A**. The case in which X is a mapping cylinder with "base" A is considered in detail, and the results are applied to study the following generalization of M. Brown's theory of collared sets [Ann. of Math. (2) **75** (1962), 331–341; MR **24** #A3637]. A thin set $A \subset X$ is said to be "multicollared" in X if **A** is collared in **X**; it is "locally multicollared" if it is covered by open sets U of X such that $U \cap A$ is multicollared in U (or, equivalently, in X). Theorem: If X is metric, every locally multicollared set is multicollared. The paper concludes by comparing the notion of an (X, A) cut with a similar notion due to Fox [*Algebraic geometry and topology*, pp. 243–257, Princeton Univ. Press, Princeton, N.J., 1957; MR **23** #A626] and expressed in terms of "completing a spread". Fox's definition is modified [compare the author, Nederl. Akad. Wetensch. Proc. Ser. A **66** (1963), 629–633; MR **28** #1589] without altering it if $X-A$ is locally connected, to produce what is here called a "Fox (X, A) cut", and it is shown that the (essentially unique) Fox (X, A) cut is imbeddable in the (X, A) cut, and coincides with it under mild conditions (though not in general), and is metrizable if X is metrizable and $X-A$ is locally connected.

There are many subsidiary results concerning proper maps, monotone-light factorizations (in this paper, "monotone" means "quotient (i.e., quasicompact) and monotone"), nowhere cutting and nowhere scattering sets and related notions. Sample results: In a first countable space, nowhere cutting implies nowhere scattering. If $(\mathbf{X}, \mathbf{A}, p)$ is an (X, A) cut, then **A** nowhere scatters **X** if and only if A nowhere scatters X. There is also an application to the Freudenthal compactification [compare Fox, loc. cit.].

{The author has informed the reviewer of the following corrections. In Proposition 2.2, it should be required that h is onto. In Proposition 11.2(b), the map f should be light as well as proper. In Theorem 13.1 it suffices that X/A (instead of X) be unicoherent. There are also a number of misprints, especially in the cross-references; the only seriously misleading misprint detected is in the definition of "nowhere separating", p. 31, which should presumably read "... such that $W-A$ is contained in some $V \in \mathscr{V}$". In the example just before Proposition 10.3, "$<$" should be "$\leqq$".} *A. H. Stone* (Rochester, N.Y.)

Ellis, Robert 5234

Global sections of transformation groups.

Illinois J. Math. 8 (1964), 380–394.

From the author's introduction: "Let (X, R) be a transformation group with phase space X and phase group R, the additive group of real numbers. Suppose further that (X, R) is minimal. Then what can be said about X? Various answers have been given to this question [see, for example, Chu, Proc. Amer. Math. Soc. **13** (1962), 503–508; MR **25** #1553; Chu and Geraghty, Bull. Amer. Math. Soc. **69** (1963), 377–381; MR **26** #4334; Ellis, Michigan Math. J. **10** (1963), 97–104; MR **27** #4217; Schwartzman, Ann. of Math. (2) **66** (1957), 270–284; MR **19**, 568; Proc. Nat. Acad. Sci. U.S.A. **48** (1962), 786–791; MR **25** #1543]. Schwartzman [loc. cit.; MR **25** #1543] shows that if, in addition, X is compact, locally pathwise connected, and if (X, R) admits a global section, then X is the base of a covering space with discrete fibers. This allows him to say something about the homotopy groups of X. In particular, he shows that $\pi_1(X) \neq 0$. Recently, Chu and Geraghty [loc. cit.] showed that if X is compact, locally pathwise connected, and if (X, R) is minimal but not totally minimal, then $\pi_1(X) \neq 0$.

"The first part of this paper is devoted to generalizing the notion of global section. The above results are considered in a more general setting, and the relation between them is studied. They are generalized to the case where R is replaced by any topological group whose underlying space is R^n.

"The second part of the paper is concerned with the following problem. Suppose X is a manifold which is minimal under R; need X be orientable? This question is answered in the negative by exhibiting an action of R on the cartesian product X of the torus with the Klein bottle such that (X, R) is minimal. The flow is constructed by first producing a homeomorphism f of $S^1 \times K$ (the circle cross

the Klein bottle) such that $S^1 \times K$ is minimal under the resulting discrete flow, and then R is allowed to act on $(S^1 \times K \times I)/f$ in the standard way; here I is the unit interval and $(S^1 \times K \times I)/f$ is obtained from $S^1 \times K \times I$ by identifying $(z, 0)$ with $(f(z), 1)$ $(z \in S^1 \times K)$. Since f turns out to be isotopic to the identity, the resulting space is homeomorphic to the cartesian product of the torus with the Klein bottle. This flow may be lifted to a flow on the four-torus, T^4. From a result of Auslander and Hahn [Bull. Amer. Math. Soc. **68** (1962), 614–615; MR **25** #4037], this flow does not come from a one-parameter subgroup of T^4." *Deane Montgomery* (Princeton, N.J.)

The four-color problem. (Dutch)

Euclides (*Groningen*) **39** (1963/64), 193–199.

This is an introductory article of a very elementary sort. Kempe chains are introduced, and a few simple cases of reducible maps are discussed. It is shown that all maps with 14 or fewer countries are 4-colorable. Mention is made of the recent theorem by the author and de Groot [Nieuw Arch. Wisk. (3) **11** (1963), 10–18; MR **26** #5561] that every map in which every country has at most five neighbors is 4-colorable. *G. Sabidussi* (Hamilton, Ont.)

Corradi, K. A. 5237

A note on finite graphs.

Acta Sci. Math. (*Szeged*) **25** (1964), 169–171.

The author proves the following. "Let G be a finite graph. Suppose that A, B, and C are independent complete subgraphs of G such that every vertex of G belongs to exactly one of them. Suppose that the number of vertices in A, B, and C is $v(A) = a$, $v(B) = b$, and $v(C) = c$, respectively; further, that the inequality $c \geqq a \geqq b$ holds. If the number of edges connecting a vertex of C with a vertex of $A \cup B$ is at least $(a+b)c - 2b + 1$, then there exist two subgraphs D and E in G, both complete, having no vertex in common, such that $v(D) = c$, $v(E) \geqq a + 1$." An example shows that the theorem cannot be improved by a reduction of the number $(a+b)c - 2b + 1$.

Adem, José 5243

On secondary cohomology operations. (Spanish)

Bol. Soc. Mat. Mexicana (2) **7** (1962), 95–110.

The author describes and applies a way of representing by functional cohomology operations a secondary cohomology operation Φ, associated with a relation of degree r: $\sum \alpha_k\beta_k = 0$ (written for brevity $\alpha\beta = 0$) in the Steenrod algebra on Z_p ($p \geq 2$). For $v \in H^q(X; Z_p)$ with $\beta_k(v) = 0$, take the map $f: X \to K = K(\pi, q)$ of the space X into the Eilenberg-MacLane space $K(\pi, q)$ such that $f^*(\gamma) = v$ (where γ is the fundamental class of K). Then, by a formula similar to the second formula of Peterson and Stein [Amer. J. Math. **81** (1959), 281–305; MR **23** #A1366], $\Phi(v) = (-1)^{r+1}\alpha_f\beta(\gamma)$, modulo a certain subgroup. However, the total indeterminacy here is, in general, larger than for the usual expression of Φ as a secondary operation. But conditions can be given in order that $f^*H^{q+r}(K) = 0$, which ensures that the additional indeterminacy vanishes; the functional representation is used to assure that some secondary cohomology operations vanish on low-dimensional classes. This is applied to some of the secondary operations that were introduced by Adams [Ann. of Math. (2) **72** (1960), 20–104; MR **25** #4530]. A Cartan formula is given for functional operations, and yields a product formula, by which the action of the secondary operation Φ on the cup product $u \cup v$ equals $\Phi(u) \cup v + (-1)^{ru} u \cup \Phi(v)$ (modulo the suitable indeterminacy), provided u and v satisfy some conditions.

G. Hirsch (Brussels)

Arkowitz, Martin 5244

Commutators and cup products.

Illinois J. Math. **8** (1964), 571–581.

Let j: $A_1 \vee A_2 \to A_1 \times A_2$ be the inclusion. If j is considered to be a fibre map, the fibre is, by definition, $A_1 \flat A_2$, the flat product of A_1 and A_2. Let X be an H'-space. Then the author constructs a flat product $\pi(X, A_1) \times \pi(X, A_2) \to \pi(X, A_1 \flat A_2)$. If $A_i = K(G_i, m_i + 1)$, he constructs a map $\theta: A_1 \flat A_2 \to K(G_1 \otimes G_2, m_1 + m_2 + 1)$. Hence, composition gives a cohomology flat product

$$\langle\ ,\ \rangle: H^{m_1+1}(X; G_1) \times H^{m_2+1}(X; G_2) \to H^{m_1+m_2+1}(X; G_1 \otimes G_2)$$

when X is an H'-space. Let $\tau: \pi(\Sigma Y, Z) \to \pi(Y, \Omega Z)$ be the adjoint isomorphism. Then the author's main theorem is as follows. Let $\alpha_i \in H^{m_i+1}(\Sigma Y; G_i)$. Then $\tau\langle\alpha_1, \alpha_2\rangle = \tau\alpha_1 \cup \tau\alpha_2$. He uses this theorem to prove corollaries concerning $\cup$-long and conil and a modified distributive law.

Maunder, C. R. F. 5245

On the differentials in the Adams spectral sequence.

Proc. Cambridge Philos. Soc. **60** (1964), 409–420.

The Adams spectral sequence [J. F. Adams, Comment. Math. Helv. **32** (1958), 180–214; MR **20** #2711] is a spectral sequence with initial term $\mathrm{Ext}_A(H^*(X, Z_p), H^*(Y, Z_p))$, where A is the Steenrod algebra, and which converges to the stable track group $[Y, X]$. In general, little is known about the differentials in this spectral sequence. The author shows how one may define a set of stable, higher-order cohomology operations, whose action gives the action of the differentials. As an application in the case of stable homotopy groups of spheres, he gives a proof of the formula $d_2(h_m) = h_0h_{m-1}^2$ ($m \geq 4$), which is originally due to Liulevicius.

Unions and intersections in homotopy theory.

Comment. Math. Helv. **38** (1964), 293–307.

In an earlier paper [Math. Ann. **151** (1963), 150–186; MR **27** #3681] the authors defined notions of kernel, coker, union, etc., for categories which are not necessarily abelian. For example, the kernel ideal, ker(f), of a map $f: A \to B$ is the set of all $g: D \to A$ such that $fg = 0$. Ker(f) is principal and is generated by c if $g = uc$ for all $g \in \ker(f)$.

These ideas, together with a definition of homotopy in an abstract category, are combined to give very simple proofs of some results in the homotopy theory of CW-complexes. For example, Lemma 2.6 of the reviewer's paper [Ann. of Math. (2) **75** (1962), 467–484; MR **25** #1551] and the Mayer-Vietoris sequence are obtained in this context.

Iwata, Koichi 5248

On the realizability of Whitehead products.

Tôhoku Math. J. (2) **16** (1964), 203–208.

This paper is devoted to the realizability of quasi-Lie rings (in the sense of Hilton) as Whitehead rings of spaces, i.e., the quasi-Lie ring associated with a space by taking the homotopy groups $\pi_i(X)$ of the space and the Whitehead products $\pi_p(X) \times \pi_q(X) \to X_{p+q-1}(X)$ as the multiplication. This problem has previously been studied by Meyer [Amer. J. Math. **82** (1960), 271–280; MR **26** #6965] and Miyazaki [Tôhoku Math. J. (2) **12** (1960), 1–30; correction, ibid. (2) **12** (1960), 480; MR **22** #5971; errata, MR **22**, p. 2546]. In the present paper the author uses results of Peterson and the reviewer on cohomology operations and their relations with Whitehead products to derive necessary and sufficient conditions for realizability of the following problem: Given three abelian groups π_2, π_3, π_4 such that

$$\mathrm{Ext}(H_5(\pi_2, 2); \pi_4) = 0,$$

find homomorphisms $\pi_2 \times \pi_2 \to \pi_3$ and $\pi_2 \times \pi_3 \to \pi_4$.

The general problem seems as far from solution as is the

analogous problem of realizability of associative, commutative, graded rings as cohomology rings of spaces.

{The proof of the main theorem seems to have a serious gap. The statement on p. 207 that because ${}^1\theta(\iota-x')=0$ we can conclude that $\iota-x'=2x''$ for some $x''\in H^3(F;\pi_3)$ is not justified and seems to the reviewer to be false. Therefore the element $k_0\in H^5(E;\pi_4)$ may not exist and the proof depends crucially on this element.}

Homotopy theory. **(Russian)**

Itogi Nauki (*Algebra. Topology.* 1962), *pp.* 107–133. *Akad. Nauk SSSR Inst. Naučn. Informacii, Moscow,* 1963.

This survey article is based on papers on homotopy theory reviewed in RŽMat. in 1961 and 1962. The sections of the survey are devoted to cohomology operations, duality principles, homology groups and homotopy groups and their computation, the homotopy classification of mappings, simplicial sets, fibre spaces, transformation groups, and H-spaces. There is a bibliography of 241 items.

Atiyah, M. F.; Bott, R.; Shapiro, A. 5250

Clifford modules.

Topology **3** (1964), *suppl.* 1, 3–38.

According to the authors, "the purpose of the paper is to undertake a detailed investigation of the role of Clifford algebras and spinors in the KO-theory of real vector bundles. On the one hand the use of Clifford algebras throws considerable light on the periodicity theorem for the stable orthogonal group. On the other hand the use of spinors seems essential in some of the finer points of the KO-theory which centre round the Thom isomorphism".

Part I is entirely algebraic, and studies Clifford algebras and spinor groups. The material is essentially known, but its presentation is improved. In particular, the authors emphasise the grading (over Z_2) of the Clifford algebra. They can thus write formulae which involve signs given by the standard "anticommutative law" of algebraic topology; in this way the algebra becomes simpler and more natural. A feature of this approach is that the spinor group with two pathwise-components, which is a double covering of $O(k)$, arises as naturally as the spinor group with one pathwise-component, which is a double covering of $SO(k)$. § 4 gives the structure of the Clifford algebras, and §§ 5, 6 discuss their representation theory.

In Part II the authors give a complete treatment of the "difference bundle construction" in K-theory. This includes a Grothendieck-type construction for the relative groups $K(X, Y)$ (9.1) and a discussion of the products in these groups (10.3, 10.4).

In Part III, §§ 11, 12, the authors set up the Thom isomorphism φ for real K-theory. Their construction of φ is clearly good; in particular, if φ is applied in a Whitney sum bundle, it satisfies a product formula. [Since it is one of the main objects of the paper to prove this formula, it is remarkable that the formula is not formally stated; the reader is left to deduce it from 11.3.] However, the authors seem less satisfied with their proof that φ is an isomorphism. In fact, the crucial step (11.5) amounts to case-by-case checking, using the results of R. Bott [Bull. Soc. Math. France **87** (1959), 293–310; MR **22** #A3577], that φ has the correct effect when the base-space is a point.

An alternative construction of the Thom isomorphism has been given in R. Bott [Bull. Amer. Math. Soc. **68** (1962), 395–400; MR **27** #2966]. This approach is convenient for computing the effect of representations, but does not lead to the product formula. It is therefore desirable to prove that the two constructions coincide. This is done in §§ 13, 14, by studying the sphere as a coset space of the spinor group.

{The reviewer remarks that the work of D. W. Anderson on $KO(BG)$ apparently yields a third approach to the Thom isomorphism for real K-theory.}

Having shown in the course of the work that Clifford algebras are related to the Bott periodicity theorem, the paper ends (§ 15) by showing that they are related to certain questions about vector bundles over stunted projective spaces and about vector-fields on spheres.

Although the main interest of the paper lies in real K-theory, it is a feature of the method that the real and complex cases can be treated in parallel throughout.

Differential topology. **(Russian)**

Itogi Nauki (*Algebra. Topology.* 1962), *pp.* 134–160. *Akad. Nauk SSSR Inst. Naučn. Informacii, Moscow,* 1963.

The author gives a detailed expository account of recent developments in differential topology, mainly between 1960 and 1962. The article is subdivided into sections on homotopy groups of spheres, the Hopf invariant and the Steenrod algebra, Thom spaces and cobordism, homotopy properties of the classical Lie groups, immersions and regular mappings of smooth manifolds, critical-point theory and the generalized Poincaré conjecture, Mazur's theorem and the "Hauptvermutung", Milnor spheres, the smoothing problem for combinatorial manifolds, the diffeomorphism problem for simply connected manifolds, and other questions. There is a bibliography of 295 items.

Novikov, S. P. 5252

Foliations of co-dimension 1. **(Russian)**

Dokl. Akad. Nauk SSSR **157** (1964), 788–790.

In this paper, the author generalizes his previous work [same Dokl. **155** (1964), 1010–1013; MR **29** #2821] so as to give more information about oriented smooth foliations of codimension one of three manifolds, as well as some information in higher dimensions. His tools are the notion of component, introduced in the preceding note, and the notion of limiting epimorphism. Let $N_j(A)$, $j=1, 2$, be the set of classes α in the fundamental group of the leaf A such that the corresponding holonomy element (which belongs to the group of germs of orientation-preserving diffeomorphisms of the line leaving the origin fixed) is the identity on the positive [negative] side of the origin. If $\alpha\in N_j(A)$ or $\alpha\in\pi_k(A)$, $k>1$, then α may be pushed off to any nearby leaf on the appropriate side. The limiting epimorphism is the quotient map of which the kernel consists of all α which are contractible in all nearby leaves.

Theorem: If one of the following conditions is satisfied:

(a) there is a closed transversal, homotopic to zero in the manifold; (b) for some leaf A, $\pi_1(A) \to \pi_1(M)$ is not one-one; (c) $\pi_2(M) \neq 0$, but for every leaf A, $\pi_2(A) = 0$, then there is a leaf A_0 and a j such that the limiting epimorphism defined on $N_j(A_0)$ is not one-one.

If M is three-dimensional, this implies that if a foliation is analytic or has no Reeb component, either $M = S^2 \times S^1$, $M = S^2 \times I$, or the universal covering is contractible. On the other hand, an unpublished result of Zieschang is quoted, according to which every closed oriented three-manifold can be foliated.

Details of the proofs are not given. Nonetheless, it is safe to say that the methods introduced here will have far-reaching consequences.

Conner, P. E.; Floyd, E. E. 5253

The SU-bordism theory.

Bull. Amer. Math. Soc. **70** (1964), 670–675.

For each family of classical groups (O, SO, Spin, U, SU, etc.) one can construct the cobordism groups of Thom (in the notation of the reviewer and the authors, these are called bordism groups of a point). For O, SO, U these groups have been explicitly determined. In particular, it has been shown that the SO-bordism groups of a point contain no odd torsion and no elements of order 4. In the present work the authors show that the same is true for the SU-bordism groups of a point. They remark that Lashof and Rothenberg have established this result independently.

The method of dealing with SO is to compare it with O. The reviewer showed [Proc. Cambridge Philos. Soc. **57** (1961), 200–208; MR **23** #A4150] how, using real projective space, one could obtain certain exact sequences connecting the SO- and O-bordism groups. The method of the authors is to derive analogous exact sequences connecting SU- and U-bordism using complex projective space. The first Stiefel-Whitney class is replaced by the first Chern class and dimensions get doubled. Thus the authors get the following exact sequence

$$\Gamma_k(X, A) \to \mathrm{U}_k(X, A) \to \Gamma_{k-2}(X, A) \oplus \mathrm{U}_{k-4}(X, A),$$

where (X, A) is a finite CW-pair, U_k denote the U-bordism groups and Γ_k denote the SU-bordism groups.

Graver, Jack E. 5254

An analytic triangulation of an arbitrary real analytic variety.

J. Math. Mech. **13** (1964), 1021–1036.

A local analytic variety is a subset V of an open set $U \subset E^n$, where V consists of the common zeros of finitely many real power series convergent in U. An analytic variety $V \subset E^n$ is characterized by the property that each $p \in V$ has a neighborhood $U_p \subset E^n$ on which $V \cap U_p$ is a local analytic variety. A triangulation $\tau: K \to S$ of a set $S \subset E^n$ is analytic if $\tau|s$ is analytic with analytic inverse for each open simplex s of K. The main theorem is that an open set $O \subset E^n$ containing finitely many analytic varieties $V_1, \cdots, V_n$ closed in O can be analytically triangulated so that each V_i is a subcomplex. The work appears to be independent of efforts by others who have investigated analytic triangulations.

Adem, José; Gitler, Samuel 5255

Secondary characteristic classes and the immersion problem.

Bol. Soc. Mat. Mexicana (2) **8** (1963), 53–78.

Let $\xi = (E, B, \pi)$ be an n-plane bundle over B and assume certain Stiefel-Whitney classes of ξ vanish. Then one may define certain secondary cohomology operations Φ on the Thom class $U \in H^n(E, E_0)$. These give rise to secondary characteristic classes $\xi^*(\Phi)$ analogous to the definition of the Stiefel-Whitney classes. These characteristic classes are studied more carefully for the tangent bundle and the normal bundle to a manifold. Next, the authors study some particular secondary characteristic operations Φ_{2j} in complex projective spaces. Φ_{2j} is the operation associated to the relation $(Sq^2Sq^1)Sq^{4k} + Sq^{4k+2}Sq^1 = 0$ if $2j = 4k+2$ or $(Sq^2Sq^1)Sq^{4k-2} + Sq^{4k}Sq^1 + Sq^1Sq^{4k} = 0$ if $2j = 4k$. For example, they prove that $\Phi_{2(a+b-c)}(w^{(2h+1)a-b-c}) = hw^{2(ha+a-c)}$, where $w \in H^2(CP^\infty)$ is the generator, $a = 2^r$, $b = 2^s$, $c = 2^t$ and $r > s \geq t \geq 0$ and $h > 0$. They also prove a theorem which shows that $\Phi_{2j}(u) = 0$ for dimensional reasons under certain hypotheses. Putting all this together, they prove the following geometric result. CP^n does not immerse in R^{4n-5} if $n = 2^r + 2^s$ and $r > s \geq 0$. In order to prove theorems about real projective spaces, the authors study "multiple" secondary cohomology operations. In this case, their geometric result is the following theorem. RP^n does not immerse in R^{2n-9} if $n = 4k+3$ and $k = 2^r + 2^s$ with $r > s \geq 0$.

Brieskorn, Egbert 5257

Ein Satz über die komplexen Quadriken.

Math. Ann. **155** (1964), 184–193.

A theorem of Hirzebruch and Kodaira [J. Math. Pures Appl. (9) **36** (1957), 201–216; MR **19**, 1077] states the following. Let X be a Kähler manifold of dimension n which is diffeomorphic to complex projective space P_n. Then: (i) if n is odd, X is biholomorphically equivalent to P_n; (ii) if n is even, $c_1 = \pm(n+1)g$ (g = generator of $H_2(P_n, \mathbf{Z})$, c_1 = first Chern class), and if $c_1 = (n+1)g$, then X is biholomorphically equivalent to P_n. The purpose of the present paper is to prove the same statement with Q_n, the complex n-quadric, replacing P_n. Here one must make the exception $n \neq 2$ since $Q_2 = P_1 \times P_1$ carries infinitely many inequivalent Kähler structures (these are the Hirzebruch surfaces [cf. Hirzebruch, Math. Ann. **124** (1951), 77–86; MR **13**, 574]). The proof is similar to the proof of the aforementioned Hirzebruch-Kodaira theorem; the assumption $n > 2$ comes about in order to make a calculation from the general Riemann-Roch theorem. In fact, for $n > 2$, $H_2(X, \mathbf{Z}) \simeq \mathbf{Z}$ with generator g and $c(Q_n)(1+2g) = (1+g)^{n+2}$; for $n = 2$, $H_2(X, \mathbf{Z}) \simeq \mathbf{Z} \oplus \mathbf{Z}$, and this forces the assumption $n > 2$.

Phillip A. Griffiths (Berkeley, Calif.)

Dolbeault, Pierre 5258

Une généralisation de la notion de diviseur.

Atti Convegno Internaz. Geometria Algebrica (Torino, 1961), *pp.* 125–150. *Rattero, Turin,* 1962.

Il n'y a pas en général assez de diviseurs sur une variété analytique complexe pour assurer l'extension à ces variétés du théorème de Lefschetz et Hodge: "Pour qu'une classe de cohomologie entière de la variété algébrique projective complexe V, sans singularité, soit la classe de cohomologie d'un diviseur, il faut et il suffit que son image dans $H^2(V, C)$ par l'homomorphisme induit par l'inclusion $Z \subset C$, appartienne à $H^{1,1}(V, C)$".

L'auteur établit un théorème analogue sur une variété analytique complexe quelconque V en utilisant la variété analytique réelle sous-jacente V_r.

Soient respectivement $\mathscr{M}$, $\mathscr{M}_r$, $\mathscr{C}^*$, $\mathscr{F}^*$ les faisceaux de groupes multiplicatifs de germes de fonctions à valeurs complexes qui sont méromorphes sur V, méromorphes sur V_r, holomorphes non nulles sur V, holomorphes non nulles sur V_r. Un "pseudodiviseur" est une section de $\mathscr{M}_r/\mathscr{F}^*$. C'est un "pseudodiviseur spécial" s'il est l'image d'une section de $\mathscr{M}_r/\mathscr{C}^*$ par l'application: $\mathscr{M}_r/\mathscr{C}^* \to \mathscr{M}_r/\mathscr{F}^*$. Le groupe des diviseurs est un sous-groupe du groupe des pseudodiviseurs spéciaux.

On a alors la proposition suivante: tout élément de $H^2(V, Z)$ est la classe de cohomologie d'un pseudodiviseur tandis que la condition nécessaire et suffisante pour qu'un tel élément soit la classe d'un pseudodiviseur spécial est que son image dans $H^2(V, C)$ appartienne à $H^{1,1}(V, C)$. *R. Deheuvels* (Paris)

Fischer, Wolfgang 5259

Zur Deformationstheorie komplex-analytischer Faserbündel.

Schr. Math. Inst. Univ. Münster No. 30 (1964), ii + 49 *pp.*

The author constructs to a given holomorphic principal bundle P_0 over the compact complex manifold X a sheaf $A(P_0)$ whose elements are germs of holomorphic deformations of P_0. $H^1(X, A(P_0))$ turns out to be naturally isomorphic to the set of equivalence classes of local holomorphic deformations of P_0. Denoting by A_k the subsheaf of $A = A(P_0)$ consisting of all germs of order $\geq k$, one gets the short exact sequence of sheaves of groups $0 \to A_{k+1}/A_{k+2} \to A/A_{k+2} \to A/A_{k+1} \to 0$. Since A_{k+1}/A_{k+2} is canonically isomorphic to the sheaf $\mathcal{O}(\mathrm{Ad}\, P_0)$ of germs of holomorphic sections in $\mathrm{Ad}\, P_0$, the associated cohomology sequence permits one to define, for every "infinitesimal deformation of P_0 of order k" $q_k \in H^1(X, A/A_{k+1})$ and for every $l \geq k$, the l-obstruction $c_l(q_k)$ of q_k as the obvious subset of $H^2(X, \mathcal{O}(\mathrm{Ad}\, P_0))$. $c_l(q_k)$ is called trivial if it contains the neutral element of $H^2(X, \mathcal{O}(\mathrm{Ad}\, P_0))$. For principal $\mathrm{GL}(n, \mathbf{C})$ bundles, these obstructions can be given in fairly explicit form. If for the principal $\mathrm{GL}(n, \mathbf{C})$ bundle P_0 the relation $H^2(X, \mathcal{O}(\mathrm{Ad}\, P_0)) = 0$ holds, then every principal bundle P_1 whose defining 1-cocycle is sufficiently close to some defining 1-cocycle of P_0 can be obtained by a holomorphic deformation of P_0; moreover, every element in $H^1(X, \mathcal{O}(\mathrm{Ad}\, P_0))$ is an infinitesimal deformation of P_0. Analogous statements concerning constant principal $\mathrm{GL}(n, \mathbf{C})$ bundles are proved. Finally it is shown that, given the principal $\mathrm{GL}(n, \mathbf{C})$ bundle P_0 satisfying $H^1(X, \mathcal{O}(\mathrm{Ad}\, P_0)) = 0$, every other principal bundle P_1 whose defining 1-cocycle is sufficiently close to some defining 1-cocycle of P_0 is holomorphically equivalent to P_0. *H. Röhrl* (La Jolla, Calif.)

Hermann, Robert 5260

Convexity and pseudoconvexity for complex manifolds.

J. Math. Mech. **13** (1964), 667–672.

Let X be a complex manifold of dimension $n > 1$, $Z \subset X$ a relatively compact open submanifold defined by $\varphi < 0$, where φ is a real function on X. Let $H = \partial Z$ be the boundary of Z and assume $d\varphi \neq 0$ near H. Then the E. E. Levi form L is an Hermitian form in $n-1$ variables defined by restricting $\partial\bar{\partial}\varphi$ to complex tangent spaces to H. The form L is not an absolute invariant of the complex structure, but the number of positive and negative eigenvalues of L (= signature) is. The subdomain Z is said to be (strongly) pseudo-convex if L is positive definite, and the intuitive connection between ordinary convexity and pseudo-convexity is put in a general setting by the author's main result (Theorem A). Let X have a symmetric affine connexion and let J be the almost-complex structure tensor. Then

$$(1) \qquad L(u, v) = S(u, v) + S(Ju, Jv),$$

where S is the second fundamental form of H in X and u, v are complex tangent vectors to H ($Ju = \sqrt{(-1)}u$, $Jv = \sqrt{(-1)}v$).

It is perhaps worth remarking that the Levi form controls the (analytic) sheaf cohomology of Z in a manner similar to the way in which the second fundamental form controls the ordinary cohomology (compare the integral estimates in J. Kohn [Ann. of Math. (2) **78** (1963), 112–148; MR **27** #2999] and C. Hsiung [Math. Z. **82** (1963), 67–81; MR **27** #2943]). *Phillip A. Griffiths* (Berkeley, Calif.)

Beyond Bertrand's paradox (What is "random choice"?). (Italian summary)

Rend. Sem. Fac. Sci. Univ. Cagliari **34** (1964), 1–4.

The well-known ambiguity of the expression "at random" is emphasized and illustrated. *I. J. Good* (Oxford)

Kappos, Demetrios A. 5263

Strukturtheorie der Räume von Zufallsvariablen.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (Liblice, 1962), *pp.* 359–375. *Publ. House Czech. Acad. Sci., Prague,* 1964.

The author continues his studies [cf. his *Strukturtheorie der Wahrscheinlichkeitsfelder und -Räume*, Springer, Berlin, 1960; MR **22** #9982; errata, MR **22**, p. 2547] on a (predominately algebraic) structural theory of the foundations of probability, which is based on a σ-Boolean ring with unit element (σ-W-field), equipped with a σ-additive strictly positive measure on the Boolean ring (W-field). He now introduces (real-valued) random variables (r.v.) and analyzes their properties within the context of the above structure. Countably-valued r.v. are discussed and related to the author's definition of "experiment". Various convergence modes for sequences of r.v. are investigated and compared. The final result concerns embedding of Banach lattices and is—like the other results of this paper—too involved to summarize in detail within the scope of this review. *F. J. Beutler* (Berkeley, Calif.)

Kellerer, Hans G. 5264

Allgemeine Systeme von Repräsentanten.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **2**, 306–309 (1964).

For each $i \in M = \{1, \cdots, m\}$ let $\bar{K}_i$ and $\underline{K}_i$ be two subsets of $N = \{1, \cdots, n\}$; and let $\underline{z}_i$, $\bar{z}_i$ ($i \in M$) and $\underline{s}_k$, $\bar{s}_k$ ($k \in N$) be integers. By a general representant system for these objects we mean a system of sets $\{K_i\}$ ($i \in M$) for which $\underline{K}_i \subset K_i \subset \bar{K}_i$ ($i \in M$), $\underline{z}_i \leq |K_i| \leq \bar{z}_i$ ($i \in M$), $\underline{s}_k \leq |I_k| \leq \bar{s}_k$ ($k \in N$). (Here $I_k = \{i : k \in K_i\}$ and $|\ |$ denotes cardinality.) Necessary and sufficient conditions for the existence of general representant systems are given, valid under certain extra hypotheses. *J. M. G. Fell* (Seattle, Wash.)

Miles, R. E. 5265

Random polygons determined by random lines in a plane.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 901–907.

The author considers the convex regions formed by a homogeneous Poisson field of random lines in a plane and reports a series of new results. The distributions of the diameters of the in-circles are negative exponential and the distribution of the perimeters, conditional on the number of sides, is a χ^2 distribution. He also obtains the probability that such a region is a triangle and the lower moments and cross moments of the number of sides, the perimeter, and the area. The joint distributions of the orientations of some of the sides under certain conditions are also found. Generalisations are given for lines of finite thickness and anisotropic distributions. Methods of proof are to be given later. *P. A. P. Moran* (Canberra)

Ibramhalilov, I. Š. 5266

On a method of sharpening a bound for parameters. (Russian. Azerbaijani summary)

Akad. Nauk Azerbaĭdžan. SSR Dokl. **20** (1964), *no.* 6, 15–19.

The problem of finding an improved estimate of the value α which satisfies the equation $\sum_{i=1}^{n} \psi(\xi_i; \alpha) = 0$ is studied; here ξ_i, $1 \leq i \leq n$, are independent, identically distributed, random variables with distribution function $F(x; \alpha)$. Under certain regularity conditions concerning the partial derivatives of ψ with respect to α, and assuming the existence of an estimate of the form $\alpha_1^* = \alpha_0 + \eta_n/\sqrt{n}$, where η_n is an asymptotically normal random variable, a consistent and asymptotically normal estimate $\bar{\bar{\alpha}}$ of α is obtained. *R. Theodorescu* (Bucharest)

Čan Ving H'en [Tran Vinh-Hien] 5267

A central limit theorem for stationary processes arising from number-theoretic endomorphisms. (Russian. English summary)

Vestnik Moskov. Univ. Ser. I Mat. Meh. **1963**, *no.* 5, 28–34.

A. Rényi [Acta Math. Acad. Sci. Hungar. **8** (1957), 477–493; MR **20** #3843], among others, has considered the expansion of $x \in (0, 1)$ in the form $x = \varepsilon_0 + f(\varepsilon_1 + f(\varepsilon_2 + \cdots))$, showing this is possible for certain functions f. He has shown, moreover, that for certain f there exists an absolutely continuous measure carried on $(0, 1)$, of total measure 1, whose density is positive and bounded away from 0 and ∞, and such that with respect to the resulting measure space the remainders $r_n(x) = f(\varepsilon_{n+1} + f(\varepsilon_{n+2} + \cdots))$ constitute a stationary sequence of random variables. In this paper it is proved that for suitable functions f and g the limiting distribution of $g(r_1(x)) + \cdots + g(r_n(x))$ is Gaussian. This result had been proved earlier in two special cases by I. A. Ibragimov [Vestnik Leningrad. Univ. **15** (1960), no. 1, 55–69; MR **22** #11428].

D. A. Darling (Ann Arbor, Mich.)

Emel'janov, G. V. 5268

A local limit theorem for density functions. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 3 (40), 59–69.

Let $X_1, X_2, \cdots$ be independent random variables with means zero and let $S_n = X_1 + \cdots + X_n$, $E(S_n^2) = B_n^2$. Supposing that the distribution function of S_n has a density $q_n(x)$ for sufficiently large n, the author investigates under what conditions the expression

$$M_n = \sup_{-\infty < x < \infty} \left| B_n q_n(xB_n) - \frac{e^{-x^2/2}}{\sqrt{(2\pi)}} \right|$$

converges to zero. Assuming no further conditions on the moments of the X_i other than the finiteness of B_n^2, the author proves that $M_n \to 0$ if the usual Lindeberg condition prevails, and other conditions to center and stabilize the X_i. If a moment of order $2 + \delta$, $\delta > 0$, exists for the X_i and a strengthened form of Lyapounov's condition prevails, $M_n = O((\log B_n)^{-\delta/2})$. If moments of order 3 or higher exist, q_n has a Charlier-type expansion in inverse powers of $n^{1/2}$.

Guiasu, Silviu 5269

La répartition asymptotique des sommes aléatoires de variables aléatoires indépendantes non identiquement distribuées.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **34** (1963), 504–510.

The main result of the paper is the following. Let $\{X_n\}$ be a sequence of independent random variables with mean value 0 and finite variances, and suppose that

$$\lim_{n \to +\infty} P\left(\sum_{k=1}^{n} X_k \leq xW_n \right) = F(x)$$

for every point of continuity of $F(x)$, where W_n^2 denotes the variance of the sum $\sum_{k=1}^n X_k$ and $F(x)$ is a distribution function. If $\{N_n\}$ is a sequence of positive integer-valued random variables for which N_n/n converges in probability to a positive discrete random variable λ and if

(1) $W_{[n\lambda]}/W_{N_n}$ converges in probability to 1,

then

$$(2) \qquad \lim_{n\to\infty} P\left(\sum_{k=1}^{N_n} X_k \leq xW_{N_n}\right) = F(x).$$

Here $[n\lambda]$ denotes the integral part of the real number $n\lambda$. Statement (2) has been proved for the case when the X_n are identically distributed (in which case $W_n = D\sqrt{n}$ and (1) is satisfied) by the reviewer [Acta Math. Acad. Sci. Hungar. **9** (1958), 215–228; MR **20** #4623]; this result has been generalized for the case when the positive random variable λ has an arbitrary distribution by J. Mogyoródi [Magyar Tud. Akad. Mat. Kutató Int. Közl. 7 (1962), 409–424; MR **27** #1979] and independently by J. R. Blum, D. L. Hanson and J. I. Rosenblatt [Z. Wahrscheinlichkeitstheorie und Verw. Gebiete 1 (1962/63), 389–393; MR **27** #5283]. *A. Rényi* (Budapest)

Ostrovskiĭ, I. V. 5270

Infinitely divisible laws with unbounded Poisson spectrum. (Russian)

Dokl. Akad. Nauk SSSR **152** (1963), 1301–1304.

Let $\mathscr{L}$ be the class of infinitely divisible laws with the characteristic functions whose logarithms are represented in the form

$$\log \varphi(t) = i\beta t - \gamma t^2 + \sum_{m=-\infty}^{\infty} \lambda_m^{(1)}(e^{i\mu_m t} - 1 - i\mu_m t/(1+\mu_m^2))$$
$$+ \sum_{m=-\infty}^{\infty} \lambda_m^{(2)}(e^{-i\nu_m t} - 1 + i\nu_m t/(1+\nu_m^2)),$$

where β is real, $\gamma \geq 0$, $\lambda_m^{(1)}, \lambda_m^{(2)} \geq 0$, $\mu_m, \nu_m > 0$ $(m = 0, \pm 1, \pm 2, \cdots)$ and

$$\text{(i)} \sum_{m=-\infty}^{\infty} \lambda_m^{(1)}\mu_m^2(1+\mu_m^2)^{-1} + \sum_{m=-\infty}^{\infty} \lambda_m^{(2)}\nu_m^2(1+\nu_m^2)^{-1} < \infty,$$

and (ii) $\mu_{m+1}\mu_m^{-1}$ and $\nu_{m+1}\nu_m^{-1}$ are integers. Such a class $\mathscr{L}$ of laws has been introduced by Ju. V. Linnik [*Decompositions of probability laws* (Russian), Izdat. Leningrad. Univ., Leningrad, 1960; MR **22** #A2900]. The present paper deals primarily with the factorization problem of the law of $\mathscr{L}$. The author obtains the result that if the i.d.l. of $\mathscr{L}$ satisfies $\lambda_m^{(1)} = O(\exp(-\kappa\mu_m^2))$, $\lambda_m^{(2)} = O(\exp(-\kappa\nu_m^2))$ for an arbitrary $\kappa > 0$, and its characteristic function $\varphi(t)$ admits the factorization $\varphi(t) = \varphi_1(t)\varphi_2(t)$, where $\varphi_1(t)$ and $\varphi_2(t)$ are entire functions such that (*) $|\varphi_i(\sigma+i\tau)| \leq |\varphi(i\tau)|$, $-\infty < \sigma, \tau < \infty$, $i = 1, 2$, then $\varphi_1(t)$ and $\varphi_2(t)$ are, up to constant multiples, the characteristic functions of i.d.l. As a matter of fact, the author gives a theorem of more general type. Let $f(t)$ be any entire function of the form $\sum_1^\infty \lambda_p^{(1)}e^{i\xi_p t} + \sum_1^\infty \lambda_p^{(2)}e^{-i\eta_p t} + l(it)$, where $\xi_p, \eta_p > 0$, $\lambda_p^{(1)}, \lambda_p^{(2)} = O(\exp(-\kappa p^2))$ and $l(z)$ is an entire function with certain properties. Let us suppose that $\exp(f(t)) = \varphi_1(t)\varphi_2(t)$, where $\varphi_i(t)$ are entire and satisfy (*), $i = 1, 2$. The author gives the analytic forms of $\log \varphi_i(t)$. The precise statement is not reproduced here. *T. Kawata* (Washington, D.C.)

Révész, P. 5271

On sequences of quasi-equivalent events. I. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **8** (1963), 73–83.

A sequence of events $\{A_n\}$ on a probability space $(\Omega, \mathcal{S}, P)$ is called quasi-equivalent if the ratio

$$P(A_{i_1}\cdots A_{i_k})/P(A_{i_1})\cdots P(A_{i_k})$$

depends only on k and does not depend on the indices $i_1, \cdots, i_k$. The paper extends to quasi-equivalent sequences of events the results of A. Rényi and the author [Publ. Math. Debrecen **10** (1963), 319–325; MR **30** #1543]. Further results, which we now state, are a law of large numbers and a tail σ-field law. Assume $\liminf P(A_n) > 0$. The quasi-density of a quasi-equivalent sequence of events is the Radon-Nikodým derivative of $\mu(B) = \lim_{n\to\infty} P(B/A_n)$ with respect to P. (It is shown that the limit exists; it then follows [e.g., from the Vitali-Hahn-Saks Theorem] that μ is a P-continuous measure.) Theorem: Let $\{A_n\}$ be a quasi-equivalent sequence of events with quasi-density λ and let α_n be the indicator functions of the A_n. Then

$$P\left[\frac{1}{n}\sum_{k=1}^{n} \frac{\alpha_k}{P(A_k)} \to \lambda\right] = 1.$$

Further, the tail σ-field of $\{A_n\}$ coincides (mod P) with the σ-field generated by λ. *L. Sucheston* (Columbus, Ohio)

Szynal, Dominik 5272

On the strong law of large numbers for random variables bounded by sequences of numbers. (Polish and Russian summaries)

Ann. Univ. Mariae Curie-Skłodowska Sect. A **16** (1962), 123–127 (1964).

The author attempts to give necessary and sufficient conditions for the strong law of large numbers for random sequences (X_n) such that there exist numerical sequences (L_n) with (1) $\sum_n P[|X_n| \geq L_n] < \infty$. However, for any sequence (X_n) there exists such a sequence (L_n) so that (1) is not a restriction; the author's theorem is obviously invalid, and the sequence he considers in his Remark 1 provides, in fact, a counterexample to his "theorem". The theorems used by the author are misquoted and misapplied, and confusion permeates the paper.

Delporte, Jean 5273

Prolongement par continuité d'une fonction uniformément continue sur l'ensemble dyadique $\mathscr{D}\times\mathscr{D}$ et construction de fonctions aléatoires de deux variables presque sûrement continues.

C. R. Acad. Sci. Paris **259** (1964), 1471–1474.

The author gives conditions under which a random function of two variables $x(t, s, \omega)$ is almost surely continuous on $[0, 1]\times[0, 1]$. He obtains as a corollary the following generalization of Kolmogorov's well-known result. Let $x(t, s, \omega)$ be a separable random function on $[0, 1]\times[0, 1]$, for which there exists an $r > 0$ such that $|h|$ and $|h'| \leq \delta$ imply $E|x(t+h, s+h') - x(t, s)|^r = O(\varphi(\delta))$, where $\varphi(\delta) = \delta^{2+\epsilon}$ or $\varphi(\delta) = \delta^2|\log \delta|^{-(1+\epsilon)/\beta}$ $(\beta = \inf(1, 1/r))$; then $x(t, s)$ is almost surely continuous on $[0, 1]\times[0, 1]$.

Fristedt, Bert 5274

The behavior of increasing stable processes for both small and large times.

J. Math. Mech. **13** (1964), 849–856.

The author investigates the sample behavior of the increasing stable processes which have no deterministic linear component, that is, right continuous, strictly increasing processes X on the real line with $X(0)=0$ and $E\{e^{-uX(t)}\}=\exp[-\beta 2^{1-\alpha}tu^{\alpha}]=\int_0^{\infty} e^{-ux}f(t,x)\,dx$, where $0<\alpha<1$ and $\beta>0$. The author gives conditions on h under which the events $\{X(t)\leq h(t)$ i.o. as $t\to 0\}$ or $\{X(t)\leq h(t)$ i.o. as $t\to\infty\}$ have probability zero or one. The following is one of his results. Let h be continuous and strictly increasing in a neighborhood of 0 with $h(0)=0$. For fixed α assume $t^{-1/\alpha}h(t)$ is monotone near 0 and consider the following conditions on h: (i) $t^{-1/\alpha}h(t)\to 0$ as $t\to 0$, (ii′c) $\int_0^1 f[t, ch(t)]\,dh(t)<\infty$, where $0<c\leq 1$ and f is given by its Laplace transform above. If conditions (i) and (ii′1) hold, then $P[X(t)\leq h(t)$ i.o. as $t\to 0]=0$, and if either (i) or (ii′c) for some $c<1$ fail to hold, then $P[X(t)\leq h(t)$ i.o. as $t\to 0]=1$. *R. Getoor* (Stanford, Calif.)

Karlin, Samuel 5275

Total positivity, absorption probabilities and applications.

Trans. Amer. Math. Soc. **111** (1964), 33–107.

An account of the beautiful connections between totally positive functions and 1-dimensional stochastic processes with continuous paths. A function $p(a,b)$ defined on a rectangle of $A\times B$ ($A, B=Z^1$ or R^1) is totally positive if for each choice of $n\geq 1$, $a_1\leq\cdots\leq a_n$, and $b_1\leq\cdots\leq b_n$, the determinant of $p(a_i,b_j)$ $(i,j\leq n)$ is non-negative. For totally positive functions of the special form $p(b-a)$, see I. J. Schoenberg [Bull. Amer. Math. Soc. **59** (1953), 199–230; MR **15**, 16] and I. I. Hirschman, Jr. and D. V. Widder [*The convolution transform*, Princeton Univ. Press, Princeton, N.J., 1955; MR **17**, 479].

The connection with stochastic processes, due to the author and J. McGregor [Pacific J. Math. **9** (1959), 1109–1140; MR **22** #5071; ibid. **9** (1959), 1141–1164; MR **22** #5072], comes about as follows. Consider a Markovian motion on a subinterval Q of Z^1 or R^1 with transition probabilities

$$P[x(t)\in db\,|\,x(s)=a]=P_a[x(t-s)\in db]=p_{t-s}(a,b)e(db)\qquad (t>s).$$

Under a mild technical condition $p_t(a,b)$ is totally positive for each $t>0$ if and only if the motion has continuous sample paths (meaning that the particle moves by unit jumps if $Q\subset Z^1$), and in this case the determinant of $p_t(a_i,b_j)$ $(i,j\leq n)$ is the transition density for $n\geq 1$ independent particles starting at $a_1<\cdots<a_n$ to come in time $t>0$ to $b_1<\cdots<b_n$ without crossing. The principal new result of this kind proved here is that the density $q_t(a,b)=\partial P_a[T_b<t]/\partial t$ for the passage time $T_b=\min(t\colon x(t)=b)$ is totally positive as a function of $t>0$ and a $(<b)$ and also as a function of $t>0$ and a $(>b)$.

Only part of the paper deals with total positivity as such. A number of related function classes are defined and studied. Applications to eigendifferential expansions, to the behaviour of ratios of transition probabilities as $t\uparrow+\infty$, to the unimodality of passage time densities and stable laws, etc., are included, together with a large number of instructive examples.

{A misapprehension spoils Theorem 6.3: A 1-dimensional diffusion with "non-negative drift" is simply translation at speed 1 relative to a suitable scale, so that the functions appearing in the statement do not exist.}

Laha, R. G.; Lukacs, Eugene 5276

On identically distributed stochastic integrals.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 467–474. *Publ. House Czech. Acad. Sci., Prague*, 1964.

Let $X(t)$, $t\in[a,b]\subset R$, be a process with independent increments, all moments finite, and mean value and variance functions of bounded variation on $[a,b]$. Form the integrals in quadratic mean $Y=\int_a^b a(t)\,dX(t)$, $Z=\int_a^b b(t)\,dX(t)$, where $a(t)$ and $b(t)$ are continuous in $t\in[a,b]$ with $\max_t|a(t)|\neq\max_t|b(t)|$. The authors prove that Y and Z are identically distributed if and only if $X(t)$ is a Wiener process and $\int_a^b[a(t)]^k\,dt=\int_a^b[b(t)]^k\,dt$ for $k=1$ and 2. Then they establish a similar theorem for $t\in[a,\infty)$. *M. Loève* (Berkeley, Calif.)

Mandl, Petr 5277

Diffusion processes with weakly absorbing boundary. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 283–292.

Let $P(t,x;E)$ be transition probabilities corresponding to a homogeneous diffusion process on $[0,\infty)$. Let the corresponding semigroup of operators $T_tf=\int P(t,x;dy)f(y)$ on the space of continuous functions on $[0,\infty)$ have an infinitesimal generator which is a contraction of $\Omega f=d^2f/dx^2+b(x)\,df/dx$ with respect to a Feller boundary condition

$$(\tau+\varepsilon)f(0)=\tau\int_0^{\infty}f(x)\,dp(x)-\sigma\Omega f(0)+\gamma f'(0)$$

at $x=0$. Here, let $b(x)$ be continuous on $[0,\infty)$, $p(x)$ a distribution function continuous at $x=0$, and τ, σ, and γ non-negative constants with $\max(\tau,\sigma,\gamma)>0$. Let ε be a parameter >0, and $F(t,x;\varepsilon)$ the probability of absorption at 0 by time t starting from x at time 0. The author studies $\lim_{\varepsilon\to 0}F$ in terms of the distribution function

$$\Phi(t,\rho)=\sum_{n=1}^{\infty}(-1)^{n+1}\frac{t^{n\rho}}{\Gamma(n\rho+1)},\qquad 0<\rho\leq 1.$$

He proves four theorems, of which we state the first two.

Let $\Omega f=D_vD_uf$ be Feller's representation; $u(x)=\int_0^x Q(y)^{-1}\,dy$ and $v(x)=\int_0^x Q(y)\,dy$, where $Q(x)=\exp\int_0^x b(s)\,ds$. Theorem 1: If

$$M=\tau\int_0^{\infty}\int_0^{x}(v(\infty)-v(y))\,du(y)\,dp(x)+\gamma v(\infty)+\sigma<\infty,$$

then $\lim_{\varepsilon\to 0}F(tM\varepsilon^{-1},x;\varepsilon)=\Phi(t,1)=1-e^{-t}$.

Let $\alpha(x)$ and $\beta(x)$ be continuous on $[0,\infty)$. Theorem 2: If $\tau\neq 0$ and $b(x)=-B+\beta(x)$, where $0<B<\infty$, if $\int_0^{\infty}e^{(B+\delta)x}|\beta(x)|\,dx<\infty$ for arbitrary $\delta>0$, and if $\int_0^t(1-p(y))\,dy\sim At^{\gamma}$ for some $\gamma>0$, then for $M=A\Gamma(\gamma+1)B^{\gamma-1}$,

$$\lim_{\varepsilon\to 0}F(t[M\varepsilon^{-1}]^{(1-\gamma)^{-1}},x;\varepsilon)=\Phi(t,1-\gamma).$$

J. Chover (Madison, Wis.)

Pitcher, T. S. 5278

Likelihood ratios of Gaussian processes.

Ark. Mat. **4**, 35–44 (1960).

The author considers a real Gaussian stochastic process $x(t)$ on a finite time interval and considers the measure m_f on the set of sample functions as a functional of the mean value function $f(t)$. He shows that if m_f and m_0 are mutually absolutely continuous, then so are $m_{\lambda f}$ and m_0, and

$$\log \frac{dm_{\lambda f}}{dm_0}(x) = \lambda\varphi(x) - \tfrac{1}{2}\lambda^2 C,$$

where $\varphi(x)$ obeys conditions which amount to linearity almost everywhere, and C is a constant. Further properties of the φ functional are deduced, particularly for the case when $f(t)$ has a representation in terms of the covariance kernel of the process, and the results are extended to the case of an infinite time interval.

P. Whittle (Manchester)

Seregin, L. V. 5279

Conditions for continuity of stochastic processes. (Russian. English summary)

Teor. Verojatnost. i Primenen. **6** (1961), 3–30.

Author's summary: "Let x_t, $0 \leq t \leq c < \infty$, be a separable stochastic process in metric space X. The main purpose of this paper is to derive conditions under which almost all sample functions of the process x_t are continuous. We designate $\rho(x, y)$ the distance between the points $x, J \in X$. Let $\mathrm{P}(\cdots)$ be a Markov transition function, satisfying for each $\varepsilon > 0$

$$\sup_{x,s,t} \mathrm{P}(s, x, t, V_\varepsilon(x)) = o(1), \qquad h \downarrow 0,$$

where $x \in X$; $s, t \in [0, c]$, $0 < t - s \leq h$ and $V_\varepsilon(x) = \{y : \rho(x, y) > \varepsilon\}$. Then almost all sample functions of the Markov process x_t are continuous if and only if for each $\varepsilon > 0$

$$\int_0^{c-h} \mathrm{P}\{\rho(x_t, x_{t+h}) > \varepsilon\}\, dt = o(h), \qquad h \downarrow 0.$$

Almost all sample functions of a martingale [semimartingale] x_t are continuous if and only if for $h \downarrow 0$

$$\int_0^{c-h} \mathrm{P}\{x_t < a, x_{t+h} > b\}\, dt = o(h),$$

$$\int_0^{c-h} \mathrm{P}\{x_t > b, x_{t+h} < a\}\, dt = o(h)$$

for each a and b $(a < b)$."

Sytaja, G. N. 5280

On a multiple stochastic integral. (Russian. English summary)

Ukrain. Mat. Ž. **16** (1964), 351–364.

Let $w(t)$ be a Brownian motion process defined in the interval $[0, T]$. Then K. Itô [Mem. Amer. Math. Soc. No. 4 (1951); MR **12**, 724] has defined the stochastic integral $\int_0^T f(t)\,dw(t)$ for a certain class of functions $f(t)$. In the present paper, the author discusses an analogous definition of the multiple stochastic integral

$$\int_0^T \cdots \int_0^T f(w(t_1), \cdots, w(t_m))\, dw(t_1) \cdots dw(t_m).$$

R. G. Laha (Washington, D.C.)

Čerkasov, I. D. 5281

Criteria for coordinate-homogeneity for continuous Markov processes. (Russian. English summary)

Teor. Verojatnost. i Primenen. **5** (1960), 229–237.

Author's summary: "Let us consider a Markov process with an infinitesimal operator

$$(*) \qquad A_t = A^i(t, x)\frac{\partial}{\partial x^i} + B^{ij}(t, x)\frac{\partial^2}{\partial x^i \partial x^j},$$

where $x = (x^1, \cdots, x^n)$ is a point in Riemann space V_n with a metric $g_{ij}(t, x)$. The necessary and sufficient conditions for the existence of a transformation $x^{i'} = x^{i'}(t, x^1, \cdots, x^n)$ which transforms the operator $(*)$ into the well-known operator $A_t^0 = B^{i'j'}(t)\,\partial^2/\partial x^{i'}\partial x^{j'}$ are given. At the end of the paper an example is given from statistics, in which these conditions are applied for establishing the density of the probabilities $f(t, x, \tau, \xi)$ of a certain Markov process."

Hanen, Albert 5282

Théorèmes limites pour une suite de chaînes de Markov.

Ann. Inst. H. Poincaré **18**, 197–301 (1963).

Let P_n, $n = 1, 2, \cdots$, be a sequence of $r \times r$ substochastic matrices converging to a stochastic limit P. Let ${}^{(n)}\xi_j(k)$ be the number of visits at j of the corresponding sub-Markov chain ${}^{(n)}X$ (with initial state i_0) in the first k steps. The paper is devoted to studying the limit laws for the vectors ${}^{(n)}\xi_j(k)$, $1 \leq j \leq r$, as n and $k \to \infty$. The methods are analytic and depend upon the expression of the characteristic function in the form

$$(1) \quad E\left[\exp \sum_{j=1}^{n} iu_j{}^{(n)}\xi_j(n) \,\Big|\, \{{}^{(n)}X_0 = i_0\}\right] = (P_n D_u)^n V_0(i_0),$$

where D_u is the diagonal matrix with terms $\exp(iu_j)$ and V_0 is the vector with all entries 1. By writing the operators $P_n D_u$ in the spectral representation, and considering them as perturbations of PD_u, application is made of the functional calculus of operators to obtain the limit characteristic functions in a neighborhood of the origin.

In Chapter 2, the fundamental case $P_n \equiv P$ is considered. A central limit theorem of Kolmogoroff and Mihoc is extended to allow P to contain transient states, and a (weak) law of large numbers is proved for general P. In Chapter 3, the sequence $P_n \to P$ is treated under the restriction that P contains no transient states. It is shown, for example (Theorem 3.3), that if P has only one ergodic class, and if the P_n are strictly stochastic, then the random variables $Y_{j,n} = ({}^{(n)}\xi_j(n) - n\Pi_j{}^*)/\sqrt{n}$, where Π^* is the P-invariant distribution, converge jointly in the weak sense to the normal limit law corresponding to P as in Chapter 2. If P has several ergodic classes E_i, and if (a) $n(1 - {}_i\lambda_{0,n}) \to q_i$, where ${}_i\lambda_{0,n}$ is the maximal positive eigenvalue of P_n restricted to $E_i \times E_i$, and (b) $nE({}_i\lambda_0)\,{}_{i,j}S_n V_0{}^j \to q_i{}^j$, where $E({}_i\lambda_0)$ is the projection associated with ${}_i\lambda_0(=1)$, ${}_{i,j}S_n$ is the restriction of P_n to $E_i \times E_j$, and $V_0{}^j$ is the restriction of V_0, then a law of large numbers (Theorem 3.4) for the vectors ${}^{(n)}\xi_j(n)/n$ is proved. This is used to show that the transitions among the ergodic classes of P are "asymptotically Markovian" with a limit process having Q as infinitesimal generator (Q has diagonal entries $-q_i$ and $q_i{}^j$ elsewhere). In Chapter 4 the principal results of

Chapter 3 are extended to cover the case in which P has transient states.

The last chapter studies the consequences of two alternative sets of hypotheses. In the first, P has one ergodic class but may have transient states. Then if $n^{\alpha}(P_n - P) \to S$ for some α, $0 < \alpha < 1$, and if $n^{\alpha}(Q_i(n) - Q_i) \to B_i(u) > 0$ for i transient, where $Q_i(n)$ is the minor relative to (i, i) of the determinant of $[P_n D_u - \lambda_{0,n}(u)I]$, $\lambda_{0,n}$ being the eigenvalue which approaches 1 as $u \to 0$, then a normal limit law is obtained. In the second situation, P has two acyclic ergodic classes but no transient states. It is assumed that $n(1 - \underset{1}{\lambda}_n) \to \infty$ and $n(1 - \underset{2}{\lambda}_n) \to q$, where $\underset{i}{\lambda}_n$, $i = 1$ or 2, are the maximal positive eigenvalues for the two classes. It is then shown (Theorem 5.2) that $(1 - \underset{1}{\lambda}_n)^{(n)}\xi_{1,n,i_0}$ (where ${}^{(n)}\xi_{1,n,i_0}$ is the number of visits in the first class up to the nth step) converges weakly to the limit with characteristic function $\exp[iuq/(1 - iu)]$, in accordance with a result of Dobrušin.

F. B. Knight (Urbana, Ill.)

Il'in, A. M.; Has'minskiĭ, R. Z. 5283

On the equations of Brownian motion. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 466–491.

Let $X_\mu(t)$, $Y_\mu(t)$ be the position and velocity, respectively, of a particle of mass m, moving on a line. The surrounding linear medium consists of particles of mass μ. A force field acts on the particle. Moreover, at times $\tau_1, \tau_2, \cdots$ (Poisson process, rate a) the particle has an elastic collision with a particle of the medium. The successive collisions are with particles having velocities $\eta_1, \eta_2, \cdots$, where these velocities are random variables with a common distribution and are independent of each other and of $\{\tau_n\}$. The (X_μ, Y_μ) process is a Markov process with stationary transition probabilities. If $u(x, y, t)$ is the expectation of $f[X_\mu(t), Y_\mu(t)]$ for a particle having initial position x and initial velocity y, it is shown that, under suitable restrictions on f and the force field, the function u satisfies an integro-differential equation. It is natural to identify $a\mu = A/2$ with viscosity, the expected value of $\mu\eta_k^2$ with temperature. If these two quantities and m are held constant while $\mu \to 0$, and if η_k has expectation 0 and third absolute moment $o(\mu^{-2})$, the equation satisfied by μ becomes a (phase space) diffusion equation. It is shown that the solutions of the original equation converge to those of the limit equation. The Green's function of the limit equation is the transition density of the limiting diffusion process. Possible generalizations are discussed briefly: The treatment can be extended to n-space. The particle can be supposed restricted to an open set whose boundary has suitable absorbing or reflecting properties.

Isaac, Richard 5284

A uniqueness theorem for stationary measures of ergodic Markov processes.

Ann. Math. Statist. **35** (1964), 1781–1786.

Consider a Markov chain with probabilities $P_a(B)$, let the non-negative mass distribution e be stable in the sense that $\int e(da)P_a[x_1 \in db] = e(db)$, and define $P_e(B) = \int e(da)P_a(B)$. If e is ergodic in the sense that for each tail event A with complement B either $P_e(A) = 0$ or $P_e(B) = 0$, then each stable mass distribution is a constant multiple of e. A sufficient condition that e be ergodic is that $e(Q) > 0$ entail $P_e[x_n \in Q \text{ i.o.}] > 0$.

H. P. McKean, Jr. (Cambridge, Mass.)

Kingman, J. F. C. 5285

On inequalities of the Tchebychev type.

Proc. Cambridge Philos. Soc. **59** (1963), 135–146.

Denote by $\mathscr{P}$ the set of random variables x satisfying

$$E[g_i(x)] = c_i \qquad (i = 0, 1, 2, \cdots, k)$$

(where $g_0(x) \equiv c_0 = 1$) and consider the evaluation of an upper bound for $E[f(x)]$, $x \in \mathscr{P}$. Isii [Ann. Inst. Statist. Math. Tokyo **10** (1959), 65–88; MR **21** #4492] has shown that the "method of Markov" gives a sharp upper bound; the author uses a much simpler convexity argument to establish the same result, enunciated in the paper as follows. Theorem 1: Suppose that $\mathscr{P}$ is non-empty, and that there exists no non-zero vector $\boldsymbol{\mu}$ such that, whenever $x \in \mathscr{P}$, $\boldsymbol{\mu} \cdot \mathbf{g}(x) = \boldsymbol{\mu} \cdot \mathbf{c}$ with probability one. Then either there exists a vector $\boldsymbol{\lambda} = (\lambda_0, \cdots, \lambda_k)$ such that, for all x,

$$(*) \qquad f(x) \leq \boldsymbol{\lambda} \cdot \mathbf{g}(x)$$

and such that

$$\sup_{x \in \mathscr{P}} Ef(x) = \boldsymbol{\lambda} \cdot \mathbf{c}$$

or no vector $\boldsymbol{\lambda}$ satisfies $(*)$ and $\sup_{x \in \mathscr{P}} Ef(x) = \infty$. The supremum is unaltered if $\mathscr{P}$ is replaced by the smaller class $\mathscr{P}_{k+1}$, the subset of $\mathscr{P}$ consisting of random variables taking at most $k+1$ different values.

Extensions and limitations of the method for the multi-variable situation are discussed.

The author devotes a final section to discussing bounds stronger than the Tchebychev bound, which, although not valid uniformly, are valid in the limit. In fact, he shows that if $\Phi_n = \sup_{x \in \mathscr{P}} Ef_n(x)$ and $f_n(x) = o(\Phi_n)$ for all x as $n \to \infty$, then, for each $x \in \mathscr{P}$,

$$Ef_n(x) = o(\Phi_n), \qquad n \to \infty.$$

P. Whittle (Manchester)

Knight, Frank; Orey, Steven 5286

Construction of a Markov process from hitting probabilities.

J. Math. Mech. **13** (1964), 857–873.

One of the most important problems in the current theory of Markov processes is that of constructing a process from given hitting probabilities (or harmonic measures, as the hitting probabilities are sometimes called). This problem is of special importance in studying the relationships between the axiomatic potential theory of Bauer or Brelot and the probabilistic potential theory of Hunt. It was shown by Blumenthal, the reviewer, and McKean [Illinois J. Math. **6** (1962), 402–420; MR **25** #5550] that under quite general conditions there can exist at most one process up to a change of time scale with given hitting probabilities. More recently, P. A. Meyer [Ann. Inst. Fourier (Grenoble) **13** (1963), fasc. 2, 357–372; MR **29** #260] has attacked the problem of constructing a Markov process corresponding to Brelot's axiomatic potential theory. The present authors approach the general problem

of constructing a Markov process with given hitting probabilities from a quite different direction. They show that under suitable conditions (which are not easily summarized) one can construct the desired Markov process as a limit of certain approximating random walks. As is usual in this type of problem, it is clear how the approximating random walks should be defined; the difficulty is in proving the convergence of the approximations and in obtaining the properties of the limit. The authors carry out this program in an elegant manner under reasonable assumptions on the hitting probabilities.

R. Getoor (Stanford, Calif.)

Matthes, Klaus 5287

Ergodizitätseigenschaften rekurrenter Ereignisse. I.
Math. Nachr. **24** (1962), 109–119.

The author considers a Markov chain $\{(i_n, X_n): n=0, 1, \cdots\}$ with state space the positive integers times the positive reals. (i_0, X_0) has some initial distribution. Given that $i_n = i$, the probability that $i_{n+1}=j$ is p_{ij}, independent of X_n. Given that $i_{n+1}=j$, the distribution of X_{n+1} is F_j, independent of everything else in the past of the process. One can think of $X_1, X_2, \cdots$ as the staying times in the successive states of the Markov chain $\{i_n: n=0, 1, \cdots\}$. $n_i(t)$ is the number of transitions into state i during $(0, t)$, $n(t)=\sum_i n_i(t)$, and $Z_t = i$ if the process is in state i at time t. Such processes are usually described as Markov renewal processes or semi-Markov processes (cf. R. Pyke [Ann. Math. Statist. **32** (1961), 1231–1242; MR **24** #A3712], where precise definitions can be found). Classical renewal theory considers the case where $i_1, i_2, \cdots$ can only take one value, i.e., the underlying Markov chain is trivial. For this case Blackwell [Pacific J. Math. **3** (1953), 315–320; MR **14**, 994] proved the existence of $\lim_{T\to\infty} E[N_i(T+t)-N_i(T)]$, and one also knows the limiting distribution $(T\to\infty)$ of Z_T and the time of the last transition before T [E. B. Dynkin, Izv. Akad. Nauk. SSSR Ser. Mat. **19** (1955), 247–266; MR **17**, 865]. The author generalizes these results to the above setup and phrases them in terms of weak convergence $(T\to\infty)$ of the stochastic processes $\{N_i(T+t)-N_i(T),\ Z_{T+t}: t\geq 0, i\geq 1\}$ to some stationary limiting process $\{\tilde{N}_i(t), \tilde{Z}_t: t\geq 0, i\geq 1\}$. Basically, these results have also been obtained by J. Th. Runnenburg [Thesis, Chapter 3, Univ. Amsterdam, Amsterdam, 1960; MR **26** #5649].

H. Kesten (Ithaca, N.Y.)

Matthes, Klaus; Nawrotzki, Kurt 5288

Ergodizitätseigenschaften rekurrenter Ereignisse. II.
Math. Nachr. **24** (1962), 245–253.

The notation is as in the preceding review of Part I [#5287]. In this part it is shown that for suitable initial distributions of (i_0, X_0) the convergence of the processes $\{N_i(T+t)-N_i(T), Z_{T+t}\}$ to $\{\tilde{N}(t), \tilde{Z}_t\}$ as $T\to\infty$ is actually of a stronger type than weak convergence. The key renewal theorem of W. L. Smith [Proc. Roy. Soc. Edinburgh Sect. A **64** (1954), 9–48; MR **15**, 722] is generalized and tied up with this stronger type of convergence for all initial distributions. {Remark: In the definition of $(F_i)\in\mathfrak{R}$ one should add on the last line of p. 248 "and $p_{i_1 i_2}p_{i_2 i_3}\cdots p_{i_{n-1} i_n}>0$".}

Moy, Shu-Teh C. 52

Generalizations of Shannon-McMillan theorem.
Pacific J. Math. **11** (1961), 705–714.

Let A be a non-empty set, $\mathscr{A}$ a σ-algebra of subsets of A, $X=\prod_{n\in Z} X_n$, where $X_n = A$ for all $n\in Z=\{\cdots, -1, 0, \cdots\}$. For each $n\in Z$ let pr_n be the projection of X on X_n. Denote by $\mathscr{B}$ and $\mathscr{B}_{n,m}$ ($n\in Z$, $m\in Z$, $n\leq m$) the σ-algebras generated by $\bigcup_{k\in Z}\mathrm{pr}_k^{-1}(\mathscr{A})$ and $\bigcup_{n\leq k\leq m}\mathrm{pr}_k^{-1}(\mathscr{A})$, respectively. For a probability λ on $\mathscr{B}$ denote by $\lambda_{n,m}$ the restriction of λ to $\mathscr{B}_{n,m}$ ($n\in Z$, $m\in Z$, $n\leq m$). Let now ν and μ be two probabilities on B such that (i) ν is stationary; (ii) μ is Markovian with stationary transition probabilities; (iii) $\nu_{n,m}$ is absolutely continuous with respect to $\mu_{n,m}$ for all $n\in Z$, $m\in Z$, $n\leq m$ (denote $f_{n,m}=d\nu_{n,m}/d\mu_{n,m}$). The main result of the paper is as follows. Assume that $\log f_{0,0}\in\mathscr{L}^1(\nu)$ and that there is a constant $M>0$ such that $\int(\log f_{0,n}-\log f_{0,n-1})d\nu\leq M$ for all $n\in N^*=\{1, 2, 3, \cdots\}$. Then the sequence $((\log f_{0,n})/n)_{n\in N^*}$ converges in $\mathscr{L}^1(\nu)$. This generalizes the mean convergence theorem in information theory of A. Perez [Trans. First Prague Conf. Information Theory, Statistical Decision Functions, Random Processes (Liblice, 1956), pp. 183–208, Publ. House Czech. Acad. Sci., Prague, 1957; MR **20** #6325; ibid., pp. 209–243; MR **2**[0] #6326; ibid., pp. 245–252; MR **20** #6327]. The paper contains also some other results of independent interest.

Moy, Shu-Teh C. 529

A note on generalizations of Shannon-McMillan theorem.
Pacific J. Math. **11** (1961), 1459–1465.

Let A, $\mathscr{A}$ and X, $\mathscr{B}$, $\mathscr{B}_{n,m}$ be as above [#5289]. Consider again two probabilities ν and μ on $\mathscr{B}$ satisfying the hypotheses (i), (ii) and (iii) and, as before, write $f_{n,m}=d\nu_{n,m}/d\mu_{n,m}$ ($n\in Z$, $m\in Z$, $n\leq m$). The author proves the following theorem. Assume that there is a constant $K>$[0] such that $\int(f_{0,n}/f_{0,n-1})d\nu\leq K$ for all $n\in N^*$. Then $\sup_{n\in N^*}|\log f_{-n,0}-\log f_{-n,1}|\in\mathscr{L}^1(\nu)$ and the sequence $((\log f_{0,n})/n)_{n\in N^*}$ converges almost everywhere with respect to ν. In a certain sense this theorem extends the pointwise convergence theorems in information theory of L. Breiman [Ann. Math. Statist. **28** (1957), 809–811; MR **19**, 1148; ibid. **31** (1960), 809–810] and K. L. Chung [ibid. **32** (1961), 612–614; MR **24** #A1630]. See also the reviewer's paper [Ark. Mat. 4 (1961), 235–247].

Branching processes with measure-valued states.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 333–357. *Publ. House Czech. Acad. Sci., Prague,* 1964.

The author studies branching processes where there are a continuum of different types of particles, distinguished by means of a continuous variable τ. The state space M is the set of finite measures μ on the real line, and the probability mechanism is determined by a transition function $P(s, \mu, t, U)$, $s \leq t \in T = \{0, 1, \cdots\}$, $\mu \in M$, U in $\mathcal{M}$ (an appropriate σ-algebra of subsets of M). The main results, which are too detailed to reproduce here, give necessary and sufficient conditions for the extinction with probability one of all particles in the case of time homogeneous processes.

Koutský, Z. 5294

Periodische Verzweigungsfolgen.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 429–439. *Publ. House Czech. Acad. Sci., Prague,* 1964.

The author considers a modification of the Galton-Watson model and its vector-valued generalization, which he calls a periodic branching process. Specifically, a periodic branching process of period k is a sequence of random variables ξ_t, $t = 0, 1, 2, \cdots$, with

$$P\{\xi_{tk+j+1} = r \mid \xi_{tk+j} = 1\} = P\{\xi_{j+1} = r \mid \xi_j = 1\}$$

for $j = 0, 1, 2, \cdots, k-1$; $t = 0, 1, 2, \cdots$, and the conditional distribution of ξ_{tk+j+1} given $\xi_{tk+j} = r$ is the distribution of the sum of r independent random variables, each of which has the same distribution as ξ_{tk+j+1} given $\xi_{tk+j} = 1$.

Then, if this process is observed at interval k, the resulting sequence of random variables is easily seen to be a homogeneous branching process and the usual results follow immediately under the usual regularity conditions. A similar treatment of the periodic branching process in the vector-valued case is also carried out.

Bernard Harris (Madison, Wis.)

Skorohod, A. V. 5295

Branching diffusion processes. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 492–497.

Der Verfasser behandelt Verallgemeinerungen der von B. A. Sevast'janov [Teor. Verojatnost. i Primenen. **3** (1958), 121–136; MR **20** #4332; ibid. **6** (1961), 276–286; MR **24** #A3005] definierten Verzweigungsprozesse mit Diffusion, wobei die Diffusionskoeffizienten vom Ort und der Zeit abhängen dürfen. Es wird eine Differentialgleichung angegeben für die erzeugende Funktion der Übergangswahrscheinlichkeiten $V(x, t, T, k_1, A_1, \cdots, k_r, A_r)$, d.h. der bedingten Wahrscheinlichkeiten, daß zur Zeit T in den Mengen $A_1, \cdots, A_r$ jeweils $k_1, \cdots, k_r$ Teilchen sind, unter der Annahme, daß sich zur Zeit t ein Teilchen im Punkt x des m-dimensionalen Raumes R befand.

In einer weiteren Verallgemeinerung wird R durch einen beliebigen topologischen Raum X ersetzt und ein Verzweigungsprozess ξ_t mit Diffusion auf dem Phasenraum $X_s^{(\infty)} = \bigcup_{l=0}^{\infty} X_s^{(l)}$ definiert, wobei $X_s^{(l)}$ der Raum der Punkte $(x_1, \cdots, x_l)$, $x_i \in X$, ist, in welchem diejenigen Punkte identifiziert werden, die sich nur in der Reihenfolge der Elemente $x_1, \cdots, x_l$ unterscheiden. Für die bedingte Erwartung

$$\mathbf{E}[f(\xi_t) \mid \xi_0 \in X_s^{(1)}; \xi_0 = (x)]$$

wo f eine stetige, durch 1 beschränkte Funktion auf X mit

$$f(\xi_t) = 1 \qquad \text{für } \xi_t \in X_s^{(0)},$$
$$= f(x_1) \cdots f(x_l) \text{ für } \xi_t \in X_s^{(l)}, \ \xi_t = (x_1, \cdots, x_l),$$

ist, wird eine Integralgleichung abgeleitet.

Bei der Erweiterung dieses Modells auf r Teilchentypen tritt ein System von Integralgleichungen auf.

Some methods of obtaining exact estimates for the parameter of a stationary Gaussian process. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 516–519.

Author's summary: "The paper deals with stochastic processes $\xi(t)$ and $\eta(t)$ $(0 \leq t \leq T)$ having stationary Gaussian increments, zero means and spectral densities $f_\xi(\lambda)$ and $f_\eta(\lambda) = f_\xi(\lambda) + cf_\zeta(\lambda)$, respectively, where $f_\xi(\lambda)$ and $f_\zeta(\lambda)$ are known non-negative functions, and $c \geq 0$ is an unknown parameter. It is assumed that the Gaussian measures in the function space corresponding to the processes $\xi(t) - \xi(0)$ and $\eta(t) - \eta(0)$ are orthogonal for $c > 0$. We give the functionals of sample functions of the process $\eta(t)$ which could be used for the exact determination of the parameter c."

D. A. Darling (Ann Arbor, Mich.)

Blum, J. R.; Rosenblatt, Judah 5299

On random sampling from a stochastic process.

Ann. Math. Statist. **35** (1964), 1713–1717.

Let $\{X_n, n = 1, 2, \cdots\}$ be a stationary, ergodic sequence. All the finite-dimensional distributions of the X's can be consistently estimated by means of the observations $X_1, \cdots, X_n$ for $n \to \infty$. For a subsequence $\{k_n\}$ of the positive integers, the subsequence $\{X_{k_n}\}$ is not necessarily stationary. Even if it is stationary and ergodic, the finite-dimensional distributions of the original process may not be estimable from the observed subsequence.

The authors handle the case in which $\{k_n\}$ is not a fixed sequence but a sequence of positive, integer-valued random variables which are partial sums of elements of a stationary, ergodic sequence $\{Y_n\}$, i.e., $k_n = Y_1 + \cdots + Y_n$. The bivariate process $\{Y_n, Z_n\}$, where $Z_n = X_{k_n}$, is studied; for simplicity, the results are given for random variables X_n assuming only the values 0 and 1. It is shown that the process $\{Y_n, Z_n\}$ is stationary. The prime results are the following. $\{Y_n, Z_n\}$ is ergodic, and the finite-dimensional distributions of the $\{X_n\}$ process are consistently estimable from observations of the $\{Y_n, Z_n\}$ process under either of the following two hypotheses: (i) $\{X_n\}$ is stationary and ergodic; $\{Y_n\}$ is a sequence of independent, identically distributed random variables, distributed independently of the $\{X_n\}$ process; and $P\{Y_1 = 1\} > 0$; or (ii) $\{X_n\}$ is stationary and (uniformly strongly) mixing; $\{Y_n\}$ is stationary, ergodic, and independent of the $\{X_n\}$ process; and $P\{Y_1 = 1, \cdots, Y_m = 1\} > 0$, $m \geq 1$.

On the normal stationary process—areas outside given levels.

J. Roy. Statist. Soc. Ser. B **25** (1963), 189–194.

Author's summary: "Let $x(t)$ be a normal stationary process, observed for $0 \leq t \leq T$, and c a given positive constant. Formulae are derived for the mean and variance of the area above the level $+c$ formed by the process $x(t)$ in $(0, T)$. Corresponding results are obtained for the sum and the difference of the areas above the level $+c$ and below the level $-c$."

Rozanov, Ju. A. 5302

On the equivalence of probability measures corresponding to a Gaussian stationary process. (Russian)

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (Liblice, 1962), pp. 599–604. *Publ. House Czech. Acad. Sci., Prague,* 1964.

Let $\xi_0(t)$, $\xi(t)$, $0 \leq t \leq T$, be real Gaussian stationary processes and $P_0(d\omega)$, $P(d\omega)$, $\omega \in \Omega$, be, respectively, the corresponding probability measures on the space Ω of sample functions. As is well known [cf. J. Feldman, Pacific J. Math. 8 (1958), 699–708; MR **21** #1546], either $P_0 \sim P$ (mutually absolutely continuous) or $P_0 \perp P$ (singular). The author now proves the following theorem: Suppose ξ_0 has the spectral density $f_0(\lambda)$ subject to the condition that

$$\limsup_{\lambda \to \infty} \lambda^{2m} f_0(\lambda) < \infty, \qquad \liminf_{\lambda \to \infty} \lambda^{2n} f_0(\lambda) > 0$$

for certain natural numbers m, n $(n \geq m)$, let $B(t)$, $B_0(t)$ be, respectively, the correlation functions of ξ_0 and ξ, and put $\Delta(t) = B(t) - B_0(t)$; then for $P \sim P_0$, it is sufficient that $\Delta(t)$, $-T \leq t \leq T$, has an absolutely continuous $(2n-1)$st derivative satisfying

$$(1) \qquad \int_0^T \int_0^T |\Delta^{(2n)}(s-t)|^2 \, ds dt < \infty;$$

the condition (1) with n replaced by m is also necessary for $P \sim P_0$. This is a generalization of the author's previous result which corresponds to the special case $m = n$ [Teor. Verojatnost. i Primenen. 8 (1963), 241–250; MR **27** #5295]. *G. Maruyama* (Fukuoka)

Rozanov, Ju. A. 5303

Probability measures in functional spaces corresponding to stationary Gaussian processes. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 448–465.

Die Arbeit beschäftigt sich mit der Totalstetigkeit zweier Wahrscheinlichkeitsmaße $P(dx)$ und $P_1(dx)$, die den Gaußschen stationären Prozessen $\xi(t)$ und $\xi_1(t)$, $0 \leq t \leq T$, entsprechen. Sie enthält neben einem Überblick über die bisherigen Resultate von M. S. Pinsker [*Information and informational stability of random variables and processes* (Russian), Izat. Akad. Nauk SSSR, Moscow, 1960], J. Feldman [Pacific J. Math. **10** (1960), 1211–1220; MR **24** #A3688], V. G. Alekseev [Dokl. Akad. Nauk SSSR **147** (1962), 751–754; MR **26** #4398], vom Verfasser [Teor. Verojatnost. i Primenen. 7 (1962), 84–89; ibid. 8 (1963), 241–250; MR **27** #5295], und anderen auch einige neue Ergebnisse. Ein einfacher Beweis wird dafür gegeben, daß die Wahrscheinlichkeitsmaße $P(dx)$ und $P_1(dx)$ singulär sind, wenn $\lim_{\lambda \to \infty} \lambda^\beta [f_1(\lambda) - f(\lambda)] = \infty$; hier sind f und f_1 die Spektraldichten von $\xi(t)$ und $\xi_1(t)$, $\beta = \alpha + \frac{1}{2}$, wobei für die Dichte f gilt: $\lim_{\lambda \to \infty} \lambda^\alpha f(\lambda) > 0$ für ein $\alpha > 0$. Da sich die Wahrscheinlichkeitsmaße $P(dx)$ und $P_1(dx)$ und die Korrelationsfunktionen $B(t)$ und $B_1(t)$ der entsprechenden Prozesse gegenseitig bestimmen, lassen sich die Kriterien

für die Totalstetigkeit dieser Maße natürlicher mit Hilfe von $B(t)$ und $B_1(t)$ formulieren. Als Beispiel sei folgender Satz zitiert: Die Bedingung $\int_0^T \int_0^T [A^{(2m)}(s-t)]^2 ds dt < \infty$, wobei $A(t) = B(t) - B_1(t)$, ist hinreichend für die Totalstetigkeit von $P(dx)$ und $P_1(dx)$, wenn $0 < \liminf_{\lambda\to\infty} \lambda^{2m} f(\lambda)$, und notwendig, wenn $\limsup_{\lambda\to\infty} \lambda^{2m} f(\lambda) < \infty$.

Ferner werden einige Eigenschaften der Korrelationsfunktion $B(t)$ angegeben, die mit Wahrscheinlichkeit 1 mittels eines endlichen Abschnittes einer Trajektorie $x(t)$, $0 \leq t \leq T$, bestimmt werden können.

The correlated unrestricted random walk.

J. Roy. Statist. Soc. Ser. B **25** (1963), 394–400.

Author's summary: "A particle performs an unrestricted correlated random walk along a straight line with a velocity constant in magnitude but variable in direction. This direction remains constant for every time interval of unit length, and with probability p it is the same as in the previous interval and with probability $1-p$ it is reversed. The object of this paper is to obtain probabilities for the first passage to position r, the jth return to the origin and cognate results."

Dhondt, André 5305

Solution transitoire de la file poissonienne à plusieurs stations.

Cahiers Centre Études Recherche Opér. **4** (1962), 161–178.

This paper is devoted to a study of the non-stationary behaviour of a queueing system with S servers, Poisson arrivals, exponential service time and first-come, first-served discipline. The approach is similar to that of S. Karlin and J. McGregor [Pacific J. Math. 8 (1958), 87–118; MR **20** #3611] but uses mathematically simpler techniques. Equations for the Laplace transforms of the probabilities that n people are in the system at time t are easily written down. The first S of these involve $S+1$ unknowns. A further equation is produced by combinations of the remaining equations, and the total of $S+1$ equations solved. The solutions of the remainder then follow easily. The inversions of the Laplace transforms depend upon the locations of the roots of certain equations, and these are discussed in detail. The final expressions for the probabilities are given as the sum of the residues at certain well-located points. *D. V. Lindley* (Aberystwyth)

Authors' summary: "An incorrect assumption of independence produced an error in the waiting-time distributions derived in same J. **23** (1961), 113–127 [MR **23** #A2959]. The correct distributions are derived here."

Prohorov, Ju. V. 5308

Transition phenomena in queueing processes. I. (Russian. Lithuanian and English summaries)

Litovsk. Mat. Sb. **3** (1963), *no.* 1, 199–205.

In a simple queue let the inter-arrival and service time distributions have, among other restrictions, respective means $\alpha > 1$ and 1. Setting $\alpha = (1-\delta)^{-1}$, $\delta > 0$, the author considers the limiting form of the distribution of W_n, the waiting time of the nth item to be serviced, when $\delta \to 0$. If $n\delta^2 \to \tau > 0$, it is shown that $\Pr\{W_n \leq x/\delta\} \sim \Pr\{\xi(t) < \frac{1}{2}(x+t), 0 \leq t \leq \tau\}$, where $\xi(t)$ is the standard Wiener process. If $n\delta^2 \to \infty$, $\Pr\{W_n \leq x/\delta\} \sim 1 - e^{-x}$. If $F_\delta(x)$ is the stationary distribution of W_n, one has $F_\delta(x/\delta) \to 1 - e^{-x}$.

Weiss, George H. 5309

An analysis of pedestrian queueing.

J. Res. Nat. Bur. Standards Sect. B **67B** (1963), 229–243.

Queue distributions are obtained for pedestrians who wait to cross through gaps in a traffic stream. The pedestrians have a Poisson arrival distribution; the traffic stream has independent gaps; and a pedestrian will accept a gap of length t with probability $\alpha(t)$. The author obtains the steady-state queue distributions using renewal type arguments. The $\alpha(t)$ apparently has the following more precise interpretation. At the start of a new gap of length t all queued pedestrians as a group either accept or reject the gap with probability $\alpha(t)$ or $1-\alpha(t)$, respectively, independent of any past history of previous rejections. Any pedestrian that arrives after the start of a gap, however, will accept a residual gap of length τ with probability $\alpha(\tau)$, independent of whether or not other pedestrians may have already rejected the original gap or any part thereof. It is difficult to imagine what kind of people or things might behave in this way. *G. Newell* (Providence, R.I.)

MacKinnon, William J. 5315

Table for both the sign test and distribution-free confidence intervals of the median for sample sizes to 1,000.

J. Amer. Statist. Assoc. **59** (1964), 935–956.

Consider the results of n independent trials of an event for which the probability of occurrence on a single trial is $\frac{1}{2}$. Let s and r, where $s+r=n$, be respectively the number of occurrences and non occurrences of the event in question, or vice versa, whichever satisfies the condition $s \leqq n/2 \leqq r$. The two-tailed probability that the number x, representing either the number of occurrences or the number of non-occurrences, will be less than or equal to s when the number of trials is n is given by $P(x \leqq s \mid n) = (\frac{1}{2})^{n-1} \sum_{x=0}^{s} n!/x!(n-x)!$, $x = 0, 1, \cdots, [n/2]$. Let h be the significance level for the two-sided test. Then the critical value of s for particular values of n and h is the largest value of s such that $P(x \leqq s \mid n) \leqq h$. Dixon and Mood [same J. 41 (1946), 557–566] published a table of critical values of s for $n = 1(1)100$ and four values of h. Such a table is useful not only in sign tests but also in distribution-free estimation of the median of a population. The author [ibid. 54 (1959), 164–172] published a sign-test table for twelve values of h, replacing n by $d = r - s$ and extending the range of sample sizes to 1,000. The latter table suffers the drawbacks that it is complicated to use and does not facilitate the determination of confidence intervals for the median. In the present paper the author gives a table, derived from the one in his previous paper but using n instead of d, for $n = 1(1)1000$ and six values of h, thus combining the best features of both the previous tables (the extent of his own earlier table and the convenience and versatility of the Dixon-Mood table). The method of derivation and several examples of the use of the table are given. *H. L. Harter* (Dayton, Ohio)

Danziger, L.; Davis, S. A. 5316

Tables of distribution-free tolerance limits.

Ann. Math. Statist. **35** (1964), 1361–1365.

The paper is concerned with probabilities K that N_0 or more independent observations $Y_1, \cdots, Y_N$ with a continuous density will lie between the r_1th and r_2th order statistic of some other independent sample $X_1, \cdots, X_n$ from the same distribution. These probabilities are shown to depend on $r = r_1 + n + 1 - r_2$ only. In the table are given N_0 corresponding to $K = 0{,}50$; $0{,}75$; $0{,}90$; $0{,}95$; $0{,}99$; $r = 1, 2, \cdots, 10$; N, $n = 5, 10, 25, 50, 75, 100$. Also $\lim N_0/N$ for $N \to \infty$ is tabulated. *J. Hájek* (Prague)

Dąbek, Marian 5319

On the speed of convergence of sums and differences. (Polish and Russian summaries)

Ann. Univ. Mariae Curie-Skłodowska Sect. A **16** (1962), 101–106 (1964).

Let $\{\xi\}$ and $\{\xi_n'\}$ be two sequences of independent random variables each having moments of all orders and each satisfying Lyapounov's condition for the third central moment; moreover, for every n, ξ_n and ξ_n' are identically distributed. Let $S_N = \sum_{n=1}^{N} \xi_n$, $S_N' = \sum_{n=1}^{N} \xi_n'$, and $Z_N = S_N + S_N'$ and $Y_N = S_N - S_N'$.

In the present paper, the author compares the rates of convergence of the sequences of random variables $\{Y_N\}$ and $\{Z_N\}$. The author proves that (i) if all the random variables ξ_n are symmetric, then the sequence $\{Y_N\}$ converges as quickly as the sequence $\{Z_N\}$, but (ii) if at least one random variable ξ_n is not symmetric, then the sequence $\{Y_N\}$ converges more quickly than the sequence $\{Z_N\}$. *R. G. Laha* (Washington, D.C.)

Eagleson, G. K. 5320

Polynomial expansions of bivariate distributions.

Ann. Math. Statist. **35** (1964), 1208–1215.

Suppose that W_1, W_2, W_3 are independent random variables belonging to a family $\mathscr{F}$ which is closed under convolutions. Then $X = W_1 + W_2$ and $Y = W_2 + W_3$ belong to the same family but are correlated. Suppose also that the distributions of $\mathscr{F}$ have a generating function for their orthogonal polynomials $\{P_n(x)\}$ of the form

$$G(t, x) = f(t)e^{xu(t)} = \sum_0^\infty P_n(x)t^n/n!.$$

The author studies the properties of the bivariate distribution functions of X and Y which result from these conditions and are ϕ^2-bounded [H. O. Lancaster, same Ann. **29** (1958), 719–736; MR **21** #944]. He distinguishes five types of distributions, depending on the values of parameters in a recurrence relation connecting $\{P_n(x)\}$.

R. L. Plackett (Newcastle upon Tyne)

Ewens, W. J. 5321

Two asymptotic results in sequential analysis.

Austral. J. Statist. **5** (1963), 1–4.

The standard Wald likelihood ratio sequential test with respect to a random variable x is assumed: sampling is continued until $z_1 + \cdots + z_r + \cdots$ goes outside a fixed interval, where the $\{z_i\}$ are independent log-likelihood ratios. Asymptotic here means the two hypotheses tested are infinitesimally close (and the A.S.N. $\to \infty$); this implies z is an infinitesimal variable and the process becomes one of diffusion, with the consequence that it is independent of the original d.f. of x. (This result is due to Bartlett (1944) [cf. M. S. Bartlett, *An introduction to stochastic processes, with special reference to methods and applications*, Cambridge Univ. Press, Cambridge, 1955; MR **16**, 939].) As a corollary of this, the problem of the behaviour of the sequential test between two values of the variance in normal samples with known mean when, in fact, the population is non-normal, is examined. It is shown that the same factor, $1 + \frac{1}{2}\gamma$, governs the effect of non-normality in the sequential case, as was found by Box in the fixed sample case. (γ is the kurtosis of the actual non-normal distribution.)

D. E. Barton (London)

Ferguson, Thomas S. 5322

A characterization of the exponential distribution.

Ann. Math. Statist. **35** (1964), 1199–1207.

In the present paper the author proves the following theorem. Let X and Y be two independent random variables each having absolutely continuous distribution functions. Then the random variables $U = \min(X, Y)$ and $V = X - Y$ are independent if and only if both X and Y have exponential distributions with the same location parameter.

R. G. Laha (Washington, D.C.)

Finucan, H. M. 5323

A note on kurtosis.

J. Roy. Statist. Soc. Ser. B **26** (1964), 111–112.

Author's summary: "This note 'rediscovers' the original interpretation of kurtosis as an indicator of 'a prominent peak and a prominent tail' on the density curve. A formal proof that such curves have indeed relatively high fourth moments is given. A comment is made concerning the recent decline of this correct classical interpretation."

Hanson, D. L.; Koopmans, L. H. 5324

Tolerance limits for the class of distributions with increasing hazard rates.

Ann. Math. Statist. **35** (1964), 1561–1570.

Let $Y_1, \cdots, Y_n$ be a sample from a distribution $F(x)$, and $X_1, \cdots, X_n$ the same values arranged in order. Non-parametric tolerance limits for $F(x)$ have the disadvantage that there is a minimum sample size below which the tolerance limits cannot be satisfied. The authors construct and study tolerance limits of the form $X_{n-k-j} + b(X_{n-k} - X_{n-k-j})$ $(b > 1)$ which are always satisfactory for absolutely continuous distributions which are increasing hazard rate distributions, and more particularly, Pólya frequency functions of order two. Monte Carlo comparisons with parametric tolerance limits are discussed.

Watanabe, Yoshikatsu 5325

The Student's distribution for a universe bounded at one or both sides. IV.

J. Gakugei Tokushima Univ. **14** (1963), 1–53.

Parts I, II, and III appeared in same J. **11** (1960), 11–51 [MR **25** #1595]; ibid. **12** (1961), 5–50; ibid. **13** (1962), 1–42. Author's introduction: "In the present note the author treats the most general form for the volume-element of the first half, i.e., one-sided case of the proposed theme, and has gained its general information, at least theoretically. Naturally, to get actual solutions for concrete cases of several sizes $n = 6, 7, \cdots$, it requires a vast bulk of computations which could be accomplished only by making constant use of electronic computers, etc. Also the results reported in the preceding notes are now supplemented with possible improvements, sometimes rebuilt to get a better insight, or made to be more general and intelligible. Lastly, to reveal the general feature of its application, the T.N.D. is exemplified by the special case $n = 4$."

Kotlarski, Ignacy 5326

On bivariate random variables where the quotient of their coordinates follows some known distribution.

Ann. Math. Statist. **35** (1964), 1673–1684.

In the present paper the author derives a characterization of the class $\mathscr{X}$ of all distribution functions $F(x, y)$ of bivariate random variables (ξ, η), where the coordinates ξ and η are identically distributed, and, moreover, the quotient ξ/η follows the Cauchy law. A similar characterization is also obtained for the class $\mathscr{Y}$ of all distribution functions $F(x, y)$ of bivariate random variables (ξ, η), where ξ and η are positive random variables, and, moreover, the quotient ξ/η has an F-distribution. The method of Mellin transforms is the main tool of the present investigation of the author.

Pillai, K. C. Sreedharan 5327

On the moments of elementary symmetric functions of the roots of two matrices.

Ann. Math. Statist. **35** (1964), 1704–1712.

This paper presents two lemmas for evaluating the moments of elementary symmetric functions (esf's) of the non-null characteristic roots of a matrix, useful in certain problems of multivariate analysis. The preliminary lemma shows how to express the product of an sth-order Vandermonde determinant and the kth ($k \geq 0$) and lth ($l \geq 0$) powers of the rth and hth ($r, h \leq s$) esf's as a linear compound of determinants. This is extended to products of powers of any number of esf's up to the sth. Then, using the preliminary lemma and reduction formulae for certain Vandermonde determinants, the second lemma shows how the moments of the esf functions of the s non-null characteristic roots of a matrix can be derived from formulae for moments of corresponding esf's in s non-null roots of another matrix, and vice versa. Illustrations are given.

P. S. Dwyer (Ann Arbor, Mich.)

Zinger, A. A.; Linnik, Ju. V. 5328

Polynomial statistics for a normal law and those related to it. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 547–550.

The authors consider a class of n-dimensional distributions, including all regular normal distributions and distributions with density $\prod_{i=1}^{n} f(x_i)$, where f satisfies a differential equation $f^{(\nu)}(x)+\sum_{j=1}^{\nu} P_j(x) f^{(\nu-j)}(x)=0$, with the P_j denoting certain polynomials. For this class they show that two polynomial statistics $Q_1=Q_1(\xi)$ and $Q_2=Q_2(\xi)$ have the same distribution if and only if $Eh_j(Q_1)=Eh_j(Q_2)$, where $h_1, \cdots, h_M$ is a finite set of functions. Similarly, Q_1 and Q_2 are independent if and only if $E(h_j(Q_1)g_k(Q_2))=Eh_j(Q_1)Eg_k(Q_2)$, where $h_1, \cdots, h_M$, $g_1, \cdots, g_M$ is a finite set of functions. The functions h_j and g_j are of the form $h_j(x)=x^j \exp(-\sigma(x))$, $\sigma(x)$ being a polynomial.

Bennett, B. M. 5329

On combining estimates of a ratio of means.

J. Roy. Statist. Soc. Ser. B **25** (1963), 201–205.

Author's summary: "For a bivariate normal distribution with variances and covariance given multiples of an unknown σ^2, methods are presented for the combination of several separate estimates of the ratio of means, and for assessing confidence limits when an estimate of σ^2 is available. A numerical example is presented of the application of this method in combining estimates of relative potency based on several parallel line assays of insulin."

Birch, M. W. 5330

Maximum likelihood in three-way contingency tables.

J. Roy. Statist. Soc. Ser. B **25** (1963), 220–233.

Author's summary: "Interactions in three-way and many-way contingency tables are defined as certain linear combinations of the logarithms of the expected frequencies. Maximum-likelihood estimation is discussed for many-way tables and the solutions given for three-way tables in the cases of greatest interest."

Edwards, A. W. F. 5331

Estimation of the parameters in short Markov sequences.

J. Roy. Statist. Soc. Ser. B **25** (1963), 206–208.

Author's summary: "A parametric representation of a two-state Markov process is given which enables the maximum-likelihood estimates of the two parameters to be found without iteration."

Herbst, Laurence J. 5332

A test for variance heterogeneity in the residuals of a Gaussian moving average.

J. Roy. Statist. Soc. Ser. B **25** (1963), 451–454.

Author's summary: "A large sample test for variance heterogeneity in the residuals of a Gaussian moving average is presented, based upon periodogram-ratios of the data. For long series, it is shown that neither the null-hypothesis nor alternative-hypothesis behaviour of the test statistic is dependent upon the coefficients of the moving average (and these need not be estimated in advance). The alternative-hypothesis behaviour of the test statistic is discussed in terms of the coefficients in a Fourier expansion of the non-constant variance function."

McCord, James R. 5333

On asymptotic moments of extreme statistics.

Ann. Math. Statist. **35** (1964), 1738–1745.

Let Y_n be the maximum of n independent observations of a random variable X with distribution function F such that if $F(a_2)=1$ and $F(x)<1$ for $x<a_2$, then F has a continuous derivative f on some open interval (a_1, a_2), let μ_n and σ_n^2 be the mean and variance of Y_n, let $\lambda_k=E(|X-a|^k)$, and let u_n be defined by $1-F(u_n)=1/n$. Then (1) If there are real constants a, $b>0$, and $c>0$ such that $F(a)=1$, $F(x)<1$ for $x<a$, and, as $x \to a^-$, $1-F(x) \simeq b(a-x)^c$, $f(x) \simeq bc(a-x)^{c-1}$, then $E[(a-Y_n)^k] \simeq (bn)^{-k/c} \times \Gamma[1+(k/c)]$ as $n \to \infty$ ($k>-c$, $\lambda_k<\infty$) [or $E[(a-Y_n)^k] \simeq (a-u_n)^k \Gamma[1+(k/c)]$ as $u_n \to a^-$], whence $\sigma_n^2 \simeq (bn)^{-2/c} \times \{\Gamma[1+(2/c)]-\Gamma^2[1+(1/c)]\}$ as $n \to \infty$ ($\lambda_2<\infty$); (2) If there are real constants a, $b>0$, and $c>0$ such that $F(x)<1$ for $x<\infty$ and, as $x \to \infty$, $1-F(x) \simeq b(x-a)^{-c}$, $f(x) \simeq bc(x-a)^{-c-1}$, then $E[(Y_n-a)^k] \simeq (bn)^{k/c} \Gamma[1-(k/c)]$ as $n \to \infty$ ($k<c$, $\lambda_k<\infty$) [or $E[(Y_n-a)^k] \simeq (u_n-a)^k \Gamma[1-(k/c)]$ as $u_n \to \infty$], whence $\sigma_n^2 \simeq (bn)^{2/c}\{\Gamma[1-(2/c)]-\Gamma^2[1-(1/c)]\}$ as $n \to \infty$ ($c>2$, $\lambda_2<\infty$); (3) If there are real constants a, $b>0$, $c>0$ and $r>0$ such that $F(x)<1$ for $x<\infty$ and, as $x \to \infty$, $1-F(x) \simeq r \exp[-b(x-a)^c]$, $f(x) \simeq bcr(x-a)^{c-1} \exp[-b(x-a)^c]$, then $E[(Y_n-a)^k] \simeq (b^{-1} \ln rn)^{k/c}$ as $n \to \infty$ ($\lambda_k<\infty$) [or $E[(Y_n-a)^k] \simeq (u_n-a)^k$ as $u_n \to \infty$]. The author conjectures that, in the third case, $\sigma_n^2 \simeq (1/6)(\pi/bc)^2(b^{-1} \ln rn)^{(2/c)-2}$ ($\lambda_2<\infty$), and gives examples for which the conjecture holds.

D. R. Barr (Dayton, Ohio)

Rice, John R.; White, John S. 5334

Norms for smoothing and estimation.

SIAM Rev. **6** (1964), 243–256.

The authors compare the variances of the median, mean, and the midrange in samples from various distributions by actual sampling. Their conclusion that, depending on the parent distribution, one or another statistic is more efficient is well known and could have been reached easily without making the computer work.

M. M. Siddiqui (Fort Collins, Colo.)

Walker, A. M. 5335

A note on the asymptotic efficiency of an asymptotically normal estimator sequence.

J. Roy. Statist. Soc. Ser. B **25** (1963), 195–200.

Author's summary: "This paper gives a rigorous yet quite elementary proof that under fairly general conditions, the asymptotic efficiency of an asymptotically normal estimator sequence does not exceed unity. Both estimation of a single parameter and simultaneous estimation of several parameters are considered."

Anscombe, F. J. 5336

Tests of goodness of fit.

J. Roy. Statist. Soc. Ser. B **25** (1963), 81–94.

Author's summary: "An explicit account is given of a procedure for assessing goodness of fit of some observations with a hypothesis, generally known as a 'test of significance'; the description is close in spirit to R. A. Fisher's original conception. The relation of this test procedure with Bayesian procedures and with the Neyman-Pearson theory of tests is discussed. Some very tentative suggestions are made regarding the choice of a test criterion and the use to which the result of the test can be put. The role of conditional sampling distributions is studied. Various examples are discussed. In particular, a brief exploration is made in the apparently virgin territory of testing goodness of fit when the observations have been taken according to a sequential rule."

Inselmann, Edmund H. 5337

Hypothesis testing of Gaussian processes with composite alternatives.

J. Soc. Indust. Appl. Math. **12** (1964), 370–385.

A radar signal $s(t)$ is defined on the unit circle, $0 \leq t < 2\pi$. It is supposed that $s(t) = n(t) + u(t)$, where $n(t)$ is white Gaussian noise and $u(t)$ is a signal of known form but unknown location on the unit circle, that is, it is equal to $u(t-\theta)$, where $u(\cdot)$ is known but θ is not. It is desired to test the simple null hypothesis that the signal is absent against the composite alternative that it is present. The statistics used are the observable coordinates

$$s_k = \int_0^{2\pi} s(t)\exp(ikt)\,dt$$

for $k \leq n$. The suggested test is to reject when

$$\prod_{k<n} \mathrm{I}_0(|s_k u_k|/2S_k^2) > c,$$

where $\mathrm{I}_0(\cdot)$ is the Bessel function of the first kind with pure imaginary argument, $u_k = \int_0^{2\pi} u(t)\exp(ikt)dt$, and S_k is the standard deviation of the noise. This test is shown to be optimum in three senses indicated by the following considerations: (i) least favourable distributions, (ii) Bayes solution with probability $\frac{1}{2}$ on the null hypothesis, (iii) invariance. Numerical methods of performing the test are indicated. The last part of the paper extends the problem to the case where several sweeps of the unit circle may be made and a decision has to be made whether to carry out a further sweep or decide the signal is present.

Moses, Lincoln E. 5338

One sample limits of some two-sample rank tests.

J. Amer. Statist. Assoc. **59** (1964), 645–651.

From the author's introduction and summary: "There are many familiar two-sample tests of composite hypotheses which reduce to corresponding one-sample tests of simple hypotheses as one of the two samples is allowed to become infinite. The same thing holds for a number of rank tests. This paper exhibits such a correspondence between a two-sample rank test of Lehmann's [E. Lehmann, Ann. Math. Statist. **24** (1953), 23–43; MR **14**, 888] and (1) Fisher's [R. A. Fisher, *Statistical methods for research workers*, twelfth edition, Hafner, New York, 1950] test for combining independent significance tests, or (2) a test proposed by Karl Pearson [E. S. Pearson, Biometrika **30** (1938), 134–148] (the choice depending on the value of a certain parameter). Useful one-sample limits of Wilcoxon's [F. Wilcoxon, Biometrics **1** (1945), 80–83] (two-sample) test and the Brown-Mood [G. W. Brown and A. M. Mood, Proc. Second Berkeley Sympos. Math. Statist. and Prob., 1950, pp. 159–166, Univ. of California Press, Berkeley, Calif., 1951] median test are presented. Although the point is not developed in this paper, it may be remarked that the one-sample and two-sample forms of the Kolmogorov-Smirnov tests are similarly related, as the reader familiar with them can verify at once."

C. Hayashi (Tokyo)

Rogers, Gerald S. 5339

An application of a generalized gamma distribution.

Ann. Math. Statist. **35** (1964), 1368–1370.

Let $\{x_{i1}, \cdots, x_{in_i}\}$ $(i = 1, 2, \cdots, k;\ k \geq 2,\ n_i \geq 2)$ be random samples from stochastically independent Gaussian populations with unknown means μ_i and unknown variances σ_i^2. Let the hypothesis H_0 be $\sigma_1^2 = \cdots = \sigma_k^2$ and λ the corresponding likelihood ratio. The author derives the probability distribution for λ.

De Carolis, Linda Vittoria 5340

Su la regressione interamente lineare. (French, English, Spanish, and German summaries)

Giorn. Ist. Ital. Attuari **26** (1963), 118–139.

The author extends to n-dimensional random variables certain concepts earlier studied for the bivariate case by G. Pompilj [Industria (Milano) **1955**, 496–510; ibid. **1957**, 211–226; Fac. Sci. Statist. Demograf. Attuar. Ist. Statist. Ist. Calcolo Prob. Publ. No. 15 (1956); MR **20** #3586; ibid. No. 30 (1957); MR **21** #955]. One assumes throughout that moments of all orders exist and completely determine the distribution function, and that the covariance matrix is non-singular.

The regression of X_n on $X_1, \cdots, X_{n-1}$ is said to be pseudo-linear if the regression polynomials of all degrees coincide with one and the same hyperplane. G. Dall'Aglio [Rend. Mat. e Appl. (5) **15** (1956), 453–468; MR **19**, 69] showed that the linearity of $E(X_n \mid X_1, \cdots, X_{n-1})$ implies that the regression of X_n on $X_1, \cdots, X_{n-1}$ is pseudo-linear, but not the converse. Let $Y_1, \cdots, Y_n$ be any set of variates obtained from $X_1, \cdots, X_n$ by a non-singular affine transformation. If, for every such transformation, the regression of Y_n on $Y_1, \cdots, Y_{n-1}$ is linear or pseudo-linear, then one says that the regressions of the n-dimensional random variables $(X_1, \cdots, X_n)$ are entirely linear or entirely pseudo-linear, respectively.

The present author finds three sets of necessary and sufficient conditions for the regressions to be entirely pseudo-linear. Entirely pseudo-linear regression always

implies entirely linear regression, in contrast to the situation when "entirely" is dropped. If the distribution of $(X_1, \cdots, X_n)$ is absolutely continuous, their density has spherical symmetry about the mean when measured in the metric of the covariance matrix. The multivariate Student's t-distribution is an example of a distribution whose regressions are entirely linear.

Good, I. J. 5341

On the independence of quadratic expressions.

With an appendix by L. R. Welch.

J. Roy. Statist. Soc. Ser. B **25** (1963), 377–382.

Author's summary: "Let $y_1, y_2, \cdots$ be pairwise independent quadratic expressions in $\mathbf{x}$, not necessarily homogeneous, where $\mathbf{x}$ has a multinormal distribution. Then $y_1, y_2, \cdots$ are also mutually independent. Various conditions for independence are given. In the Appendix, it is shown that $\mathbf{x}$ is a linear transformation of a vector $\mathbf{z}$, where $\mathbf{z}$ has a spherically symmetric distribution, and where the y's depend on disjoint subsets of the components of $\mathbf{z}$."

Khatri, C. G. 5342

Further contributions to Wishartness and independence of second degree polynomials in normal vectors.

J. Indian Statist. Assoc. **1** (1963), 61–70.

Let $X = ((x_{ij}))_{p\times n}$ be normally distributed with $E(X) = \mu$ and $\operatorname{cov}(x_{ij}, x_{i'j'}) = v_{ii'}, w_{jj'}$, and let $V = ((v_{ii'}))_{p\times p}$ and $W = ((w_{jj'}))_{n\times n}$.

In the present paper, the author studies the conditions under which a second-degree polynomial in X has a Wishart distribution when the matrix W is singular. Finally, the author derives a condition for the stochastic independence of two such second-degree polynomials in X under a similar assumption. These results are some generalizations of the results of a previous paper [Ann. Math. Statist. **33** (1962), 1002–1007; MR **25** #4594].

R. G. Laha (Washington, D.C.)

Khatri, C. G. 5343

Joint estimation of the parameters of multivariate normal populations.

J. Indian Statist. Assoc. **1** (1963), 125–133.

In the present paper, the author extends a method of estimation suggested by Fields, Kramer and Clunies-Ross [J. Amer. Statist. Assoc. **57** (1962), 446–454; MR **26** #4438] to the case of parameters of multivariate normal populations having equal mean vectors but different covariance matrices. The author illustrates his method by an example.

R. G. Laha (Washington, D.C.)

Meredith, William 5344

Notes on factorial invariance.

Psychometrika **29** (1964), 177–185.

Author's summary: "Lawley's selection theorem is applied to subpopulations derived from a parent in which the classical factor model holds for a specified set of variables. The results show that there exists an invariant factor pattern matrix that describes the regression of observed on factor variables in every subpopulation derivable by selection from the parent, given that selection does not occur directly on the observable variables and does not reduce the rank of the system. However, such a factor pattern matrix is not unique, which in turn implies that if a simple structure factor pattern matrix can be satisfactorily determined in one such subpopulation the same simple structure can be found in any subpopulation derivable by selection. The implications of these results for 'parallel proportional profiles' and 'factor matching' techniques are discussed.

P. S. Dwyer (Ann Arbor, Mich.)

Meredith, William 5345

Rotation to achieve factorial invariance.

Psychometrika **29** (1964), 187–206.

Author's summary: "Under certain conditions it is reasonable to assume that the same factor pattern matrix will describe the regression of observed on factor scores in different populations. However, ordinary factoring procedures will not reveal in general the existence of such a factor pattern matrix. Two procedures for rotating any number of factor pattern matrices based on different populations to conform to a single 'best fitting' factor pattern matrix are developed in this paper. It is assumed that the same number of factors have been determined for each population. Both procedures will yield oblique results in the various populations. The procedures are illustrated with data taken from the 1939 Holzinger-Swineford monograph. Four groups of individuals are utilized."

P. S. Dwyer (Ann Arbor, Mich.)

Cox, D. R. 5346

Some applications of exponential ordered scores.

J. Roy. Statist. Soc. Ser. B **26** (1964), 103–110.

Author's summary: "There are simple standard tests for the comparison of samples assumed to arise from exponential distributions, but the properties of these tests are known to depend severely on the assumption of exponential form. However, the observations can sometimes usefully be ranked, and then replaced by the corresponding expected values of order statistics in sampling the unit exponential distribution before calculating the appropriate test statistic. Some special tests of this type are examined. The procedure is analogous to the use of Fisher and Yates's scores in normal theory. Savage [Ann. Math. Statist. **27** (1956), 590–615; MR **18**, 243] gave the test of this type for comparing two samples, in the course of a general study of rank tests for the two-sample problem."

Switzer, Paul 5347

Significance probability bounds for rank orderings.

Ann. Math. Statist. **35** (1964), 891–894.

Author's summary: "The problem of two-sample rank order tests is examined from the point of view of I. R. Savage [same Ann. **27** (1956), 590–615; MR **18**, 243; ibid. **28** (1957), 968–977; MR **20** #396; ibid. **30** (1959), 1018–1023; MR **22** #289; Tech. Rep. No. 15, Univ. Minnesota (1962)]. Under suitable restriction of the class of alternatives some rank orderings are always more probable than (dominated by) others. Hence, if the rejection region of a test contains the ordering c, it must also contain all orderings dominated by c if the test is to be admissible. Thus, by counting the number of orderings dominated by c we

arrive at a lower bound for the size of an admissible test which rejects when c is observed. Similar reasoning leads to an upper bound. The counting is achieved by putting all orderings in one-one correspondence with paths on a grid; all paths lying below or along the observed path correspond to the orderings dominated by the observed ordering. An expression for this number of paths is obtained. This expression is used to compute significance bounds for a pair of illustrative examples. Finally, the main result for the two-sample problem is extended to obtain upper and lower bounds for a one-sample problem."

Lindley, D. V. 5348

★Introduction to probability and statistics from a Bayesian viewpoint. Part I: Probability.

Cambridge University Press, New York, 1965. xi + 259 *pp*. $6.00.

This book is an introduction, at a fairly elementary level, to the mathematics of probability. It is designed to lead into a Bayesian treatment of statistical inference, but this fact rarely manifests itself, and the development of the theory, though often refreshing and stimulating, is basically orthodox. It is a book for the student with some mathematical equipment, taking for granted for instance the elementary properties of limits, integrals, and differential equations, but stopping well short of measure theory. The level of rigour is lower than a cursory glance would suggest, difficulties whose resolution would require more mathematics than the reader is likely to have being skilfully ignored.

The first chapter contains a careful discussion of probability as limiting frequency, and uses this to motivate an informal discussion of the axioms. Probability is treated throughout as a function $p(A|B)$ of two arguments, the usual axioms being supplemented by the Rényi axiom $p(C|AB)p(A|B)=p(AC|B)$. After giving the simplest consequences of the axioms, the author discusses the idea of probability as degree of belief (this is really the only important concession to the inclusion of the name of Bayes in the title).

The remainder of the book consists of three chapters, dealing respectively with one random variable, several variables, and stochastic processes. Expectation is defined separately for discrete and continuous distributions, the use of Stieltjes integration being avoided. The usual elementary distributions are discussed, and the Poisson process makes a welcome entry quite early and is used to introduce the Poisson, exponential, and Γ distributions. The simple random walk also comes early in the book, and its diffusion approximation is derived heuristically to illustrate the central limit theorem. One of the attractive features of the author's presentation is the way in which the rather dull manipulations of probability distributions are shot through with applications to the simple stochastic processes which are perhaps the most exciting aspects of probability theory at this level.

The usual results about characteristic functions and sums of random variables are discussed, the deeper ones being left unproved, and there is a good treatment of functions (linear and otherwise) of several random variables. The book ends with an account of processes of birth-and-death type, simple queueing processes, renewal theory (with a glaringly incomplete proof of the Erdős-Feller-Pollard theorem), and Markov chains (discrete in space and time).

Each chapter ends with a good set of exercises, taken largely from examinations set in English universities.

There are, of course, many introductory texts on probability theory. This one has a flavour of its own, which should ensure it a distinctive place in the elementary literature.

J. F. C. Kingman (Cambridge, England)

Lindley, D. V. 5349

★Introduction to probability and statistics from a Bayesian viewpoint. Part II: Inference.

Cambridge University Press, New York, 1965. xiii + 292 *pp*. $6.50.

This volume, which is written on the same general level as the first [see #5348 above], is perhaps the first elementary account of statistical inference developed entirely from a Bayesian (but not decision-theoretic) point of view. Its starting point is the idea of probability as degree-of-belief which made a brief appearance in Part I, and which is taken for granted in this part.

The emphasis throughout is very much on the normal distribution. Thus the first chapter begins by computing the posterior distribution of the mean of a normal distribution with known variance, the prior being assumed normal. This result is extended, elaborated, and interpreted at some length. The case of unknown variance is treated, the χ^2- and t-distributions making their appearance as posterior distributions. A pleasantly simple discussion of sufficiency (including the introduction of the exponential family) leads to an account of the likelihood principle and of significance tests (in the Bayesian sense).

The second chapter pursues the analysis further to deal with the comparison of several normal populations. The F-distribution appears as the posterior distribution of the ratio of two estimates of variance, when means and logarithms of variance have uniform prior distributions. Under the same conditions the Behrens-Fisher problem is easily disposed of, and the chapter ends with a brief introductory discussion of the analysis of variance.

The third chapter is headed "Approximate Methods", which title is held to include maximum likelihood (in large samples the posterior distribution is concentrated about the maximum likelihood estimate), the normal approximation to binomial and Poisson distributions, and the χ^2 technique for goodness-of-fit tests and contingency tables. The final chapter deals with least squares methods, and gives the Bayesian approach to regression and the general linear hypothesis.

In practice the usefulness of this book (Part II, not Part I) will be limited by its Bayesian approach, which would cause complete confusion in the mind of an undergraduate learning statistics from a more "classical" standpoint. Where, however, the Bayesian has driven the classical approach from the field of undergraduate teaching, this book will provide a first-rate introductory text on the problems of inference.

Owen, D. B.; Craswell, K. J.; Hanson, D. L. 5350

Nonparametric upper confidence bounds for $\Pr\{Y<X\}$ and confidence limits for $\Pr\{Y<X\}$ when X and Y are normal.

J. Amer. Statist. Assoc. 59 (1964), 906–924.

The authors extend the Birnbaum-McCarty confidence bounds (based on the Wilcoxon statistic) to the case of possibly discontinuous observations. Then, of course, the cases $\Pr(Y<X)$ and $\Pr(Y\leq X)$ must be distinguished. The other parts of the paper deal with normal bivariate samples in situations classified as follows: (i) variances and covariance known; (ii) independence and equal variances, but $\sigma=\sigma_1=\sigma_2$ unknown; (iii) variances and covariance unknown. Six tables are provided. *J. Hájek* (Prague)

Sukhatme, Shashikala 5351

Some non-parametric tests for location and scale parameters in a mixed model of discrete and continuous variables.

J. Indian Soc. Agric. Statist. **14** (1962), 121–137.

The author considers rank statistics used in the median test, the Wilcoxon test, the Mood test, etc. He assumes that the size of the first sample, n, is a random variable with binomial distribution, and computes the overall distribution of the above statistics, accounting for the variability of n. Then he suggests basing the critical values of corresponding tests on these overall distributions. He shows that the tests so modified have smaller asymptotic efficiency than the tests where we regard n as a constant and do not utilize the information about its random origin.

J. Hájek (Prague)

Willke, T. A. 5352

General application of Youden's rank sum test for outliers and tables of one-sided percentage points.

J. Res. Nat. Bur. Standards Sect. B **68B** (1964), 55–58.

From the author's summary: "The rank sum test for outliers advanced by W. J. Youden provides a method for detecting if the measurement distribution of any one of a group of objects has a mean significantly different from the rest. This paper discusses a more general application of the rank sum procedure which permits a similar test on other parameters, such as the variance, with the same tables. Tables of the critical values of the extreme rank sum and the corresponding significance levels for one-sided tests are given in this paper to supplement similar tables for two-sided tests already published."

J. Hájek (Prague)

Nair, C. Ramankutty 5353

A new class of designs.

J. Amer. Statist. Assoc. **59** (1964), 817–833.

The author defines an association scheme which relaxes the condition of symmetry of association between two treatments as given by Bose and Shimamoto [same J. **47** (1952), 151–184; MR **14**, 67]. A careful reader who goes through this paper is bound to get confused with the results, as the paper lacks consistency and contains misstatements and inadequate proofs. The author, in many places, assumes certain properties of his association scheme which are neither contained in his definition nor are consequences of the definition. The model assumed by the author does not point out, in any way, the necessity of introducing his new class of designs.

Natrella, Mary Gibbons 5354

★Experimental statistics.

National Bureau of Standards, Handbook 91.

Superintendent of Documents, U.S. Government Printing Office, Washington, D.C., 1963. xxix + 522 *pp.* (*not consecutively paged*) \$4.25.

This Handbook contains, in a single volume, a collection of statistical procedures that are useful in the design, development, and testing of materials, the evaluation of equipment performance, and the conduct and interpretation of scientific experiments.

The Handbook is presented in five sections: Section 1, Basic concepts and analysis of measurement data; Section 2, Analysis of enumerative and classificatory data; Section 3, Planning and analysis of comparative experiments; Section 4, Special topics, deals with a number of important but as yet nonstandard statistical techniques, and various other special topics; and Section 5 contains the mathematical tables needed for application of the procedures given in the first four sections. These are followed by an index covering all five sections.

Bhat, B. R. 5355

Bayes solution of sequential decision problem for Markov dependent observations.

Ann. Math. Statist. **35** (1964), 1656–1662.

From the author's summary: "After discussing the sequential decision problem in the general case and its Bayes solution as given by Wald, LeCam and others . . ., we give the integral equation satisfied by the Bayes risk. . . . We specialise to Markov dependent observations and . . . give an illustrative example."

Bedingte Strategien in der Spieltheorie: Existenzsätze und Anwendung auf statistische Entscheidungsfunktionen.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 35–43. *Publ. House Czech. Acad. Sci., Prague*, 1964.

The results are proved among strategies with a given bound on their risk functions, using compactness and lower-semicontinuity conditions similar to those of LeCam [Ann. Math. Statist. **26** (1955), 69–81; MR **16**, 730].

J. Kiefer (Ithaca, N.Y.)

Connor, W. S. 5357

The conditional distribution of sets of tests on a system simulated from tests on its components.

Ann. Math. Statist. **34** (1963), 1585–1587.

Consider a system which is made up of components in such a way that failure of any component causes the failure of the system, and the system cannot fail unless some component fails. A trial for the system is simulated by drawing at random a result for each component. If all component results are successes, the system trial is a success; if not, the system trial is a failure. The process is continued without replacement of component results until n^* system trials have been generated.

In this note the conditional distribution of S, the

number of successful system trials, given n_{i1}, the number of successes in the n_i trials for the ith component $(i=1, 2, \cdots, k)$, has been derived.

The expected value of S is shown to be equal to the product of the $\hat{p}_i$'s, where $\hat{p}_i = n_{i1}/n_i$, the estimated reliability of the ith component. *A. K. Gayen* (Kharagpur)

Hudimoto, Hirosi 5358

On the classification. I. The case of two populations. (Japanese. English summary)

Proc. Inst. Statist. Math. 11 (1963/64), 31–38.

The author considers the use of Mann-Whitney statistics for classifying a sample into either of two populations π_1 and π_2. The distribution functions $F_1(x^{(1)})$ of π_1 and $F_2(x^{(2)})$ of π_2 are known, and $(X_1, \cdots, X_n)$ is a random sample of size n from π_1 or π_2. He uses the statistics $\hat{p}_1 = (1/n)\sum_{k=1}^{n} F_1(X_k)$ and $\hat{p}_2 = 1-(1/n)\sum_{k=1}^{n} F_2(X_k)$, where $\hat{p}_1$ is an unbiased estimate of $\int_{-\infty}^{\infty} F_1(t)\,dF_2(t)$ when $(X_1, \cdots, X_n)$ is a sample from π_2 and an estimate of $\frac{1}{2}$ when $(X_1, \cdots, X_n)$ is a sample from π_1, $\hat{p}_2$ is an unbiased estimate of $\frac{1}{2}$ when $(X_1, \cdots, X_n)$ is a sample from π_2 and an estimate of $\int_{-\infty}^{\infty} F_1(t)\,dF_2(t)$ when $(X_1, \cdots, X_n)$ is a sample from π_1.

The author presents the following classification procedure: If $F_1(t) > F_2(t)$ for all t, classify $(X_1, \cdots, X_n)$ into π_1 or π_2 according as $\hat{p}_1 < \hat{p}_2$ or $\hat{p}_1 > \hat{p}_2$, respectively. In this case, he gives an evaluation of the success rate and then shows that the method is also applicable for the non-parametric case where these distribution functions are estimated from samples. *C. Hayashi* (Tokyo)

Kincaid, W. M. 5359

The combination of $2 \times m$ contingency tables.

Biometrics 18 (1962), 224–228.

It is supposed that at each of k levels $(x_1, \cdots, x_k)$ of a stimulus x and for each of m categories of a qualitative factor y, a fixed number n of individuals are assayed in respect of a yes/no response. It is noted that the hypothesis that the stimulus-response pattern is the same in all y-categories may be tested by adding the appropriate chi-squares of the $2 \times m$ contingency tables for each level of stimulus but that the resulting test is not particularly sensitive to systematic differences of stimulus-response pattern as between the different y-categories. It is suggested that a more sensitive test may be obtained by testing the total number of favourable responses in each y-category for heterogeneity. Appropriate formulae are given for this, and the extension to cases where different numbers of individuals are assayed in each (x, y) category. A rather inconclusive discussion in general terms is given of the circumstances where the corresponding test statistic may be considered to have, approximately, a chi-squared distribution under the null hypothesis. There is no mention of the standard methods for comparison between stimulus-response curves which, on the face of it, would seem to be optimal in these circumstances [see, e.g., D. J. Finney, *Statistical method in biological assay*, Hafner, New York, 1952]. *D. E. Barton* (London)

Walker, A. M. 5360

Large-sample estimation of parameters for autoregressive processes with moving-average residuals.

Biometrika 49 (1962), 117–131.

The author is concerned with the maximum likelihood estimation of parameters in the model

$$\sum_{j=0}^{p} \alpha_j(x_{t-j}-\mu) = \sum_{k=0}^{q} \beta_k \varepsilon_{t-k},$$

where the ε_t are NID$(0, \sigma^2)$, and the α_j are such that the x_t process is stationary. He generalises the methods of a previous paper [Biometrika 48 (1961), 343–357; MR 25 #728] to this situation.

The quantities $\alpha_1, \alpha_2, \cdots, \alpha_p$; $\rho_1, \rho_2, \cdots, \rho_q$ are taken as the set of parameters to be estimated (ρ_s being the auto-correlation coefficient of $\log s$), and it is shown that estimation equations can be written asymptotically in the form

$$\hat{\rho}_i = \hat{\bar{r}}_i \qquad (1 \leqq i \leqq q),$$

$$\sum_{j=0}^{p} \hat{\alpha}_j \hat{\bar{r}}_{i-j} = 0 \qquad (q+1 \leqq i \leqq q+p),$$

where $\bar{r}_i$ is the residual obtained by subtracting from the ith sample auto-correlation coefficient its asymptotic regression on the set of variables $(S_{q+p+1}, S_{q+p+2}, \cdots, S_k)$ and $S_l = \sum_{i,j=0}^{p} \alpha_i \alpha_j r_{l-i-j}$.

The author demonstrates a convenient iterative procedure for solution of the estimation equations and determines several asymptotic properties of the estimates. *P. Whittle* (Manchester)

Hannan, E. J. 5361

The estimation of seasonal variation in economic time series.

J. Amer. Statist. Assoc. 58 (1963), 31–44.

The author assumes the usual additive model $y_t = p_t + s_t + x_t$, where p_t, s_t and x_t represent "trend", "seasonal trend" and "stationary component", respectively. He is principally concerned with the effect of trend-removing operators upon the seasonal component, and shows that the effect of such operations can be allowed for, so that the seasonal component of the original series can be deduced from that estimated for the trend-adjusted series. The computation is reduced to a routine, which is illustrated numerically. The estimation of a slowly evolving seasonal is also considered. *P. Whittle* (Manchester)

Herbst, Laurence J. 5362

Periodogram analysis and variance fluctuations.

J. Roy. Statist. Soc. Ser. B 25 (1963), 442–450.

Author's summary: "Two problems in the subject of time-series analysis are considered: (A) the effect of fluctuating variances on the periodogram of a set of independent Gaussian data with zero means; (B) the possibility of using the periodogram of squares of independent Gaussian data with zero means as a tool in the Fourier analysis of the variances of the data. The basic effect of fluctuating variances on the periodogram is to introduce correlations (expressible in terms of the Fourier coefficients of the variance) which do not decrease as the sample size increases. The periodogram of squares of independent Gaussian data with zero means is shown to be an appropriate tool in the Fourier analysis of the variances."

Comer, John P., Jr. 5363

Some stochastic approximation procedures for use in process control.

Ann. Math. Statist. **35** (1964), 1136–1146.

Let M be a measurable function on the real line. Assume that a chemical process, for instance, can be described as $Y_n = M(X_n) + Z_n$, $n \geq 1$, where X_n, Y_n, Z_n are random variables. Let Y_0 be a given real number. The random variables X_n, $n \geq 1$, describe a control procedure which is chosen in such a way as to keep $E(Y_n - Y_0)^2$ small. X_{n+1} may depend on the prior values X_i, Y_i, $1 \leq i \leq n$. Let $A < B$ and $0 < g < h$. Suppose that

$$g \leq (M(x) - M(x'))/(x - x') \leq h \quad \text{for} \quad A \leq x < x' \leq B.$$

Furthermore, assume that there exists a θ in the interval $[A, B]$ such that $M(\theta) = Y_0$. A control procedure is defined which is very similar to the Robbins-Monro standard approximation procedure [same Ann. **22** (1951), 400–407; MR **13**, 144]. Let

$$\begin{aligned} i(x) &= A, \qquad x < A, \\ &= x, \qquad A \leq x \leq B, \\ &= B, \qquad B > x. \end{aligned}$$

Specify a value of X_1 in $[A, B]$ and define $X_{n+1} = i(X_n - a_n(Y_n - Y_0))$, $n \geq 1$, where a_n is a sequence of positive numbers satisfying $\lim_{n\to\infty} a_n = a$, $\sum_{n=1}^{\infty} a_n = \infty$. Under the further condition $0 \leq a < 1/h$ and

$$E\{[E(Z_n | Z_1, \cdots, Z_{n-m})]^2\} = \sigma_m^{\ 2} \to 0 \quad \text{as} \quad m \to \infty,$$

upper bounds for

$$\limsup_{n\to\infty} E(X_n - \theta)^2 \quad \text{and} \quad \limsup_{n\to\infty} E(Y_n - Z_n)^2$$

are derived which converge to 0 as a goes to 0. Some more results of a similar kind are mentioned without proofs. For them the author refers to his Doctoral Dissertation [Columbia Univ., New York, 1962].

Generalized cumulant expansion method.

J. Phys. Soc. Japan **17** (1962), 1100–1120.

Author's summary: "The moment generating function of a set of stochastic variables defines the cumulants or the semi-invariants and the cumulant function. It is possible, simply by formal properties of exponential functions, to generalize to a great extent the concepts of cumulants and cumulant function. The stochastic variables to be considered need not be ordinary c-numbers but they may be q-numbers such as used in quantum mechanics. The exponential function which defines a moment generating function may be any kind of generalized exponential, for example, an ordered exponential with a certain prescription for ordering q-number variables. The definition of average may be greatly generalized as far as the condition is fulfilled that the average of unity is unity. After statements of a few basic theorems, these generalizations are discussed here with certain examples of application. This generalized cumulant expansion provides us with a point of view from which many existent methods in quantum mechanics and statistical mechanics can be unified."

The contributions in this volume are divided into three main sections: Numerical methods and applied mathematics (Part I); Digital computers (Part II); Analog computers (Part III). The longer papers in Part I will be reviewed or listed individually.

Frank, Evelyn 5366

Newton's formula and approximants of continued fraction expansions.

Univ. Lisboa Revista Fac. Ci. A (2) **10** (1963), 75–89.

The present paper supplements the author's earlier work [Numer. Math. **4** (1962), 85–95; MR **25** #3603; ibid. **4** (1962), 303–309; MR **26** #2765], which generalised results of J. Mikusiński and the reviewer [Mikusiński, Ann. Polon. Math. **1** (1954), 184–194; MR **15**, 954; Sharma, ibid. **6** (1959), 295–300; MR **21** #5621]. Let $\sqrt{(C+L)}$ be a binomial quadratic surd (C, L rational, $C > 0$) with the continued fraction expansion of period p. Consider the extended Newton's formula

$$(*) \qquad x_n = \frac{x_k \cdot x_l + C - L^2}{x_k + x_l - 2L}, \qquad n > k, n > l,$$

and let A_r/B_r denote the rth approximant of the continued fraction expansion. The author shows that if in (*) x_k and x_l are the kth and lth approximants of the continued fraction, then x_n is, in general, a mixed approximant $(\alpha_r A_r + \alpha_{r-1} A_{r-1})/(\beta_r B_r + \beta_{r-1} B_{r-1})$. Explicit forms of α_r, β_r are obtained. The case for symmetric regular periodic continued fraction expansions is also considered.

A. Sharma (Calgary, Alta.)

Hoel, P. G.; Levine, A. 5367

Optimal spacing and weighting in polynomial prediction.

Ann. Math. Statist. **35** (1964), 1553–1560.

The problem is the determination of observation points in the interval $[-1, 1]$, and the proportion of observations at each point, in order to minimize the variance of the predicted value of a polynomial regression curve of degree k at the specified point, x, beyond the interval. The results indicate that the desired $k+1$ observation points are given by the Chebyshev points, $x_i = -\cos i\pi/k$, $i = 0, 1, \cdots, k$, and that the number of observations should be proportional to the absolute value of the Lagrange polynomial. This Chebyshev solution becomes the minimax solution for the interval $(-1, t)$ if $t > t_1 > 1$ and t_1 satisfies a certain equation. Under the assumption of normality, this solution can be used to construct a confidence bound (for the polynomial curve) which possesses minimum width at x.

P. S. Dwyer (Ann Arbor, Mich.)

Podolsky, Boris; Denman, Harry H. 5368

Conditions on minimization criteria for smoothing.

Math. Comp. **18** (1964), 441–448.

Given a set of data points $\{Y_i(x_i)\}$, $i=1, 2, 3, \cdots, n$, one often seeks the "smoothest" curve $y(x)$ passing through or near the points; the criterion for smoothness is that the integral of some function $f(y, y', y'')$ be a minimum. However, the choice of units and scale are often governed by circumstances having little to do with the intrinsic mathematics of the situation. Consequently, the smoothness criterion should be invariant under change of scale or shift of origin.

The authors find that a necessary and sufficient condition that the smoothest curve $y(x)$ become $ay+b$ when Y_i is replaced by aY_i+b is that f be of the form

$$f = W(y', y'') + \partial Q(y, y', x)/\partial x,$$

where W is a homogeneous function of y' and y'', not linear in y''. *W. Langlois* (San Jose, Calif.)

Ul'm, S. 5369

A majorant principle and the method of secants. (Russian. Estonian and English summaries)

Eesti NSV Tead. Akad. Toimetised Füüs.-Mat. Tehn.-tead. Seer. **13** (1964), 217–227.

Author's summary: "Using the principle of majorants, some theorems on the convergence of the secant method are proved in linear normed spaces. The results of J. W. Schmidt [Z. Angew. Math. Mech. **41** (1961), Sonderheft, T61–T63; ibid. **43** (1963), 1–8; MR **26** #5442] and A. S. Sergeev [Sibirsk. Mat. Ž. **2** (1961), 282–289; MR **24** #A377] are made more precise. The theorems proved may also be considered as generalizations of the theorems on the convergence of Newton's method."

Fil'čakova, V. P. 5370

On a numerical method for the conformal mapping of exterior simply connected domains. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 1127–1132.

Author's summary: "An effective numerical method is proposed for conformal mapping of the exterior of a unit circle into the exterior of a given simply connected domain. It is based on trigonometrical interpolation. The method makes it possible to find the coefficients of the mapping polynomial with any preassigned degree of accuracy. The contour may be given analytically, graphically or tabularly."

Oettli, W.; Prager, W. 5371

Compatibility of approximate solution of linear equations with given error bounds for coefficients and right-hand sides.

Numer. Math. **6** (1964), 405–409.

Given an approximate solution x^0 to the linear system $Ax=b$, and assigned tolerances $\Delta A \geq 0$ and $\Delta b \geq 0$, it is asked under what circumstances there exist δA and δb, with $|\delta A| \leq \Delta A$, $|\delta b| \leq \Delta b$, such that $(A+\delta A)x^0 = b+\delta b$ exactly (absolute value signs and inequalities are to be interpreted elementwise). The argument is unnecessarily involved, since if $r = Ax^0 - b$, then it is necessary and sufficient that $|r| \leq \Delta b + (\Delta A)|x^0|$. The question is relevant to J. H. Wilkinson's backward error analysis.

A. S. Householder (Oak Ridge, Tenn.)

Balogh, L.; Békésy, A.; Fáy, Gy. 5372

Use of a matrix factorization method to some problems of dimensional analysis. (German, French, and Russian summaries)

Acta Tech. Acad. Sci. Hungar. **48** (1964), 241–251.

Authors' summary: "An algorithm is given for determining criteria when using the tools of dimensional analysis. The algorithm is based on a paper by E. Egerváry [Z. Angew. Math. Mech. **35** (1955), 111–118; MR **16**, 1156]. The method presented is, in fact, a modified version of an earlier method for decomposing matrices into dyads. Examples."

La Budde, C. Donald 5373a

Two new classes of algorithms for finding the eigenvalues and eigenvectors of real symmetric matrices.

J. Assoc. Comput. Mach. **11** (1964), 53–58.

Kaiser, Henry F. 5373b

A method for determining eigenvalues.

J. Soc. Indust. Appl. Math. **12** (1964), 238–248.

The methods of both papers use a sequence of unitary transformations of a given hermitian matrix such that the (1, 1)-element is monotonically increasing (or decreasing). They are, in fact, closely related. Following Householder [*The theory of matrices in numerical analysis*, p. 201, problem 17, Blaisdell, New York, 1964], a unified treatment can be given as follows: Let a hermitian matrix be $(1, n-1)$-partitioned in the form $A = \begin{pmatrix} \beta & b^H \\ b & B \end{pmatrix}$. Let u be a unit vector of dimension $n-1$. The 2-by-2 matrix $\bar{A} = \begin{pmatrix} 1 & 0 \\ 0 & u \end{pmatrix} A \begin{pmatrix} 1 & 0 \\ 0 & u^H \end{pmatrix} = \begin{pmatrix} \beta & b^H u \\ u^H b & u^H B u \end{pmatrix}$ has a larger root $\bar{\lambda}_1$, which is greater than β, provided $b^H u \neq 0$ (and a smaller root $\bar{\lambda}_2$, which is less than β), $\beta < \bar{\lambda}_1 \leq \lambda_1(A)$. Therefore, there exists a unit vector r and a number β' such that $\beta < \beta' = r^H \bar{A} r \leq \bar{\lambda}_1 \leq \lambda_1(A)$. Selecting such an r and forming $v = \begin{pmatrix} 1 & 0 \\ 0 & u \end{pmatrix} r$, we obtain $\beta' = v^H A v$. Thus, if a unitary matrix V contains such a v as its first column, the (1, 1)-element of the transformed matrix $A^{(1)} = V^H A V$ equals β', $\beta' > \beta$.

The choice of u and r is at our disposal and also the computational process for forming $A^{(1)}$ from A, that is, the selection of V. Kaiser economizes, by the choice of u, the computational work involved in forming $b^H u$ and $u^H B u$, by defining $u_i = \operatorname{sign} b_i/\sqrt{(n-1)}$. La Budde follows the tactical advantage of maximizing $|b^H u|$ by choosing $u = b/\|b\|$. Kaiser chooses for r the eigenvector of $\bar{A}$ belonging to $\bar{\lambda}_1$ (or to $\bar{\lambda}_2$). La Budde does so, too, but mentions also that convergence holds even if this absolute maximum for β' is not reached, and considers even more economical choices of r. Kaiser's computation is straightforward as outlined above; $\bar{A}$, r, v are constructed, V is a single elementary Householder matrix (hermitian, unitary), which is uniquely determined from v, which is its first column, $V = I - (e_1 - v)(e_1 - v)^H/(1 - e_1{}^T v)$, where $e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$

(in order to ensure stability, the sign of V should be chosen such that $e_1{}^T v<0$). La Budde performs the calculation in two steps. In a first step, with u proportional to b, he applies the usual Householder transformation $\begin{pmatrix}1 & 0\\ 0 & Q\end{pmatrix} A \begin{pmatrix}1 & 0\\ 0 & Q\end{pmatrix} = A^*$ which annihilates $b_{13}, b_{14}, \cdots, b_{1n}$. (By using the representation

$$Q = I+(u-\ell e)(u-\ell e)^H/\ell\cdot(e^H u-\ell),$$

where $\|e\|=1$ (in fact, e is the second axis vector) and

$$\ell = -\|u\| \quad \text{if } e^H u \geq 0,$$
$$\;\;= +\|u\| \quad \text{if } e^H u < 0,$$

only one square root is to be formed; see, for example, the reviewer [J. Soc. Indust. Appl. Math. 7 (1959), 107–113; MR 20 #6778].) Since $Qu=\ell e$ and $Qe=u/\ell$, $\begin{pmatrix}1 & 0\\ 0 & e^H\end{pmatrix} A^* \begin{pmatrix}1 & 0\\ 0 & e\end{pmatrix} = \tilde{A}$. Next, he performs a Jacobi rotation of the two axes $\begin{pmatrix}1\\ 0\end{pmatrix}$, $\begin{pmatrix}0\\ e\end{pmatrix}$ on A^*, which gives $A^{(1)}$.

Limited experience shows that the Kaiser-La Budde method may well compare favorably in convergence speed and computational work with the best-known methods for determining eigenvalues, especially if only a few eigenvalues are wanted. *F. L. Bauer* (Munich)

Martin, D. W.; Tee, G. J. 5374

Iterative methods for linear equations with symmetric positive definite matrix.

Comput. J. 4 (1961/62), 242–254.

Authors' summary: "The salient features of iterative methods commonly encountered in the literature are described, to provide a self-contained résumé of recent developments and to serve as an introduction to detailed study of particular topics. The discussion is organized under two main headings: (i) Stationary methods and their linear acceleration; (ii) Gradient methods and kernel polynomials. A tentative evaluation of the various methods is made on the basis of recent experiments."

Ortega, James M. 5375

Generation of test matrices by similarity transformations.

Comm. ACM 7 (1964), 377–378.

Author's summary: "A method for obtaining test matrices with a prescribed distribution of characteristic roots is given. The process consists of using particularly simple similarity transformations to generate full matrices from canonical foms. The matrices generated also have known characteristic vectors, inverses and determinants."

Stojaković, M. 5376

Inversion of matrices appearing in the application of the method of least squares. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. 4 (1964), 911–915.

More specifically, this has to do with fitting polynomials by least squares. The matrix of coefficients of the equations to be solved can be written $W_n=\sum X_i X_i'$, where $X_i'=(1, x_i, x_i^2, \cdots, x_i^m)$. In particular, W_{m+1} is the product of two Vandermonde matrices, and the author has treated the inversion of Vandermonde matrices in a previous paper [C. R. Acad. Sci. Paris 246 (1958), 1133–1135; MR 19, 1079]. He now proposes to use a recursion

$$W_{n-1}^{-1} = W_n^{-1}-g_n^{-1}W_n^{-1}X_n X_n' W_n^{-1}$$

[see, e.g., the reviewer's *Principles of numerical analysis* p. 79, McGraw-Hill, New York, 1953; MR 15, 470]. *A. S. Householder* (Oak Ridge, Tenn.)

Teterev, A. G. 5377

Positive matrix invertibility and the method of monotone approximations. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika 1964, no. 3 (40), 143–150.

Some conditions are given on a matrix A that guarantee that all elements of A^{-1} are positive (positive invertibility). Counterexamples are given to show the sharpness of the conditions, and finally the notion of positive invertibility is generalized in an interesting way. Let N be the set $\{1, \cdots, n\}$; let I, J be subsets of N. Let X_I be the set of vectors $x=(x_1, \cdots, x_n)$ such that $x_i>0$ for $i\in I$, $x_i\leq 0$ for $i\notin I$. The matrix A is of type (I, J) if $AX_I\subset X_J$. The type (N, N) corresponds to positive invertibility. An example is the matrix (a_{ij}) with dominant diagonal and $a_{ii}>0$, $a_{ij}\leq 0$ $(j\neq i)$.

Finally, the author gives conditions for the monotone convergence of (upper and lower) approximations to solutions of nonlinear sets of equations [see L. Collatz and J. Schröder, Numer. Math. 1 (1959), 61–72; MR 21 #1688]. The excessively condensed style partly conceals a logical, attractive theory. *J. L. Brenner* (Palo Alto, Calif.)

Ting, Thomas C. T. 5378

A method of solving a system of linear equations whose coefficients form a tridiagonal matrix.

Quart. Appl. Math. 22 (1964), 105–116.

The author describes a method of solving a system of equations $Ax=d$ when A is tri-diagonal. It is based on the decompositions $A=L_1U_1$ and $A=U_2L_2$, where L_1 is lower-triangular, U_1 is unit upper-triangular, U_2 is upper-triangular and L_2 is unit upper-triangular. It is shown that $A=L_1+U_2-W$, where W is a diagonal matrix. Hence $W=L_1+U_2-A=A(U_1{}^{-1}+L_2{}^{-1}-I)$, showing that $A^{-1}=(U_1{}^{-1}+L_2{}^{-1}-I)W^{-1}$. The matrices U_1 and L_2 have only one super-diagonal line and sub-diagonal line respectively; the matrices $U_1{}^{-1}$ and $L_2{}^{-1}$ are therefore not computed explicitly. The method has advantages when solutions corresponding to several right-hand sides d are required. *James H. Wilkinson* (Teddington)

Kizner, William 5379

A numerical method for finding solutions of nonlinear equations.

J. Soc. Indust. Appl. Math. 12 (1964), 424–428.

As the title states, this paper presents a numerical method for finding solutions of nonlinear equations. If z_1 is an approximation for a root z of $f(z)=0$, then

$$z = z_1+\int_{f(z_1)}^{0} \frac{dz}{df}\,df.$$

The described method obtains a new approximation for z by performing the indicated integration numerically.

using the Runge-Kutta method. It is proved that under certain conditions, the order of convergence of the method is 5. That is, if e_k is the error after the kth step, then e_{k+1}/e_k^5 tends to a constant as $k\to\infty$.

Making certain reasonable assumptions, one finds that, asymptotically, the accuracy gained per unit amount of work is about the same for this method as for Newton's method. The author states, however, that in practice this method yields better results in the initial step which starts with a crude approximate root. He suggests using one step of this method followed by the use of Newton's method.

The method is easily extended for obtaining solutions of systems of equations. No numerical results are given.

E. R. Hansen (Palo Alto, Calif.)

Lancaster, P. 5380

Convergence of the Newton-Raphson method for arbitrary polynomials.

Math. Gaz. **48** (1964), 291–295.

The author gives an elementary account "of the convergence properties of the sequence of iterates obtained by applying the Newton-Raphson process to an arbitrary polynomial". In order to keep the treatment elementary, it is necessary to confine attention to polynomials, but the coefficients may take complex values; furthermore, it is possible to deal with multiple roots. Although the results obtained are not original, the methods used to derive them are novel.

Barrucand, Pierre 5381

Quadratures numériques, fonctions elliptiques et facteur de convergence.

C. R. Acad. Sci. Paris **258** (1964), 2742–2744.

This note gives an accurate procedure for the numerical evaluation of integrals of the form

$$\int_0^1 F(x)(1-x^2)^{-1/2}\,dx$$

when $F(x)$ is even, analytic and has no singularities on $[-1,+1]$. The integration formula is a weighted sum involving elliptic functions.

R. C. MacCamy (Pittsburgh, Pa.)

Ermakov, S. M. 5382

Stochastic quadratures of increased accuracy. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 550–554.

In a previous paper [Teor. Verojatnost. i Primenen. **5** (1960), 473–476; MR **24** #889] the author and Zolotunin proposed a general method for approximating multiple integrals by a new Monte Carlo technique. The author now continues the research by considering quadrature formulas of a high degree of precision which use random nodes.

Suppose f belongs to the space of square summable functions in a domain D of k-dimensional Euclidean space, and let φ_m $(m=0,1,\cdots,N)$ be a system of orthonormal functions in D. For approximating the integral $\alpha_j=\int_D \varphi_j(Q)f(Q)dQ$ one uses the sum $K_{n,j}(f)=\sum_{i=0}^{n} A_i(Q_0,Q_1,\cdots,Q_n)f(Q_i)$, where $Q_i\in D$. Let the quadrature formula $\alpha_j=K_{n,j}(f)$ be exact for the functions $\varphi_m(Q)$ $(m=0,1,\cdots,N)$ when the nodes Q_i are random points in D with a given probability denstiy, and let the mathematical expectation of $K_{n,j}(f)$ be α_j. Using the Fourier expansion formula for the function $f(Q)$, one finds the variance $D[K_{n,j}(f)]$. The quadrature formulas with smaller variance present a special interest, i.e., those for which $n<N$ and $D[K_{n,j}(\varphi_m)]<1$. The coefficients $A_m(Q_0,Q_1,\cdots,Q_n)$, for $n=N$, can be uniquely determined by comparatively weak restrictions imposed on the dispositions of the points Q_i. In this case Q_i should satisfy the unique condition $\det\|\varphi_j(Q_i)\|_0^n\neq 0$. When $n<N$, the nodes Q_i must, in addition, satisfy the condition

$$\det\|\varphi_m(Q_i)\varphi_0(Q_i)\cdots\varphi_{j-1}(Q_i)\varphi_{j+1}(Q_i)\cdots\varphi_n(Q_i)\|_0^n = 0.$$

The corresponding quadrature formulas are similar to the Gaussian numerical integration formulas.

Several examples are presented in detail.

D. D. Stancu (Cluj)

Hara, I. S. 5383

On a method of constructing the Hermite interpolation formula and on quadrature formulas for solving boundary-value problems and integral equations. (Russian)

Dokl. Akad. Nauk SSSR **141** (1961), 822–825.

Levin, M. 5384

On best quadrature formulae with fixed nodes. (Russian. Estonian and English summaries)

Eesti NSV Tead. Akad. Toimetised Füüs.-Mat. Tehn.-tead. Seer. **13** (1964), 110–114.

Let $W_0^{(1)}L^{(2)}$ be the class of absolutely continuous functions $f=f(x)$ on $[0,1]$ such that $f(0)=0$ and $\|f'(x)\|\le M$ when $f'(x)\in L^{(2)}$. Consider the quadrature formulas

$$(1)\qquad I(f) = \sum_{k=0}^{n-1} p_k f(x_k)+r_n(f),$$

$$(2)\qquad I(f) = \sum_{k=0}^{n-1} p_k f(x_k)+\sum_{j=0}^{r-1} B_j f(y_j)+R_n(f),$$

where $I(f)=\int_0^1 f(x)dx$ and p_k, x_k and y_j are given numbers. Let $r_n=\sup|r_n(f)|$, $R_n=\sup|R_n(f)|$ when $f\in W_0^{(1)}L^{(2)}$.

The author is concerned with the problem of finding the best quadrature formula (2) when f belongs to the class of functions considered, i.e., the problem of determining the coefficients B_j so that R_n is the smallest. In an earlier paper G. Ja. Doronin [Sb. Naučn. Trudy Dnepropetrovsk. Inž.-Inst. No. 1–2 (1955), 210–217] has shown that the best quadrature formula (1) for this class of functions is obtained if $p_k=2/(2n+1)$, $x_k=(2k+2)/(2n+1)$, $r_n=M/(2n+1)\sqrt{3}$.

Let (1) be the best quadrature formula. The author shows that in the class of functions considered, the best quadrature formula (2), for which $r=n$, $y_k=0.5(x_{k-1}+x_k)$ $(k=0,1,\cdots,n-1;\ x_{-1}=0)$, is the following:

$$I(f) = \frac{2}{2n+1}\sum_{k=0}^{n-1} f\left(\frac{2k+2}{2n+1}\right)+\frac{1}{2(2n+1)}\,f\left(\frac{1}{2n+1}\right)+R_n(f),$$

with

$$R_n = \frac{M}{(2n+1)\sqrt{3}}\sqrt{\frac{8n+1}{8n+4}}.$$

A similar problem is considered when (1) is the iterated Simpson formula and when f is absolutely continuous on $[0, 1]$, whereas $\|f'(x)\| \leq M$ when $f'(x) \in L^{(2)}$.

Day, J. T. 5385
A one-step method for the numerical solution of second order linear ordinary differential equations.
Math. Comp. 18 (1964), 664–668.
The author combines the Lobatto four-point quadrature formula with Hermite interpolation to obtain a one-step method of order six (local truncation error $O(h^7)$) for the numerical integration of linear second-order differential equations. In three examples the method is compared with less accurate methods of Runge-Kutta, Numerov, and the reviewer. *Walter Gautschi* (Lafayette, Ind.)

Hao Šou [Šou, Hao] 5386
A Sturm-Liouville difference problem for a fourth-order equation with discontinuous coefficients. (Russian)
Ž. Vyčisl. Mat. i Mat. Fiz. 3 (1963), 1014–1031.
The difference scheme previously studied by the author [same Ž. 3 (1963), 841–860; MR 28 #724] is used to obtain the eigenvalues and eigenfunctions of the problem $(k(x)u'')''-(p(x)u')'+q(x)u=\lambda r(x)u$, $u(0)=u'(0)=u(1)=u'(1)=0$. Estimates are derived for the error in the nth eigenvalue and corresponding eigenfunction. In the case of smooth coefficients the error is $O(h^2)$ (h is the grid size), and in the case of piecewise smooth coefficients the error is $O(h)$, except that in certain cases (an example is given) the error may be $O(h^2)$ also for piecewise smooth coefficients. *R. C. Gilbert* (Fullerton, Calif.)

Holt, James F. 5387
Numerical solution of nonlinear two-point boundary problems by finite difference methods.
Comm. ACM 7 (1964), 366–373.
Author's summary: "Solution of nonlinear two-point boundary-value problems is often an extremely difficult task. Quite apart from questions of reality and uniqueness, there is no established numerical technique for this problem. At present, shooting techniques are the easiest method of attacking these problems. When these fail, the more difficult method of finite differences can often be used to obtain a solution. This paper gives examples and discusses the finite difference method for nonlinear two-point boundary-value problems."

Maistrov'skiĭ, G. D. 5388
On the applicability of the sweep method. (Ukrainian. Russian and English summaries)
Dopovidi Akad. Nauk Ukraïn. RSR 1964, 449–451.
It is shown that the sweep method will be applicable to the computation of the solution of a certain difference analogue to the two-point problem

$$\{-(py')'+qy=f;\ y'-H_0y|_0=a,\ y'-H_1y|_l=b\}$$

for all sufficiently small h if and only if the operator A:

$$[Ay=-(py')'+qy \text{ for } y|_0=0,\ y'+H_1y|_l=0]$$

is definite. *T. I. Seidman* (Seattle, Wash.)

McGill, Robert; Kenneth, Paul 5389
Solution of variational problems by means of a generalized Newton-Raphson operator.
AIAA J. 2 (1964), 1761–1766.
Authors' summary: "This paper presents the development of an indirect method for solving variational problems by means of an algorithm for obtaining the solution to the associated nonlinear two-point boundary-value problem. The method departs from the usual indirect procedure of successively integrating the nonlinear equations and adjusting arbitrary initial conditions until the remaining boundary conditions are satisfied. Instead, an operator is introduced which produces a sequence of sets of functions that satisfy the boundary conditions but, in general, do not satisfy the nonlinear system formed by the state equations and the Euler-Lagrange equations. Under appropriate conditions, this sequence converges uniformly and rapidly (quadratically) to the solution of the nonlinear boundary-value problem. The computational effectiveness of the algorithm is demonstrated by three numerical examples."

Storey, C.; Rosenbrock, H. H. 5390
On the computation of the optimal temperature profile in a tubular reaction vessel.
Computing Methods in Optimization Problems (Proc. Conf., Univ. California, Los Angeles, Calif., 1964), pp. 23–64. *Academic Press, New York*, 1964.
Given the system $\dot{x}=Fx$, $x(t_0)=x_0$, and F is a 3×3 matrix with $F_{ij}=ae^{-(b/u+c)}$, where a, b, c are given constants, find the control program $u(t)$ (temperature profile) such that $x_3(T)$ is maximized. Five numerical methods were studied experimentally in connection with the solution of this problem: (i) discrete approximation and conversion to a straight hill-climbing problem of many variables, (ii) Rayleigh-Ritz method using ramps and exponentials, (iii) direct attempt at solving the two-point boundary-value problem by guessing the missing multipliers, (iv) gradient method, which is not really different from (i), and (v) dynamic programming. It was found that (i) and (iv) worked best. *Y.-C. Ho* (Cambridge, Mass.)

Homogeneous difference schemes. (Russian)
Ž. Vyčisl. Mat. i Mat. Fiz. 1 (1961), 5–63.
The authors summarize results obtained in their work between 1956 and 1960 [Dokl. Akad. Nauk SSSR 122 (1958), 562–565; MR 23 #B1656a; ibid. 122 (1958), 188–191; MR 20 #6651; ibid. 108 (1956), 393–396; MR 18, 938; ibid. 124 (1959), 529–532; MR 23 #B1656b; Uspehi Mat. Nauk 14 (1959), no. 3 (87), 185–188; Dokl. Akad. Nauk 124 (1959), 779–782; MR 25 #4642; ibid. 131 (1960), 514–517; MR 27 #6392; ibid. 131 (1960), 761–764; MR 27 #6393; ibid. 131 (1960), 1264–1267; MR 27 #6394], where they studied homogeneous schemes for the solution of the first boundary-value problem

$$\text{(1)}\qquad L^{(k,q,f)}u=[k(x)u']'-q(x)u+f(x)=0,$$

$$0<x<1,\ u(0)=\bar{u}_1,\ u(1)=\bar{u}_2,$$

whose coefficients k, q, f are piecewise continuous functions with $k(x)\geq M>0$, $q(x)\geq 0$. In § 1 they characterize the family of difference schemes for the differential equation (1) in the class $Q^{(0)}$ of piecewise continuous coefficients. In

§ 2 they study problems connected with the convergence and accuracy of homogeneous difference schemes in the class of smooth coefficients $C^{(m)}$. In § 3 they study the convergence of a certain solution of the difference equation to the solution of equation (1), and give a certain necessary condition for this convergence. In § 4 they introduce a perturbation norm for the coefficients of a scheme and define what they refer to as the co-stability of a difference scheme. They show that a necessary and sufficient condition for the co-stability of a canonical scheme is that it be conservative. In § 5 the authors discuss questions relating to convergence and accuracy of conservative difference schemes.

Homogeneous difference schemes on irregular meshes. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **2** (1962), 812–832.

The authors continue their work [#5391] on homogeneous difference schemes for the equation $(k(x)u')'-q(x)u+f(x)=0$, $0<x<1$. In the present paper an irregular mesh $x_0=0, \cdots, x_i, \cdots, x_N=1$ is considered. A typical result is the following. Let $[a_{i+1}(y_{i+1}-y_i)-a_i(y_i-y_{i-1})]-d_iy_i+g_i=0$ for $i=1, \cdots, N-1$, where $a_i=[\int_{x_{i-1}}^{x_i}\{dt/k(t)\}]^{-1}$, $d_i=\int_{(x_{i-1}+x_i)/2}^{(x_i+x_{i+1})/2}q(t)\,dt$ and $g_i=\int_{(x_{i-1}+x_i)/2}^{(x_i+x_{i+1})/2}f(t)\,dt$. If $u(x_0)=y_0$, $u(x_N)=y_N$, $k(x)>0$, $q(x)\geq 0$ and the first derivatives of k, q, f satisfy Lipschitz conditions in $[0, 1]$, then $\max_i|y_i-u(x_i)|\leq M\sum_{i=1}^N(x_i-x_{i-1})^3$, M being independent of the mesh points. *H. J. Norton* (Teddington)

Vasil'ev, F. P. 5393

A difference method of solving problems of Stefan type for a quasi-linear parabolic equation with discontinuous coefficients. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1280–1283.

The author solves a rather complicated two-phase nonlinear free boundary diffusion problem by utilizing an implicit-difference scheme. He asserts that the resulting nonlinear algebraic equation can be solved iteratively and that the solutions converge to the solution of the original problem as the mesh size vanishes. No proofs are given in the paper. *W. T. Kyner* (Los Angeles, Calif.)

Volčenko, A. P.; Poddubnyĭ, E. P. 5394

A method of solving differential equations on an electronic computer. (Russian. English summary)

Bjull. Inst. Teoret. Astronom. **9** (1963/64), 587–600.

Authors' summary: "A quadratic method of numerical integration of differential equations is proposed, founded on Bessel's interpolation formula. The working formulas giving the possibility of solving the equations with the automatic choice of integration pitch by means of the electronic computer are obtained."

Birkhoff, Garrett; Varga, Richard S.; Young, David 5395

Alternating direction implicit methods.

Advances in Computers, Vol. 3, pp. 189–273. Academic Press, New York, 1962.

The authors survey the theory of the original two alternating direction iteration (ADI) methods due to Peaceman, Rachford and the reviewer, and some variants due to Wachspress, Habetler, and the authors. The first part treats the case of a single iteration parameter. The relations between the various methods are pointed out, and a reasonably complete convergence analysis is clearly presented. A method for the selection of the optimum or a nearly optimum parameter is derived. The second part of the paper is concerned with the case in which all operators involved commute. Again, a satisfactory analysis exists and is exhibited in an elegant fashion. The third part considers the relation between ADI methods and successive overrelaxation (SOR). Primarily, a nice summary of SOR methods is given, along with a few results involving ADI methods. It is pointed out that the ADI method of Peaceman and Rachford is an SOR method for a larger matrix. The fourth part presents the results of two series of numerical experiments with ADI and SOR methods on Dirichlet problems. In general, the ADI results compare favorably with the SOR results for sufficiently small mesh size. The appendices are concerned with specialized questions concerning the choice of optimum parameters and commutativity. Transient problems are not considered, nor are any of the iterative variants that have been invented in the last few years.

Çakiroğlu, Adnan; Kayan, İlhan 5396

Exact forms of finite difference equations for certain differential equations. (Turkish summary)

İstanbul Tek. Üniv. Bül. **16** (1963), 77–99.

The authors give exact finite-difference forms of the following differential equations: $W''=f(x)$, $W^{(\mathrm{iv})}=f(x)$, $\Delta W=f(x, y)$, $\Delta\Delta W=f(x, y)$. The left-hand sides of these exact equations are the first-order finite-difference relations given in the classical form, and the right-hand sides are integral expressions such as $\int f(x)\cdot K(x)\,dx$ or $\iint f(x, y)\cdot K(x, y)\,dx\,dy$. The authors determine the K functions by constructing elastic models and applying Betti's reciprocal theorem to the equivalent elastic problems. For the equation $W''=f(x)$ they obtain, in particular, the "funicular polygon formula" of F. Stussi [Z. Angew. Math. Phys. **1** (1950), 53–70; MR **11**, 405]. The results obtained with this method would be more accurate than those found by the classical finite-difference method. The authors consider also some boundary conditions which occur in elasticity theory. *A. Dou* (Madrid)

Greenspan, Donald 5397

Approximate solution of axially symmetric problems.

Comm. ACM **7** (1964), 373–377.

Author's summary: "A variety of physical problems in such diverse fields as electrostatic field theory, heat and ideal fluid flow, and stress concentration theory reduce, under the assumption of axial symmetry, to the study of the elliptic partial differential equation $\partial^2u/\partial x^2+\partial^2u/\partial y^2+k/y(\partial u/\partial y)=0$. Dirichlet-type problems associated with this equation are studied on regions whose boundaries include a nondegenerate portion of the x-axis, and exceedingly accurate numerical methods are given for approximating solutions."

Ljašenko, I. M. 5398

Remarks on the method of matrix sweeping. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 458–461.

From the author's summary: "Application of the matrix double-sweep method to boundary-value problems for $\Delta v - 2\lambda v = f$ in a rectangle involves cumbersome calculations due to the necessity of inverting nth-order matrices at each step. By a transformation involving certain special matrices it is possible to reduce the procedure to computations for which the only required matrix inversions are of diagonal matrices."

Položiĭ, G. N. [Положий, Г. Н.] 5399

★**Numerical solution of two- and three-dimensional boundary-value problems of mathematical physics and functions of a discrete argument [Численное решение двумерных и трехмерных краевых задач математической физики и функции дискретного аргумента].**

Izdat. Kiev. Univ., Kiev, 1962. 161 *pp*. 0.55 *r*.

In two dimensions some finite-difference approximations to linear partial differential equations may be written in the form

$$(1)\quad \sum_{p=0}^{m} a_{pk}[u_k(x-ph)+u_k(x+ph)] + \sum_{p=1}^{m} b_{pk}[u_{k+p}(x)+u_{k-p}(x)] = f_k(x),$$

where m is a small integer (often $m=2$) and $u_k(x) = u(x, y_0+kh)$, $k=0, \cdots, n+1$. By using the transformation of the $n\times n$ matrix $B\,(=b_{pk})$ into diagonal form ($B=PDP$), the author reduces equations (1) to the equations

$$(2)\quad \sum_{p=0}^{m} a_{pk}[\hat{u}_k(x-ph)+\hat{u}_k(x+ph)] = \phi_k(x).$$

The solution $\hat{u}_k(x)$ of (2) may then be written in explicit form.

In the first chapter the solution of equations (2) is discussed and also the reduction of B to diagonal form. The second chapter deals with the derivation and transformation of approximations (1) for Laplace's, Poisson's, and the biharmonic equations, and also equations of parabolic and hyperbolic type with constant coefficients. The extension of the method to curvilinear boundaries and three-dimensional problems is described. Brief consideration is given of equations with variable coefficients.

This method would appear to be useful in avoiding round-off errors when a small mesh, and consequently a large number of nodes, is required.

On non-rectangular interlacings. (Russian)

Trudy Moskov. Mat. Obšč. **9** (1960), 537–561.

Introducing the notion of an interlacing by a topological mapping, and using the notion of three families of curves called the generators of the interlacing, the authors generalize their earlier work [Mat. Sb. (N.S.) **48** (**90**) (1959), 377–395; MR **22** #4125; Dokl. Akad. Nauk SSSR **131** (1960), 249–252; MR **23** #B2609] on the nomographability of a function $z=f(x, y)$ in certain non-rectangular regions.

A. J. Lohwater (Providence, R.I.)

Bowman, Howard S. 5402

A nomogram for computing $\dfrac{a+jb}{c+jd}$ and a nomogram for computing $\left|\dfrac{a+jb}{c+jd}\right|$.

Nat. Bur. Standards Tech. Note No. 250 (1964), ii + 13 *pp*.

Author's summary: "This report gives two nomograms designed and constructed for use in computing complex ratios of two-dimensional vector quantities. One nomogram can be used to compute the real and imaginary parts of a vector ratio, and the other to compute the absolute value of such a function. Whenever a large number of vector ratios are required in data reduction, the use of these nomograms saves time in manual processing."

Galajda, P. 5403

A nomogram for functions of the first nomographic class in the complex domain. (Slovak. Russian and German summaries)

Acta Fac. Natur. Univ. Comenian. **9**, 83–93 (1964).

Smirnov, S. V. 5404

Uniqueness of a nomogram of aligned points with one rectilinear scale. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 910–922.

An alignment nomogram is called degenerate if all three scales lie on one plane curve of third order. All nomograms projective among themselves form a projective class. Vaona proved that in the general case the number N of projective classes of nomograms is $N \le 11$.

Here the author considers nomograms with one rectilinear scale, and proves that, in the class of nomograms of this type, $N \le 1$.

It can be shown from this particular result that the complete solution of the problem of uniqueness in the general case may be obtained. This particular case forms the content of the present paper. The paper makes use of the so-called nomographic invariants introduced by Blaschke.

★Un nouveau langage scientifique: ALGOL. Manuel pratique.

Actualités Sci. Indust., No. 1310. *Hermann, Paris*, 1964. 196 *pp.* (2 *inserts*) 36.00 *F.*

This is a fine description of the ALGOL 60 language, containing an impressive amount of material. The authors have made very effective use of flow diagrams to illustrate the syntactical forms in the language, and there are many examples of the various constructions. It is a manual for the language, not a primer, so it would probably not be easy for someone to learn this on his own, but with some help available, this should be a very useful book. The authors also went far beyond a mere description of the language. Once the language is explained, there are concise but effective discussions of translation techniques and character representations on several computers, as well as the complete revised report on the ALGOL 60 language, an index to all ALGOL algorithms published in Comm. ACM, and a very complete bibliography of articles (and even published letters) relating to ALGOL. As a bonus, inside the back cover is a large syntactic chart of the entire language. The only disconcerting feature is the transliteration of English key words in ALGOL into French, such as "pour" instead of "for", but then, why not!

Foxley, Eric 5408

Determination of the set of all four-variable formulae corresponding to universal decision elements using a logical computer.

Z. Math. Logik Grundlagen Math. **10** (1964), 302–314.

In order to determine all four-variable formulae corresponding to universal decision elements [cf. A. Rose, same Z. 4 (1958), 169–174; MR **21** #1924] a method is developed which is suitable for use on the Nottingham University logical computer. Mechanisms necessary for subtests are also discussed in detail. The total number of operations to be performed turns out to be approximately one million and the number of decision elements required less than 90. The result is that there are 263 essentially different (i.e., not obtainable from each other by mere permutation of variables) four-variable formulae for universal decision elements. *V. Devidé* (Zagreb)

Garwick, Jan V. 5409

Data storage in compilers.

Nordisk Tidskr. Informations-Behandling **4** (1964), 137–140.

Author's summary: "Arrays in ALGOL 60 are dynamic in the sense that an array with the same name may be declared several times but with different dimensions. In a compiler this is usually of no interest because the arrays are declared only once but the programme does not in advance know how big they should be. A storage system which dynamically changes the size of arrays is described. The extra time required to perform these changes of array size so the available store is used in an optimal way is very small, and the gains in efficiency of the programme can be considerable."

Gelernter, Herbert 5410

Machine-generated problem-solving graphs.

Proc. Sympos. Math. Theory of Automata (New York, 1962), *pp.* 179–203. *Polytechnic Press of Polytechnic Inst. of Brooklyn, Brooklyn, N.Y.*, 1963.

Author's introduction: "Problems for which no well-defined solution procedures exist generally present the problem solver, at several stages during his search for a solution, with the necessity for choosing one path (hopefully, the best one) from among many alternative possibilities that present themselves at a given point. The process of solution may be formally represented by a tree-like structure called the problem-solving graph. When the problem-solving agent is a machine, rather than human, the generation, manipulation, and traversal of the problem-solving graph must be specified with precision and care. A properly constructed graph will not only favor the discovery of more elegant and efficient problem solutions, but will also guard the machine against certain pitfalls that humans seem to avoid naturally."

A. P. Ershov (Novosibirsk)

Ginsburg, Seymour 5411

Abstract machines: A generalization of sequential machines.

Proc. Sympos. Math. Theory of Automata (New York, 1962), *pp.* 125–138. *Polytechnic Press of Polytechnic Inst. of Brooklyn, Brooklyn, N.Y.*, 1963.

A complete sequential machine is a 5-tuple $S = (K, \Sigma, \Delta,$

δ, λ), where (i) K is a finite set of "states"; (ii) Σ is a finite set of "inputs"; (iii) Δ is a finite set of "outputs"; (iv) δ is a "transition" function which maps $K \times \Sigma$ into K; (v) λ is an "output" function which maps $K \times \Sigma$ into Δ.

A quasi-machine is a 5-tuple $(K, W, Y, \delta, \lambda)$, where (1) K is a set of "states"; (2) W and Y are semigroups of "inputs" and "outputs", respectively; (3) δ is a mapping of $K \times W$ into K such that $\delta(q, IJ) = \delta(\delta(q, I), J)$ for each $q \in K$ and all I and J in W; (4) λ is a mapping of $K \times W$ into Y such that $\lambda(q, IJ) = \lambda(q, I)\lambda(\delta(q, I), J)$ for each $q \in K$ and all I and J in W.

An abstract machine is a quasi-machine in which the output semigroup satisfies the left cancellation law.

Main results: (I) abstract machines model many certain situations in data processing computers; (II) redundant (=equivalent) states may always be removed from an abstract machine, but not always from a quasi-machine; (III) equivalent inputs of an abstract machine can be removed; (IV) a synthesis procedure that is always successful is given for synthesis of an abstract machine with no equivalent inputs, which has a specified input structure.

A. P. Ershov (Novosibirsk)

Gram, Christian 5412

On the representation of zero in floating-point arithmetic.

Nordisk Tidskr. Informations-Behandling **4** (1964), 156–161.

Author's summary: "Two representations of zero in floating-point arithmetic are considered in relation to a summation with correction for rounding errors. The common representation with exponent zero is shown in this case to be better than the 'academic' representation where the exponent depends on the 'history' of the zero."

Lombardi, Lionello A. 5413

Mathematical models of file processes.

Atti Sem. Mat. Fis. Univ. Modena **12** (1962/63), 173–214.

The author develops what he calls a non-procedural language primarily designed for non-arithmetic processes, independently of the procedures they involve (Algebraic Data System Language). This language is based on what the author calls a theory of files. A file is a set of items of information which is logically orderable, and which is ordered by a mapping into the linearly ordered set of natural numbers or an isomorphic ordered set. Apart from computational elements similar to the basic part of ALGOL, table operations and so-called flow control expressions involving files are proposed.

The presentation is partly sketchy, partly vague; it does not discuss implementation nor is it precise enough to define implementation implicitly. How tentative the formulations are is illustrated by the sentence (p. 205): "this requires a careful analysis of the procedure description in order to detect tautologies and to determine the independence among expressions; this analysis has to be done by the system at compilation time", and a reference made at this point to the books of Church, Phister, Roth, Quine and Barankin, which indicates quite an enormous task.

F. L. Bauer (Munich)

Svoboda, A.; Čulík, K. [Čulík, K.] 5414

An algorithm for solving Boolean equations. (Russian. English summary)

Automat. i Telemeh. **25** (1964), 374–381.

The authors present a straightforward procedure for determining the set of solutions of a system of Boolean equations

$$F_i(x_1, \cdots, y_1, \cdots) = G_i(x_1, \cdots, y_1, \cdots), \qquad i = 1, \cdots, n,$$

where the x_j are independent variables and the y_k are the unknowns. A simple encoding of the algorithm requires about 2^L bits of memory for storing the graphs of functions defined by the F_i and G_i; here $L = 2m + r$, where m is the number of y_k and r is the number of x_j. The paper ends with a proof of a theorem stating a characterizing condition under which the solutions of the above system of equations exist and (when they do) the number of such solutions.

R. M. Baer (Berkeley, Calif.)

Trotter, H. F. 5415

A machine program for coset enumeration.

Canad. Math. Bull. **7** (1964), 357–368.

The author gives an algorithm and a few hints of an IBM 7094 program for determining the index of a subgroup of cosets H of a group K. Here K is specified by a finite set of generators and relations between them and H is specified as generated by a given finite set of words in the generators of K. The method is "much the same" as that of Leech [Proc. Cambridge Philos. Soc. **59** (1963), 257–267; MR **26** #4513]. In practice this problem tends to run out of storage space. The present program has features to alleviate this distress. The number of generators is limited to nine. As a test, the program found the 448 cosets of $\{A^2, A^{-1}B\}$ in the group generated by A and B, with the relations $A^8 = B^7 = A^2B^2 = A^{-3}B^3 = 1$, in six seconds.

★**Hamiltonian dynamics.**

Mathematical Physics Series, 2.

John Wiley and Sons, Inc., New York, 1964. ix+146 *pp.* $4.75.

This booklet is an introduction to analytical mechanics intended, it appears, mainly for mathematicians. Most of the material can be found in other textbooks, but the emphasis and approach are often different from the more usual ones. After a brief introductory chapter reminding the reader of the Newtonian equations of motion, rigid body dynamics, constraints, tensor calculus, and so on, the author discusses in the other chapters the Lagrangian equations, both with the time as a parameter and with the time as an extra coordinate, and the Hamiltonian equations.

In the chapters on Lagrangian theory, Feynman's path integral method is discussed in some detail, a topic not usually found in a text on classical mechanics. On the other hand, in the chapters on Hamiltonian theory one misses a discussion of action and angle variables, of such great importance both in celestial mechanics and in modern plasma physics, and a discussion of classical perturbation theory which is such a delightfully elegant discipline. However, the author may have opted intentionally for a short, sweet account rather than a more comprehensive one. There are various historical notes, of which the longest and most delightful one is the story of Maupertuis' principle. *D. ter Haar* (Oxford)

Ferrarese, Giorgio 5420

Sulle equazioni di moto di un sistema soggetto a un vincolo anolonomo mobile.

Rend. Mat. e Appl. (5) **22** (1963), 351–370.

The author first considers a holonomic Lagrangian system of n degrees of freedom, subject to variable frictionless constraints. The equations of motion, with a separately postulated energy equation, are written as path equations in a Riemannian $(n+1)$-space. Next, the author considers the addition of a variable anholonomic constraint, linear in the velocities. This is interpreted geometrically, and it is shown how, by the introduction of $(n+1)$ reference congruences, the force due to the new constraint may be made to disappear from the path equations. There remain n equations for n unknowns, which are then restored to Lagrangian form. There appear, added to the generalized forces, new terms which vanish when (1) the constraint is in fact holonomic, or (2) the coordinates are suitably chosen. A large part of the article is devoted to the theory of congruences and to the explanation of the Ricci rotation coefficients. *R. H. Boyer* (Austin, Tex.)

Károlyházy, F. 5421

Mach's principle and general relativity. (Russian summary)

Acta Phys. Acad. Sci. Hungar. **17** (1964), 31–40.

The author gives a clear and eloquent exposition (almost without equations) of the implications of Mach's principle of the relativity of inertia for Newtonian mechanics, special relativity, and general relativity. He concludes with the interesting suggestion that the solutions of Einstein's field equations should be restricted by the following criterion, which he asserts could easily be made rigorous: "A physical solution S, that is a complete regular space-time with an everywhere acceptable (non-negative) mass density, etc., obeying equations $R_{ik}-\frac{1}{2}g_{ik}R=-\kappa T_{ik}$ is permissible if it is impossible to give a set $S(p)$ of other physical solutions, depending continuously on the parameter p, and a set $\Sigma(p)$ of space-time domains, where $\Sigma(p)$ is a suitably chosen domain of $S(p)$, in such a manner that $S(p_0)=\Sigma(p_0)=S$ and, for some other value p_1 of p, $\lim_{p\to p_1}\Sigma(p)=S_p$, where S_p describes a completely empty but otherwise complete and regular space-time." *F. Motor operators in curvilinear coordinates. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 322–327.

Author's summary: "The author discusses operations on biscalar functions and motor functions in curvilinear coordinates, and the formulae of Jacobi and Lamé are extended to motor and biscalar fields."

Osipov, P. M. 5423

Bi-scalar and motor fields. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 740–744.

Author's summary: "The concept of directional derivative is extended to biscalar and motor fields. An expansion of biscalar and motor fields into Taylor's series by means of directional derivatives of higher orders of three fields is given. Diad identities are obtained, expressed in terms of directional derivatives of motor fields. These identities are applied to the integration of motor equations."

On the kinematics of multi-dimensional Euclidean spaces. (Russian summary)

C. R. Acad. Bulgare Sci. **16** (1963), 573–576.

A kinematic matrix-operator is defined for n-dimensional Euclidean spaces, and is used to generalize the basic velocity and acceleration formulas. Known properties of

acceleration of any order in two- and three-space are explained in this general context.

For motion with one point fixed, the maximum and minimum dimensions of the linear varieties which correspond to the loci of zero velocity are determined according to whether n is even or odd.

Questioni di dinamica del corpo rigido.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 35–39.

The author considers a rigid body rotating about a fixed point O, under the general hypothesis that the moment of the applied forces with respect to O is a function of the angular velocity ω and of a constant vector H. Various important physical problems are included as special cases. Conditions are given under which the equations of motion possess two integrals which are linear and quadratic, respectively, in the components of ω. The problem of the explicit determination of the motion is discussed briefly.

Silven, Saul 5431

Application of operational methods to the analysis of the motion of rigid bodies.

J. Mathematical Phys. **5** (1964), 1424–1426.

This paper deals with an application of an extension of one-sided Laplace transforms to vector functions $\mathbf{f}(t)$. The transform of such a function is defined by the new vector function

$$\mathbf{F}(\mathbf{S}) = \int_0^\infty \exp(-\mathbf{S}t)\mathbf{f}(t)\,dt,$$

the tensor $\mathbf{S}$ of which corresponds to the scalar operational variable p or s of the conventional operational calculus. The rules based on this definition are completely analogous to those holding for scalar Laplace transforms. They are applied here to solve the equation of motion (in a linearized approximation) for the angular-velocity vector of a rigid body, the coordinate system being attached to this body. The transformed equation is solved first, with the aid of matrix analysis. The derived results refer to a few special cases for the torque generating the motion of the rigid body; the solutions can be interpreted in terms of precessional motions of the angular-velocity vector.

Remarks on variational principles in elastodynamics.
J. Franklin Inst. **278** (1964), 1–7.
The author presents a derivation of the complementary extremum principle for general small vibrations of an elastic body. For the steady vibration case this was given earlier by Reissner [J. Math. and Phys. **27** (1950), 90–95; MR **12**, 301]. *J. Miklowitz* (Pasadena, Calif.)

Kupradze, V. D.; Aleksidze, M. A. 5435
The method of functional equations for the approximate solution of certain boundary-value problems. (Russian)
Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 683–715.
The same authors [Soobšč. Akad. Nauk Gruzin. SSR **30** (1963), 529–536; MR **27** #5039] have earlier discussed methods of approximation to the formal solutions of boundary-value problems of elliptic partial differential equations when these solutions are expressed as functionals. In the present paper, these methods are discussed further and are now applied to fundamental problems in harmonic function theory and elasticity theory, some simple illustrative numerical examples being given. It is stated that the new methods compare favourably in application with the more usual methods of the calculus of variations and of finite differences, and also there are applications to problems whose solution leads to singular integral equations. *H. G. Hopkins* (Sevenoaks)

A property of the solution of the third and fourth boundary-value problems of the statics of anisotropic elastic bodies. (Russian. Georgian summary)
Soobšč. Akad. Nauk Gruzin. SSR **34** (1964), 283–290.
This paper concerns the solution of the third and fourth boundary-value problems of elasto-statics for bodies of anisotropic material under two-dimensional conditions. These problems refer to situations in which either (i) the normal displacement and the tangential stress, or (ii) the tangential displacement and the normal stress, respectively, are prescribed at the boundary of a region, certain analytical conditions being imposed. The analysis leading to the formal solution of the problems for anisotropic material is an extension of earlier, closely related analysis applying for isotropic material, and it is based similarly upon applications of potential theory and singular integral equations. Restriction is made to finite and simply-connected regions, but it is stated that this may be relaxed without difficulty so that the analysis includes cases of infinite and multiply-connected regions. Furthermore, it is stated that similar analysis can be developed for the theory of bending of anisotropic plates.

Davies, G. A. O.; Buchwald, V. T. 5438
Plane elastostatic boundary value problems of doubly connected regions. II. The orthotropic ring.
Quart. J. Mech. Appl. Math. **17** (1964), 271–277.
The technique developed by the authors for obtaining solutions of the two-dimensional biharmonic equation for a doubly connected region consists of using combinations of the complex potentials to satisfy exactly the conditions on one boundary. On the other boundary the potential is supposed expanded as a Laurent series, the coefficients being determined exactly or approximately by the boundary conditions. This procedure can be extended to other fourth-order partial differential equations, in particular, to elastic problems with general anisotropy. Here the extension is, for simplicity, confined to orthotropy. The illustrative problem is that of an annulus under internal pressure, approximate calculations being made by the method of collocation with 22 coefficients. Graphs and a brief discussion are given.

Spencer, A. J. M. 5439
Perturbation methods in plasticity. II. Plane strain of slightly irregular bodies.
J. Mech. Phys. Solids **10** (1962), 17–26.
Part I appeared in same J. **9** (1961), 279–288 [MR **24** #B1815]. Author's summary: "A perturbation method is formulated for the problem of plane plastic strain of a body B which differs slightly in shape from a second body B_0, when the solution for B_0 is known and similar boundary conditions obtain for the two bodies; the case in which B undergoes continuous deformation but can at all times be regarded as a perturbation of B_0 is also considered. Examples solved are the indentation of an almost plane surface, and the continued indentation of an initially plane surface by the curved surface of a parabolic cylinder. This last problem closely approximates the two-dimensional analogue of the Brinell hardness test."

Zahnfussfestigkeit geradverzahnter Stirnräder.

Mem. Fac. Engrg. Hiroshima Univ. **2**, *no.* 2, 15–55 (1964).

Authors' summary: "Wir haben die theoretische Untersuchung über die Größe der auf dem gefährlichen Querschnitt entstandenen Spannung angestellt und geklärt, daß die Spannung auf der Filetkurve immer größer als diejenige innerhalb des Zahns ist. Daraus hat es sich ergeben, daß die Zahnfußfestigkeit durch Anwendung der Berechnungsgleichung der maximalen Spannung entlang der an der Zugseite befindlichen Filetkurve berechnet werden kann. Aufgrund dieses Ergebnisses haben wir die maximalen Spannungen der verschiedenen Zahnprofile entlang der Filetkurve berechnet, und einen Vorschlag gemacht, daß der gefährliche Querschnitt durch die Hofersche Methode mit genügender Genauigkeit gesucht wird. Im Vergleich der maximalen Spannung, wenn die konzentrische Biegungsbelastung auf den Zahn wirkt, mit derjenigen, wenn das reine Biegungsmoment wirkt, ist es nachgeprüft worden, daß man die Schubspannung berücksichtigen muß, wenn man die Berechnungsgleichung der Fußfestigkeit erhalten will. Ferner haben wir gefunden, daß der Formfaktor bei Einwirkung der Druckkomponente von der Belastung auf den Zahn zu demjenigen bei Einwirkung des reinen Biegungsmoment im Verhältnis steht. Als Ergebnis dieser Untersuchungen haben wir folgende Berechnungsgleichung der maximalen Spannung geführt:

$$\sigma_t = \left(1+0.08\frac{S}{\rho}\right)(0.66\sigma_{Nb}+0.40\sqrt{(\sigma_{Nb}^2+36\tau_N^2)}+1.15\sigma_{Nc}).$$

Mit Anwendung der obigen Gleichung kann man die Biegungsspannung all der Evolventenstirnräder mit geraden Zähnen und der Zahnräder mit den ähnlichen Profilen berechnen." *R. M. Morris* (Cardiff)

On the axially symmetric deformation of a nonhomogeneous, elastic material.

J. Franklin Inst. **278** (1964), 327–336.

Authors' summary: "The problem of stress analysis of a solid of revolution, deformed symmetrically with respect to the axis, in which the elastic 'constants' are arbitrary functions of the radial and axial coordinates, is considered. The solution of the torsion-free problem is formulated in terms of two stress functions which are determined by two coupled partial differential equations with variable coefficients. The torsion problem is solved by means of a single stress function. In addition, the following three special cases of interest to engineers are considered: (1) Torsion of a circular bar of varying section, (2) Circular bar in tension, (3) Pressurized thick cylinder."

Sucher, M. 5443

On a certain generalization of the Michell problem. (Polish and Russian summaries)

Arch. Mech. Stos. **15** (1963), 645–657.

The generalised Michell problem consists in the determination of the stress in two different elastic half-planes of uniform thickness united along a common straight edge, and acted upon by a concentrated force applied to one of the planes. The solution is found here, when both planes are anisotropic, by the use of Fourier integrals, but the end results are expressed in closed form in terms of elementary functions. Various particular cases are discussed, including the solution by Mossakovski for the anisotropic half-plane with its edges free from stress. The case where the planes are isotropic is obtained by a limiting process. *L. M. Milne-Thomson* (Tucson, Ariz.)

Zur Lösung eines Minimum-Problems der nichtlinearen Plattentheorie.

Math. Nachr. **26** (1963/64), 339–351.

Es wird das Minimum-Problem für Platten untersucht, die sowohl physikalisch als auch geometrisch nichtlinear deformiert sind. Die Formulierung der Variationsgleichungen wird einer Monographie von W. W. Nowoshilow entnommen. Die Funktion des Verschiebungsvektors, deren Minimaleigenschaften untersucht werden, wird aus dem Prinzip der virtuellen Verschiebungen gewonnen. Für diese Funktion wird eine Reihe von charakeristischen Sätzen abgeleitet. *F. Chmelka* (Vienna)

Szmodits, K. 5449

Solution numérique simplifiée des problèmes de plaques. (English, German, and Russian summaries)

Acta Tech. Acad. Sci. Hungar. **48** (1964), 231–239.

Author's summary: "The paper deals with the numerical solution of the bipotential plate equation. The described method unifies the difference and Ritz's method, and determines the elastic surface $w(x, y)$ sought for having the same value-set as that which results on the base of the difference method. The advantage of the method dealt with in comparison to the difference method is, that for a simply supported plate, the value-set w sought for can be produced without the solution of difference equations and without a considerable loss in numerals. For fully clamped plates, difference equations comprising great transversal terms and being by iteration quickly solvable, can easily be set up."

De Silva, C. N. 5450

The effect of transverse shear deformation on the bending of elliptic toroidal shells.

J. Soc. Indust. Appl. Math. **12** (1964), 465–476.

The second-order complex differential equation derived for the title problem by Naghdi [Quart. Appl. Math. **15** (1957), 41–52; MR **20** #4959] is solved by asymptotic integration. The approximate solution, valid for large values of a shell geometry parameter μ, is given in terms of Hankel functions of orders 1/3 and $-2/3$, and reduces upon specialization to the solution for circular toroidal shells given by Clark [J. Mathematical Phys. **29** (1950), 146–178; MR **12**, 567] for the case of classical shell theory. *H. J. Weinitschke* (Hamburg)

Masur, E. F. 5451

On the consistency of linear structural shell theory.

J. Mécanique **3** (1964), 3–14.

The author discusses the equations of linear shell theory with emphasis on the strain-displacement relations. The techniques of introducing "modified" or "generalised" stress and strain measures, as has been done in some of the recent literature, leads to certain new difficulties when the theory is extended to include transverse shear strains. The author offers a solution to some of these questions and leaves others open. *J. L. Sanders, Jr.* (Cambridge, Mass.)

Payton, R. G. 5452

Bond stress in cylindrical shells subjected to an end velocity step.

J. Math. and Phys. **43** (1964), 169–190.

Concluding remarks: "We have considered the dynamic bond stress in a semi-infinite cylindrical shell composite resulting from a velocity step end impact. For the particular shell considered, e.g., an epoxy-plastic metal combination, it was found that the peak stress occurred during the early stage of the shell motion. If we had applied a velocity pulse, rather than a velocity step, to the end of the structure, the same bond-stress pattern would have developed along the bond for a distance, measured back from the leading front, equal to the pulse width. Also if the structure were finite in length instead of semi-infinite, the stress pattern would remain the same until reflections from the other end occurred. No attempt has been made to analyze the changes in the stress pattern caused by varying the parameters α and c. This, together with the applied-pressure boundary condition, we hope to consider in the future." *B. A. Boley* (New York)

Vol'mir, A. S.; Kil'dibekov, I. G. 5453

Non-linear acoustical vibrations of a cylindrical shell. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **17** (1964), *no.* 3, 65–70.

The forced vibrations of cylindrical panels supported in an acoustic field are considered. From the flexure equation, the equation of compatibility of the deformations (both nonlinear) and the equation for the initial bending $f(t)$, a second-order ordinary differential equation is derived by the Galerkin method for the parameter $\zeta = f(t)/h$. This furnishes a first approximation to the bending in terms of the independent variable $\tau = \omega t$, where ω is the forcing frequency. In the static case this equation leads to a cubic polynomial in ζ, the zeros of which give the values of ζ for which the shell is in equilibrium. Graphs of this function are plotted for square panels having various degrees of curvature. The effect of an initial irregularity in the form of the middle surface is shown. Amplitude-frequency characteristics are drawn for these cases and also for the case in which the panel is subjected to an additional longitudinal stress. *R. N. Goss* (San Diego, Calif.)

Woźniak, Cz. 5454

Finite deformation of shells (analysis of the strain geometry). (Polish and Russian summaries)

Arch. Mech. Stos. **15** (1963), 535–545.

The author suggests adoption of the affinors of the mapping of the undeformed shell space on the deformed shell space as measures of finite strain. These have, according to the author, certain advantages over the Cauchy-Green measures from the point of view of group

theory. The author does not discuss possible disadvantages from the point of view of applied mechanics.

J. L. Sanders, Jr. (Cambridge, Mass.)

Perkins, R. W.; Evan-Iwanowski, R. M. 5455

Mechanical dislocations and physical processes of anisotropic bodies.

J. Franklin Inst. **278** (1964), 337–351.

Authors' summary: "The necessary and sufficient conditions which must be satisfied by a physical process (e.g., the diffusion of heat through a body) in order that its mechanical effects can be represented by mechanical dislocations are derived for anisotropic media. It has been found that the only kind of physical processes which can be represented by mechanical dislocations are those which are steady-state processes with respect to time. Further, it has been found that in order for a steady-state physical process to be represented by mechanical dislocations in an anisotropic body, certain relationships between the coefficients which govern the physical process must be satisfied. Several examples of materials and processes for which the required relationships are satisfied have been presented."

Menditto, Giovanni 5456

Sull'instabilità dinamica flesso-torsionale delle travi alte.

Ist. Lombardo Accad. Sci. Lett. Rend. A **97** (1963), 796–816.

In the present paper the author discusses the bending and torsional dynamical instability of deep beams. These are thought to be stressed transversely and axially by pulsating loads which are either distributed or concentrated.

In particular, the cases are considered of beams with rectangular section and of double-T section, which are stressed either by a pulsating transverse load of arbitrary continuous distribution or by two pulsating eccentric axially concentrated loads. In each case the instability problem is reduced to the existence of unbounded solutions of linear periodic differential systems $x' = (A + \lambda B(t))x$, where A is a constant diagonal matrix, λ a small parameter, $B(t)$ a given $n \times n$ periodic matrix of period T. A theorem of boundedness of the solutions proved by the reviewer [Atti Accad. Italia Mem. Cl. Sci. Fis. Mat. Natur. (6) 11 (1940), 633–695; MR 3, 41; MR 8, 208] is used consistently, and practical criteria for stability are obtained.

Mitra, M. 5458

Disturbance produced in an elastic half-space by impulsive normal pressure.

Proc. Cambridge Philos. Soc. **60** (1964), 683–696.

The displacement produced in an elastic half-space by a uniform impulsive pressure acting over a circular portion of the surface has been obtained in terms of definite integrals. For the surface, terms representing the P-waves and the Rayleigh-waves were found. The equations obtained are quite complex and appear to reproduce many of the features of seismic disturbances.

W. J. Pierson, Jr. (New York)

Subba Rao, V.; Nigam, S. D. 5459

Wave propagation in rotating elastic media.

Mathematika **11** (1964), 29–38.

Lighthill's method [Philos. Trans. Roy. Soc. London Ser. A 252 (1960), 397–430; MR 26 #5844] is used to study the propagation of waves due to a localised disturbance, oscillating with period $2\pi/\omega$, in an elastic medium rotating with angular velocity Ω. The application is straightforward and nothing essentially new emerges, but there is virtually no discussion of the basic equations of motion on which the whole theory rests. This is unfortunate because it is not immediately clear why the acceleration of the displacement vector $\mathbf{V}$ has been written in the form

$$(1)\qquad \frac{\partial^2 \mathbf{V}}{\partial t^2} + 2\mathbf{\Omega} \wedge \frac{\partial \mathbf{V}}{\partial t} + \mathbf{\Omega} \wedge (\mathbf{\Omega} \wedge \mathbf{r})$$

instead of

$$\frac{\partial^2 \mathbf{V}}{\partial t^2} + 2\mathbf{\Omega} \wedge \frac{\partial \mathbf{V}}{\partial t} + \mathbf{\Omega} \wedge (\mathbf{\Omega} \wedge (\mathbf{r} + \mathbf{V})).$$

In the paper $\mathbf{r}$ is undefined but presumably it is the undisturbed position of the element whose displacement vector is $\mathbf{V}$. Various arguments can be given justifying (1) but they require $\omega^2 \gg \Omega^2$, which invalidates many of the conclusions of the paper.

Favre, Henry 5462

Sur la propagation des vibrations transversales le long d'une barre prismatique viscoélastique à comportement linéaire.

J. Mécanique **3** (1964), 251–276.

This paper deals with the theory of lateral vibrations of viscoelastic beams, where, besides the lateral inertia, the influence of the inertia of rotation and the influence of the shearing forces are taken into account, as in the elastic case treated by Lord Rayleigh and Timoshenko. In the case of a first-order viscoelastic law between stresses, strains and their time derivatives, the basic equations of the problem are two simultaneous linear partial differential equations, one of the fourth order, the other of the third order for the lateral displacement and the angle of rotation. For the applications, and especially for the integration, it is necessary to distinguish between long, mean and short waves on one hand, and to specialize the constitutive equations on the other hand, so that certain terms can be neglected and the angle of rotation can be easily eliminated. In all the cases the discussion of the problem turns around a biquadratic characteristic equation. Thus, the paper, as an earlier one of the author on the longitudinal waves along conical rods [same J. **2** (1963), 135–152; MR **27** #4426], gives an interesting and carefully studied view of the behavior of certain types of one-dimensional viscoelastic waves.

Mișicu, M. 5463

Theory of viscoelasticity with couple stresses and some reductions to two-dimensional problems. I.

Rev. Méc. Appl. 8 (1963), 921–952.

The author generalizes the governing equations of the linearized theory of dynamic viscoelasticity to include the effects of couple stresses. The equations thus obtained are used to set up the boundary-value problems for plane strain and generalized plane stress. The latter are then reformulated in terms of complex variables.

Shinozuka, M. 5464

Stresses in an incompressible viscoelastic-plastic thick-walled cylinder.

AIAA J. **2** (1964), 1800–1804.

Author's summary: "Stresses and strains in an incompressible viscoelastic-plastic thick-walled cylinder subject to an internal pressure are determined under conditions of infinitesimal plane strain. The internal pressure is assumed to increase monotonically as a function of time approaching a finite final value. With the von Mises yield condition, which is identical with the Tresca condition under the assumption of plane strain and incompressibility, the problem is statically determined; the stresses can be determined without the knowledge of the strains, which in the present problem have to be evaluated by solving an integral equation. A numerical example is given for a material with deviatoric stress-strain relations characteristic of a standard solid with yield limit in which the integral equation is reduced to a differential equation."

Existenzsatz für begrenzte Potentialströmungen mit Totwasser um ein vorgegebenes Hindernis.

S.-B. Sächs. Akad. Wiss. Leipzig Math.-Natur. Kl. **105**, *no.* 7, 52 *pp.* (1964).

The existence and uniqueness of plane steady flow of an incompressible inviscid fluid with dead-water wake about a certain class of obstacles was proved by Leray [Comment. Math. Helv. 8 (1935), 149–180; ibid. 8 (1935), 250–263]. The present report extends this proof to flows bounded by a straight wall. The flow region is mapped on the interior of a half-ring. The Dirichlet problem for the interior of the half-ring is solved in definite-integral form. Leray's method, involving application of a fixed-point theorem of functional equations in Banach space, is then followed, and the existence theorem is proved.

Solution générale des écoulements incompressibles potentiels du type laplacien $u=\vec{\nabla}\varphi$ et du type de Poisson $u=K(x,y,z)\vec{\nabla}\varphi$.

C. R. Acad. Sci. Paris **259** (1964), 295–296.

A relation is obtained between the potential φ and the metric coefficients of the orthogonal curvilinear coordinate system of which the surfaces $\varphi=\text{const}$ form one family for the case when the velocity u is solenoidal. The author is apparently unaware that an orthogonal curvilinear coordinate system cannot, in general, be constructed because φ must satisfy a certain third-order partial differential equation in order that the system exists.

Marris, A. W. 5469

Generation of secondary vorticity in a stratified fluid.

J. Fluid Mech. **20** (1964), 177–181.

Author's summary: "The theory is presented for the generation of secondary vorticity in a stratified fluid. The analysis is a generalization of original work of Hawthorne

[Proc. Roy. Soc. London Ser. A 206 (1951), 374–387; MR 13, 177]. It is shown that for an incompressible, inviscid and non-diffusive flow, a flow-wise vorticity component will be generated in a curved stream when a density gradient exists in the direction of the bi-normal to the streamline."

Hayes, Wallace D. 5470

Rotational stagnation point flow.

J. Fluid Mech. **19** (1964), 366–374.

This paper presents a solution for the flow of an inviscid incompressible fluid bounded by the fixed plane $z=0$. The components of velocity parallel to the plane are assumed to vary linearly in x and y, and the author derives a set of differential equations to determine the dependence on z. In general, the solution of these equations is non-analytic at $z=0$, and as a consequence the tangential vorticity becomes infinite on this plane. The stagnation streamline approaches the plane tangentially, in contrast to the two-dimensional case in which it meets the plane at a finite angle. Boundary-layer equations corresponding to the inviscid flows are also given.

The author concludes that, in a general three-dimensional flow past a body, vorticity in the mainstream will cause the flow near a stagnation point to behave as described in his solution. The opinion of the reviewer is that this is doubtful, since a real flow will involve quadratic and higher-order terms in x and y, and these terms contribute to the author's differential equations. In fact, if the velocity is analytic, but rotational, near the stagnation point, then it is locally two-dimensional.

Olmstead, W. E.; Raynor, S. 5473

Depression of an infinite liquid surface by an incompressible gas jet.

J. Fluid Mech. **19** (1964), 561–576.

The problem of small angle depressions in a liquid surface due to an impinging two-dimensional potential jet is treated by conformal mapping techniques and a method due to Birkhoff and Zarantonello [*Jets, wakes and cavities*, Academic Press, New York, 1957; MR 19, 486]. The real and imaginary parts of the Levi-Civita function are shown to be related by an integral transform on one part of the liquid-surface profile, and by straightforward substitutions this can be rewritten as a finite Hilbert transform. The second boundary condition along the gas-liquid interface, after some manipulation, reduces the problem to the solution of the following non-linear singular integral equation

$$\bar{\tau}(r) = -\frac{1}{3}\lambda(1-r)\frac{d}{dr}\,{}^{*}\!\!\int_{-1}^{+1}\left(\frac{1-r}{1-s}\right)^{1/2}\frac{\left[\dfrac{2^{1/2}-(1-s)^{1/2}}{2^{1/2}+(1-s)^{1/2}}\right]}{(s-r)}e^{3\tau(s)}\,ds,$$

where the asterisk denotes the Cauchy principal integral. An asymptotic solution for the case in which the liquid surface profile approaches a straight line is derived and is relevant to the situation of low jet velocity. The non-linear integral equation is approximated by a set of non-linear algebraic equations by using the trapezoid rule and finite differences. These equations are solved by a method of repeated linear corrections and the liquid surface profiles and the free stream-lines of the jet are calculated in four cases. The authors conclude that for the cases they consider the physical model of a potential flow gas jet impinging on a motionless liquid surface yields results which compare favourably with experimental work of Banks and Chandrasekhara [J. Fluid Mech. **15** (1963), 13–34], in particular, verifying the appearance of lips on the liquid surface which become more prominent and more slightly outward as the centre line depression increases.

K. B. Ranger (Toronto, Ont.)

Stewartson, K. 5474

Falkner-Skan equation for wakes.

AIAA J. **2** (1964), 1327–1328.

The Falkner-Skan equation

$$f''' + ff'' + \beta(1-f'^2) = 0$$

is considered, subject to the boundary conditions $f(0)=f''(0)=0$, $f'(\infty)=1$, appropriate for the flow in a wake. The author seeks the dependence of $f'(0)$ on β as $\beta\to 0-$. Following a conjecture that $f'\to f_0'$ as $\beta\to 0-$ apart from a shift of origin of the independent variable, where f_0 is the solution for $\beta=0$ satisfying $f_0'(\infty)=1$ and $f_0'(-\infty)=0$, a small-perturbation analysis is used to obtain the estimate

$$\beta \approx -q^3\left[\frac{-2f'(0)}{\pi}\right]^{1/2}\exp\left[-qb+\frac{q^2}{2f'(0)}\right],$$

where $q=0.876$ and $b=2.014$. *M. G. Hall* (Farnborough)

Application of quasilinearization to boundary-layer equations.

AIAA J. **2** (1964), 1860–1862.

This note describes a straightforward application of the so-called quasilinearization method (monotonically convergent generalized Newton method) to the Falkner-Skan equation $f'''+ff''+\beta(1-f'^2)=0$, $f(0)=f'(0)=0$, $f'(\infty)=1$. The computational results show that the process gives good results even when starting from relatively poor initial approximations. *W. C. Rheinboldt* (Silver Spring, Md.)

Morse, T. F. 5476

Secular behavior in an analysis of damped standing waves in a gas.

Phys. Fluids 7 (1964), 1691–1695.

Author's summary: "By considering multiple time scale behavior in the viscous damping of a one-dimensional wave, it has been shown how secularities (terms growing unbounded in time) present in the Hilbert solution of this problem may be eliminated. The method of time scales and the accompanying freedom to remove secular terms overcomes in part the major disadvantage of the Hilbert procedure which requires a periodic renormalization of the lowest order initial conditions. This method, which has proved most useful in nonequilibrium statistical mechanics, provides a link between the Hilbert and Chapman-Enskog treatment of a simple hydrodynamic problem."

Bush, William B. 5477

Local similarity expansions of the boundary-layer equations.

AIAA J. 2 (1964), 1857–1858.

H. J. Merk [J. Fluid Mech. 5 (1959), 460–480] developed asymptotic expansions for the incompressible boundary-layer equation

$$f_{\eta\eta\eta}+ff_{\eta\eta}+\beta(\xi)[1-(f_\eta)^2] = 2\xi[f_\eta f_{\eta\xi}-f_\xi f_{\eta\eta}],$$

$$f(\xi,0)=f_\eta(\xi,0)=0,\quad f_\eta(\xi,\infty)=1.$$

This note shows that an additional contribution of first order in ξ should be considered in these expansions. Using this fact, a new approximate solution for the shear function at the wall is developed. The resulting correction turns out to be most important for small values of β.

W. C. Rheinboldt (Silver Spring, Md.)

Devan, Leroy; Oberai, Madan Mohan 5478

Approximate solution of second-order boundary-layer equations.

AIAA J. 2 (1964), 1838–1840.

The second-order boundary-layer equation derived by M. Van Dyke [J. Fluid Mech. 14 (1962), 161–177; MR 26 #5824; ibid. 14 (1962), 481–495; MR 26 #5825] is solved by using the von Kármán-Pohlhausen method. The second-order solution is divided into three parts accounting for the effects of displacement, curvature, and external vorticity. Polynomials of fourth degree are used to approximate each of these second-order solutions as well as the first-order solution. As an illustrative example, the flow near a stagnation point is worked out, and reasonable agreement is obtained when compared with results from existing calculations.

Rogers, M. H.; Lance, G. N. 5479

The boundary layer on a disc of finite radius in a rotating fluid.

Quart. J. Mech. Appl. Math. 17 (1964), 319–330.

Authors' summary: "The axisymmetric boundary layer on a fixed circular disc of radius a due to a rotating fluid has been examined numerically. A series expansion solution, starting at the outer edge of the disc, is found to match the similarity solution due to Bodewadt at $r=\frac{1}{2}a$. Numerical solutions, obtained by using the series expansion approach, are also given for cases in which the disc rotates in the opposite sense to that of the external flow. These make it appear likely that the boundary layer erupts at the axis of symmetry, although the possibility of separation before the axis is reached cannot be ruled out."

Interactions of heat transfer and hypersonic boundary layers under highly favorable pressure gradients.

Proc. 1963 Heat Transfer and Fluid Mech. Inst. (*Calif. Inst. Tech., Pasadena, Calif.*, 1963), *pp.* 44–57. *Stanford Univ. Press, Stanford, Calif.*, 1963.

Author's summary: "The boundary layer in a hypersonic nozzle is studied. The main interest lies in the interesting interaction between the wall thermal condition and the development of the boundary layer itself. It is shown that for reasonable nozzle shapes and for high values of γ, the Falkner-Skan pressure gradient parameter, β, is generally large. Taking advantage of this observation, the boundary layer on the nozzle walls is analyzed in details by means of the method of inner and outer expansions."

Duty, R. L.; Reid, W. H. 5481

On the stability of viscous flow between rotating cylinders. I. Asymptotic analysis.

J. Fluid Mech. 20 (1964), 81–94.

The stability of Couette flow, in the case that the gap divided by the mean radius is small, is considered for the mathematically difficult situation $\mu=\Omega_2/\Omega_1\to-\infty$ (here Ω_1 and Ω_2 are the angular velocities of the inner and outer cylinders, respectively). The analysis is based on an asymptotic method in which the Taylor number is treated as a large parameter. The solutions are expressed asymptotically in terms of the solutions of the comparison equation $y^{(vi)}=xy$. The limiting values of the critical Taylor number and the critical wave number as $\mu\to-\infty$ are determined. It is found that there exists an infinite number of cells between the cylinders, but that the amplitude of the secondary motion in all but the innermost cell is small.

R. C. DiPrima (Rehovot)

Harris, D. L.; Reid, W. H. 5482

On the stability of viscous flow between rotating cylinders. II. Numerical analysis.

J. Fluid Mech. 20 (1964), 95–101.

The classical problem of the stability of Couette fluid, mentioned in the previous review [#5481], is treated by direct numerical procedures. The eigenvalue problem is solved by choosing a fundamental set of solutions so that the boundary conditions at one end are satisfied; the eigenvalue is determined by trial and error so that after integrating the remaining solutions to the other end-point, the boundary conditions there are satisfied. Results are given for the small-gap problem for a range $-3<\mu<1$ for the first mode, and $-2<\mu<1$ for the second mode [see #5481 above].

Plesset, Milton S.; Hsieh, Din-Yu 5483

General analysis of the stability of superposed fluids.

Phys. Fluids 7 (1964), 1099–1108.

Two compressible, inviscid fluids in a gravity field are

separated by a plane interface and move parallel to the interface. The stability analysis is made based on the small-perturbation approach. The dispersion relation or the characteristic equation is found to involve Whittaker functions. The familiar Rayleigh-Taylor and Kelvin-Helmholtz criteria for stability are obtained in the incompressible limits. In the subsonic case it is found that compressibility decreases the range of stability. In the supersonic case it is found that Landau's stability holds only for one disturbance mode and that stratification, in general, leads to instability of the interface. The paper concludes with a simple physical discussion of the Kelvin-Helmholtz stability problem. *L. N. Tao* (Chicago, Ill.)

Simon, R. 5484

Stability of step shocks by the normal-modes method.

J. Mécanique **3** (1964), 165–172.

A stationary normal shock in a uniform stream of homogeneous fluid with an arbitrary equation of state is considered to be perturbed from its undisturbed position, $x=0$, to $x=\operatorname{Re} C_0 \exp i(\sigma t+ly+mz)$, with corresponding perturbations to the up and downstream flow quantities.

When the flow is supersonic ahead and subsonic behind the shock, it is concluded that a necessary and sufficient condition for stability is that F_s, a certain function of the unperturbed downstream fluid quantities, should be positive, in agreement with Erpenbeck [Phys. Fluids **5** (1962), 1181–1187; MR **27** #5449]. The conclusion is also stated to hold for oblique shocks if the normal flow is considered, which seems obvious. As the equation of state is arbitrary, cases other than supersonic ahead, subsonic behind, may arise; these are all stated to lead to instability. *H. C. Levey* (Perth)

Thomas, R. H.; Walters, K. 5485

The stability of elastico-viscous flow between rotating cylinders. II.

J. Fluid Mech. **19** (1964), 557–560.

From the authors' summary: "The work of Part I [same J. **18** (1964), 33–43; MR **28** #1855] is extended to include highly elastic liquids. To facilitate this, use is made of the orthogonal functions used by Reid [Proc. Roy. Soc. London Ser. A **244** (1958), 186–198; MR **19**, 1119] in the associated Dean-type stability problem. It is shown that the critical Taylor number decreases steadily as the amount of elasticity in the liquid increases, until a transition is reached, after which the roots of the determinantal equation that determines the Taylor number as a function of the wave-number become complex. It is concluded that the principle of exchange of stabilities may not hold for highly elastic liquids." *D. W. Dunn* (Ottawa, Ont.)

Lettau, H. 5486

A new vorticity-transfer hypothesis of turbulence theory.

J. Atmospheric Sci. **21** (1964), 453–456.

After criticizing the momentum-transfer and vorticity-transfer hypotheses, the author proposes a new expression for $\mathbf{c}'$, the vorticity change caused by particle displacement $\mathbf{r}'$:

$$\mathbf{c}' = -\mathbf{r}'\cdot\nabla\bar{\mathbf{c}}+\bar{\mathbf{c}}\cdot\nabla\mathbf{r}',$$

where $\bar{\mathbf{c}}$ is the mean vorticity. The first term is that of the ordinary vorticity-transfer theory, while the second represents adjustment of the particle vorticity toward the local value. An equivalent form is $\mathbf{v}'=\mathbf{r}'\times(\nabla\times\bar{\mathbf{V}})$, from which Reynolds stresses can be calculated in terms of quantities such as $\overline{x'z'}$. The von Kármán constant appears as $|\overline{x_z'y_y'}|^{1/2}$. For flow in a constant-stress layer near a wall, consistency of the new hypothesis with the basic mechanics requires a logarithmic velocity profile. Brief mention is made of application to flow with bi-directional shear and to large-scale motion in the atmosphere. *A. A. Townsend* (Cambridge, England)

Pao, Yih-Ho 5487

Statistical behavior of a turbulent multicomponent mixture with first-order reactions.

AIAA J. **2** (1964), 1550–1559.

From the author's summary: "The dilute turbulent concentration fields of a multicomponent mixture with any type isothermal first-order reaction are investigated. For certain given initial conditions, the reacting concentration fields are related to the nonreacting case provided that the diffusivities of all species with respect to the main solution are equal. Known results of turbulent mixing are used to estimate the rate of decay and/or growth of the reacting turbulent concentration fields. For the case of stationary turbulence with first-order reactions and with nonequal diffusivities, where the Reynolds number and Peclet number are large, the small-scale structure of the turbulent concentration fields are investigated under the assumption of local isotropy and local homogeneity. A unified concept for spectral transfer at large wave numbers is proposed which, in essence, is a generalization of the Onsager-Corrsin spectral transfer concept. With this unified spectral transfer concept, as well as other concepts, the reacting concentration spectrum functions are deduced for three-wave number ranges: (1) the inertial-convective range, (2) the viscous-convective and viscous-diffusive range for large Schmidt numbers, and (3) the inertial-diffusive range for small Schmidt numbers." *P. G. Saffman* (Pasadena, Calif.)

Rotta, J. C. 5488

Incompressible turbulent boundary layers. (French summary)

Mécanique de la Turbulence (Marseille, 1961), pp. 255–285. (1 plate) Éditions Centre Nat. Recherche Sci., Paris, 1962.

Author's summary: "A brief outline of the present knowledge of turbulent boundary layers in two-dimensional incompressible flow is given. In particular, the attention is directed towards the different behaviour of the flow near the wall and in the outer part of the layer. The applicability of the two-layer conception is reviewed and the problem to predict the development of the turbulent boundary layer in an arbitrarily given pressure field is discussed."

★Some variational problems in gas dynamics [Некоторые вариационные задачи газовой динамики].

Vyčisl. Centr Akad. Nauk SSSR, Moscow, 1963. 142 *pp.* 0.71 *r.*

This monograph deals with variational problems in steady supersonic gas dynamics, e.g., minimal drag bodies, maximum thrust nozzles, etc. It is divided into six chapters.

Chapter 1 gives the general equations of gas dynamics and a detailed discussion of the steady flow characteristics. Chapter 2 considers variational problems for shockless flows in a fixed region; necessary conditions for extrema are derived, and solution methods for variational problems are presented.

Chapter 3 considers variational problems for flows with shocks, and Chapter 4 discusses minimal drag bodies; in both these chapters, however, only bodies with no shocks at the front-most point are dealt with. Bodies with attached nose shocks are studied in Chapter 6.

Chapter 5 deals with variational problems involving nozzles and jets, i.e., internal flows and axi-symmetric free-streamline flows.

The bibliography (25 items) contains Soviet works on the subject and many Western references on optimal nozzles, but none on minimal drag bodies.

C. K. Chu (New York)

Fisher, Donald D. 5490

Calculation of subsonic cavities with sonic free streamlines.

J. Math. and Phys. **42** (1963), 14–26.

This paper gives the solution of the compressible Riabuchinsky flow by means of numerical methods in the hodograph plane. Consider a two-dimensional, everywhere-subsonic flow, with given Mach number and parallel streamlines at infinity. A Riabuchinsky cavity consists of two flat plates orthogonal to the flow, with a cavity in between bounded by two free streamlines. The problem treated in this paper is to determine the cavity ratio such that the flow is everywhere subsonic, except on the free streamlines where it is required to be sonic.

The equations are transformed into the logarithmic hodograph plane. The resulting equations are linear, and there is no difficulty with the boundary conditions in the hodograph plane as is usually encountered. However, the sonic line is singular in that the elliptic differential equations become parabolic there. The solution is calculated in the hodograph plane by an appropriate finite-difference scheme which takes into account this singularity. The solutions obtained agree closely with those of Helliwell and Mackie [J. Fluid Mech. **3** (1957), 93–109; MR **19**, 914; Quart. J. Mech. Appl. Math. **12** (1959), 298–313; MR **22** #2234] using the Tricomi approximation, while the von Kármán-Tsien approximation is shown to yield inferior accuracy in this problem. This problem is of interest in the solution of the extremal problem of determining the maximum critical Mach number profile due to Gilbarg and Shiffman [J. Rational Mech. Anal. **3** (1954), 209–230; MR **15**, 756]. *C. K. Chu* (New York)

Borisov, V. M. 5491

On the optimal shape of bodies in a supersonic gas flow. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **3** (1963), 786–793.

Variational methods are used to determine the optimum shape of a flat-nosed body of revolution producing minimum wave resistance in a uniform supersonic stream. The problem is solved, firstly, for frozen flow and, secondly, for equilibrium flow. Meridian sections of the optimum body shapes are calculated in two representative cases.

Luboński, Jan 5492

Hypersonic, plane Couette flow in rarefied gas. (Polish and Russian summaries)

Arch. Mech. Stos. **14** (1962), 553–560.

Plane Couette flow of a rarefied gas is treated under the assumption that the walls slide relatively to each other with a speed much greater than the thermal speed of the molecules. The gas is treated as a mixture of three types of molecules; those having just left one wall, those having just left the other wall, and those having experienced multiple collisions. Under the assumption of small gap and large velocity, the collision integrals in the Boltzmann equation for each of the three species are either neglected or replaced by simple expressions. The three simultaneous equations are then solved iteratively, the zeroth order term being free molecular flow. The paper does not compare its results with the standard Couette flow results available in the literature in the limit of high-wall velocities. *C. K. Chu* (New York)

Sjagaev, V. F. 5493

A method of solving numerically a problem of the flow of a supersonic gas around conical bodies. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **3** (1963), 742–754.

The problem of supersonic flow past a yawed cone is solved by a numerical finite-difference process. In effect, the unknown conical shock wave is represented as one of a two-parameter family of surfaces. The calculation starts with an assumed position of shock wave, providing enough data for a Cauchy problem, the solution of which determines a certain body surface. The assumed shock position is adjusted successively until the body surface coincides with the actual cone to the desired degree of accuracy. Calculations for a circular cone agree well with other theoretical results and with experiment.

★Theory of point explosions [Теория точечного взрыва].

Gosudarstv. Izdat. Fiz.-Mat. Lit., Moscow, 1961. 332 *pp.* 1.22 *r.*

This book is a sequel to *Similarity and dimensional methods in mechanics* by L. I. Sedov [Academic Press, New York, 1959; MR **21** # 6840]. The first two chapters recapitulate much of the basic theory set out in the earlier volume. The third chapter introduces the main topic, namely, the approximate treatment of non-self-similar problems as linear perturbations of self-similar problems. The remaining chapters deal with practical problems of this type, and these fall into two main categories. First, there are problems in which self-similarity is violated due to consideration of more than two independent physical parameters (e.g., point explosions when account is taken of the pressure in the undisturbed medium). In the second class of problems, additional independent variables are

introduced (e.g., point explosions in a medium with a density gradient or in a moving medium). A wide variety of problems of the first kind are considered in detail; these include not only unsteady flow problems but also, using the blast wave analogy, steady hypersonic flow problems. Fewer solutions of the second type are available. The book is lucidly written and is recommended to those active in research in gas dynamics.

M. Holt (Berkeley, Calif.)

Sichel, Martin 5495

Structure of weak non-Hugoniot shocks.

Phys. Fluids **6** (1963), 653–662.

Shock structure is investigated in cases when the shock thickness is comparable with its curvature, so that the effects of tangential gradients of velocity, pressure, etc., can no longer be neglected. The author investigates this problem in transonic flow, solving the Navier-Stokes equations by means of an expansion in terms of a transonic parameter. The governing equation combines the characteristics of Burgers' equation and the transonic small disturbance equation. The structure of weak shocks is determined by a similarity solution of this equation. Expressions for the velocity components inside the shock are derived.

Gerber, Henry 5496

Acoustic properties of fluid-filled chambers at infrasonic frequencies in the absence of convection.

J. Acoust. Soc. Amer. **36** (1964), 1427–1434.

Author's summary: "The general equation of heat conduction inside a fluid-filled chamber takes two forms, which correspond to zero and infinite acoustic impedance of the driving source, respectively. By means of a simple transformation, it is possible to convert this equation to the standard diffusion equation with simple initial and boundary conditions. Special solutions to this equation are used to derive transfer functions E, which relate the impressed temperature to the resultant average temperature. The equation of state of the fluid is then used to determine the relationships between pressure and volume changes in terms of E. These relationships take the form of two different acoustic impedances Z_p and Z_v, which correspond to zero and infinite source impedance, respectively. In general, the chamber impedance is a function of Z_p, Z_v, and the external impedances. The above results can be used to extend the validity of acoustic circuit diagrams to zero frequency. The infrasonic acoustic impedance is an R-C network, and numerical values of the components can be calculated in a simple manner."

Gerber, Henry 5497

Calculation of dynamic-pressure changes in the presence of free convection.

J. Acoust. Soc. Amer. **36** (1964), 1435–1441.

Author's summary: "If a piston compresses and heats gas in a chamber that is larger than a few cubic inches, then the heat exchange between the gas and the wall is governed by convection. The simultaneous, nonlinear partial differential equations of free convection are given. Application of dimensional analysis to these equations indicates that the convection process can be described in terms of three dimensionless variables: the Grashof number, the Prandtl number, and the thermal-diffusion number. A simplified model of the process of free convection is derived and it is shown that the geometrical constants of the model can be expressed in terms of the Grashof and Prandtl numbers. The chamber length l and the boundary-layer thickness l_b play a key role. Mathematical solutions for the chamber pressure that follows a step piston displacement are derived and they agree within 1% with the measured pressure."

Atabek, H. B. 5498

Start-up flow of a Bingham plastic in a circular tube.

Z. Angew. Math. Mech. **44** (1964), 332–333.

A solution is presented for the title problem for a step function pressure gradient loading. As is usual, the Bingham material is assumed rigid for stresses below the critical stress. This assumption leads to minor difficulties in the representation of the stress field in the rigid core of the material during acceleration.

No numerical results are given, which is unfortunate since the solution is given in a Fourier-Bessel series which is not readily evaluated numerically.

On the effects of variable suction on the steady laminar flow due to rotating bodies of revolution in non-Newtonian fluid. (German and Russian summaries)

Z. Angew. Math. Mech. **44** (1964), 193–202.

Author's summary: "The effects of variable suction on the steady laminar flow within the boundary layer due to a rotating sphere, prolate and obalte spheroids in non-Newtonian fluid are investigated. The secondary flow patterns in a meridian section past these bodies of revolution are represented graphically. Displacement and momentum thicknesses along the bodies of revolution are evaluated."

Singh, Devi 5501

Flow of visco-elastic Maxwell fluid through concentric circular cylinders.

Z. Angew. Math. Mech. **44** (1964), 330–331.

A Maxwell fluid is a visco-elastic material in which the elastic stresses are characterized by a simple relaxation time. In this paper, the author treats the flow of such a fluid between two concentric rotating cylinders when the

applied pressure and angular velocity of the cylinders decay exponentially with arbitrary time constants. Solutions are obtained in terms of Bessel functions of first and second order for axial and circumferential velocity components, which are independent for axially symmetric flow. The solution is shown to have different form for large and small values of relaxation time. The interested reader should note that the time derivative of the pressure has been omitted from Equation 2.3.

{Reviewer's note: The change of form of the solution with increasing relaxation time demonstrates the non-uniform interaction of the viscous and elastic material properties. For large relaxation time, the asymptotic form of the solution has a boundary-layer character: the viscous flow is restricted to an exponentially thin boundary layer on the pipe wall; the bulk of the material behaves elastically, moving as a solid body in the central core. In contrast, for small relaxation time, viscous effects permeate the entire flow.} *O. R. Burggraf* (Columbus, Ohio)

Agostinelli, Cataldo 5503

Forma assoluta spazio-temporale delle equazioni della magneto-fluidodinamica.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 127–152.

L'auteur établit d'abord les équations intrinsèques dans une variété spatio-temporelle à quatre dimensions pour le mouvement d'un fluide conducteur soumis à la gravitation. Les détails donnés sur cette variété et sur la mise en équation permettent l'accès de l'article à des lecteurs peu initiés. A partir de ces équations, les composantes spatiales sont ensuite isolées pour revenir à la formulation tridimensionnelle. Puis un système d'équations approchées est obtenu en négligeant dans les équations précédentes les termes d'ordre supérieur à 1 par rapport à $1/c$; par exemple, l'équation habituelle de conservation de la masse se trouve maintenant remplacée par:

$$\frac{\partial\rho}{\partial t}+\operatorname{div}(\rho\mathbf{V})-\frac{1-\epsilon\mu}{2c\mu}\operatorname{div}(\mathbf{E}\wedge\mathbf{B})=0.$$

En négligeant enfin dans le système précédent les termes qui contiennent le facteur $(1-\epsilon\mu)/(c\mu)$, on retrouve les équations usuelles. *R. Thibault* (Sotteville-lès-Rouen)

Bhatnagar, P. L.; Kumar, Ram 5504

Propagation of small disturbances in viscous and electrically conducting liquids in the presence of magnetic field.

Indian J. Math. **6** (1964), 1–19.

This paper extends the authors' results [same J. **2** (1960), 41–66; MR **22** #5976] to a fluid that is viscous and electrically conducting. *C. S. Morawetz* (New York)

Caldwell, Douglas R. 5505

Oscillating boundary layer in magnetohydrodynamics. I. Nonconducting boundary.

Phys. Fluids **7** (1964), 1062–1070.

S. Lundquist [Phys. Rev. (2) **76** (1949), 1805–1809] and B. Lehnert [ibid. (2) **94** (1954), 815–824] have investigated the generation of Alfvén waves in liquid metals. The corresponding experimental results have not agreed at all with the theoretical results. According to the author of the present paper, this discrepancy is caused by the neglect of mechanical friction (i.e., neglect of kinematic viscosity term) compared to magnetic viscosity, i.e., in other words, the main dissipative mechanism in the fluid is considered to be Joule losses, not mechanical friction. In the present paper, the author takes into consideration both the above terms and obtains as a final result a fourth-order differential equation from the Navier-Stokes equation, Ohm's law and Maxwell's equations instead of a resulting second-order differential equation.

With this in view and applying relevant boundary conditions, the author solves the problem of the oscillating non-conducting disk immersed in a fluid of infinite extent, where the direction of a constant magnetic field H_0 coincides with the axis of symmetry of the oscillating disk. The experimental measurements of the damping of such a torsional pendulum in liquid like mercury in the presence of an axial magnetic field H_0 are in nice agreement with the theoretical results up to $H_0\sim 10$ kilogauss. *K. M. Ghosh* (Belgharia)

Caldwell, Douglas R. 5506

Oscillating boundary layer in magnetohydrodynamics. II. Conducting boundary.

Phys. Fluids **7** (1964), 1338–1348.

The problem discussed in this paper is a continuation of an earlier problem discussed by the same author [#5505]. In the earlier problem the author considered hydromagnetic motion caused in an infinite fluid by an oscillating non-conducting boundary in the presence of an axial magnetic field, both theoretically and experimentally. In the present paper he discusses the general problem of the generation of Alfvén waves by an oscillating electrically conducting boundary in a fluid of finite extent in the presence of an axial magnetic field where the oscillating plate and plates bounding the fluid have arbitrary electrical conductivity. Results are given specifically for cases where the fluid region is much larger than the viscous penetration depth, but much smaller than the wavelength of Alfvén waves. According to the author, these are necessarily the experimental conditions for this oscillating viscometer since the viscous penetration depth is less than 0.04 cm at usual frequencies in mercury and the Alfvén mode wavelength is greater than a meter. The experimental data as obtained here from the above oscillating disk viscometer have given somewhat good qualitative agreement with the theoretical calculations made from the infinite plate approximation. *K. M. Ghosh* (Belgharia)

Förste J. 5507

Ein Beispiel hydromagnetischer Induktion.

Monatsb. Deutsch. Akad. Wiss. Berlin **6** (1964), 561–565.

An incompressible, viscous and electrically conducting fluid is flowing under a time-dependent pressure gradient along the annular passage formed by two concentric,

straight circular tubes. It is assumed that the magnetic force is small compared to the dynamic force ($M^2/(\mathrm{Re\ Rm})$ small; M = Hartmann number, Re = Reynolds number, Rm = magnetic Reynolds number), so that the effect of the magnetic force on the fluid motion is negligible. The effect of the fluid motion on the magnetic field is studied under the assumption that at both surfaces of the wall the magnetic lines are perpendicular to the wall at all times ($t \geq 0$).

The author proves that the above boundary-value problem for the velocity and magnetic fields possesses a unique solution for a prescribed pressure function $p = f(t)$ and that the solution tends to a limit for $t \to \infty$ if $\lim_{t\to\infty} f(t)$ exists. Furthermore, it is shown that the limit satisfies the stationary-state differential equations and can be expressed in terms of elementary functions.

Finally, the author justifies his assumption regarding the effect of the magnetic field on the motion of the fluid by indicating that the solution obtained for the magnetic field only gives rise to magnetic forces of negligible magnitudes. *I-Dee Chang* (Stanford, Calif.)

Kapur, J. N. 5508

Characterisation of axially-symmetric self-superposable hydromagnetic flows.

Bull. Calcutta Math. Soc. **54** (1962), 59–66.

The author continues the discussion initiated in two earlier papers [Appl. Sci. Res. A 8 (1958), 198–208; ibid. 9 (1959), 139–147] to obtain equations characterizing axially-symmetric self-superposable hydromagnetic flows and axially-symmetric force-free fields.

L. M. Milne-Thomson (Tucson, Ariz.)

Nikol'skii, A. A. 5509

Hyperbolic problems for magnetohydrodynamic perfect fluid flows with "frozen-in" circular magnetic field lines. (Russian. Polish and English summaries)

Arch. Mech. Stos. **14** (1962), 675–682.

The paper deals with unsteady, axisymmetric flows of an infinitely conducting incompressible fluid, linearized about some equilibrium state for which the magnetic lines of force are azimuthal. Particular solutions are sought. The governing equations are seen to be either elliptic or hyperbolic in type. Some stability criteria are given.

C. K. Chu (New York)

Wells, Daniel R. 5510

Axially symmetric force-free plasmoids.

Phys. Fluids **7** (1964), 826–832.

The theory of force-free magnetic fields is applied to equilibrium configurations of an incompressible fluid with axisymmetric motions. It is demonstrated that solutions satisfying collinear force-free flow satisfy the vorticity equation for zero viscosity. Experimental measurements of the magnetic and flow fields of the plasmoids generated by a conical θ-pinch plasma gun are shown to be in agreement with the solutions to these equations.

J. N. Kapur (Kanpur)

Uberoi, C. 5511

Gravitational instability of an infinitely extending layer of finite thickness surrounded by non-conducting material in the presence of magnetic field and rotation.

J. Indian Inst. Sci. **46** (1964), 11–27.

Stability calculations are given for a rotating layer of conductive fluid surrounded by a non-conductive fluid of different density, subjected to a magnetic field normal to the axis of rotation and including gravitational effects. Although a small perturbation method is used, the actual expressions given for this perturbation are not bounded. In these expressions and in the dispersion equation a quantity G occurs which is not defined and which does not occur in the equations of motion or in the boundary conditions. The reviewer is therefore not convinced of the validity of the results. *L. J. F. Broer* (Eindhoven)

Gheorghitza, St. I. [Gheorghiţă, Şt. I.] 5512

A generalization of the circle theorem.

Bull. Calcutta Math. Soc. **54** (1962), 97–101.

The author generalizes the reviewer's circle theorem to flow in porous media in which the non-homogeneity occurs in crossing two concentric circles. The method can be extended (with increasing complexity) to the case of three or more concentric circles and, of course, to other analogous problems in mathematical physics.

On the determination of the parameters of optically active media by optical methods. (Russian)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **17** (1964), no. 4, 125–126.

The authors show theoretically that the refractive index and the gyration constant of an optically active isotropic medium can be determined by observing the rotation of the plane of polarization of a linearly polarized light wave

when the wave is incident normally on a slab and propagates through it. The observations are performed twice: first with no external magnetic field and then with the field applied parallel to the wave vector so as to compensate for the rotation due to the natural optical activity.

Geppert, Donovan V. 5517

Free-space bounded plane-wave solutions to the Maxwell-Lorentz equations.

Phys. Rev. (2) 134 (1964), B1407–B1409.

Author's summary: "A relativistic fluid concept of electric charge is introduced, from which free-space laterally-bounded plane-wave solutions to the inhomogeneous Maxwell-Lorentz equations can be obtained in harmony with the particle-like nature of the radiation field."

Hatfield, W. B.; Auld, B. A. 5518

Method of characteristics solution for electromagnetic wave propagation in a gyromagnetic medium.

J. Math. and Phys. 43 (1964), 34–37.

The authors purport to give conditions for simple waves to exist in what is known to the reviewer as a magnetically gyrotropic medium. They then purport to show that some of these may steepen to electromagnetic shocks.

In the opinion of the reviewer this paper should be considerably revised. In the first case, when dealing with transient phenomena, as in this paper, it is not valid to speak of characteristic frequencies in relation to the resonant frequency of the medium to derive the M-H relation. What is true is that if the approximate Landau-Lifshitz equation for a ferrite magnetised to saturation has been used, then the characteristic time for the phenomena under discussion must be long compared with the characteristic time, $(\gamma H)^{-1}$, occurring in that equation, and this condition would be violated ultimately for a steepening simple wave. The characteristic equations are indeed simply derivable, though the reviewer disagrees with the result obtained for the second set. Also, no hint is given as to how the auxiliary conditions necessary for the degeneracy to simple waves are obtainable from possible initial and boundary conditions. Some other conclusions with which the reviewer does not agree are also presented, but it seems useless to pursue them in the light of the points already raised.

★Elektromagnetische Felder: Ein Lehrbuch der theoretischen Physik.

Akademische Verlagsgesellschaft Geest & Portig K.-G., Leipzig, 1960. xvi+393 *pp.* *DM* 29.50.

In the order of appearance this is after "Wellen" and "Quanten" [*Wellen*, 1958; *Quanten*, 1962; MR 27 #3275], the third volume out of six. In spite of the original announcement of the series, which intended to give common cross-sections through various special subjects, the present volume does not make a broad cross-section through classical and quantum theories from the point of view of the field concept. The slice which has been cut out after restricting the fields to electromagnetic ones is hardly different from that in conventional textbooks on classical electrodynamics. Owing to the original intention of the series, there are inevitable overlaps with other volumes. The density and current density of continuum mechanics, which are used as an illustration for the introduction of scalar and vector fields, might overlap with the announced volume on mechanics of particles, systems and continua. Various aspects of electromagnetic waves have been treated more extensively in the volume on waves and, e.g., the 4-dimensional tensor representation of the energy-momentum density-current density or the canonical formalism are only treated or mentioned there. Special relativity theory, which already had been introduced rather transparently in the volume on waves, is introduced once more along somewhat different lines, now making use of the Lorentz covariance of the electromagnetic part of the non-relativistic equations. It is not clear whether difficulties of overlap and spreading are partially due to deviations from the original intention, or that these deviations are due to difficulties in making the intended cross-sections. Anyhow, overlaps may also be instructive for the student. The presentation of the present volume is again very clear. Electrodynamics is transparently built up step by step via static and stationary systems. In every step the essential mutual relations of the generation of the electromagnetic field by discrete or continuous electric charges and currents and the action of the field on the charges and currents are carefully explained. The electromagnetic properties of matter are dealt with in a somewhat schematic way. As technical applications the modern linear and circular high-energy machines are considered. MKSA units are used. In the three volumes which have appeared up till now, the imaginary unit is denoted by j in the complex notation for electromagnetic and other classical waves, by i in the pseudo-euclidean notation of 4-dimensional Minkowski space in special relativity theory and also by i in quantum mechanics. It may make sense to use a separate notation for the pseudo-euclidean tensors, but then (contrary to what has been done in the volume on waves) the other notation should still be used in the exponentials, which describe classical waves. It seems difficult to keep friends with electrical engineers and quantum theorists all the time and to maintain consistently a different notation for classical and quantum waves, in particular, in a semi-classical treatment of, e.g., interaction between quantized electrons and classical electromagnetic waves. Such a treatment has not been given in any of the three volumes, but a justification of the different and difficult notation has neither been given. There are again many instructive problems with solutions.

H. J. Groenewold (Zbl 91, 208)

Morgan, Thomas A. 5520

Two classes of new conservation laws for the electromagnetic field and for other massless fields.

J. Mathematical Phys. 5 (1964), 1659–1660.

Recently D. M. Lipkin [same J. 5 (1964), 696–700; MR 28 #5683] studied a class of differential invariants of the free electromagnetic field which were defined in terms of a tensor of rank 3. Lipkin's invariants are bilinear in the field vectors, but involve their first partial derivatives with respect to the space-time coordinates.

The author extends Lipkin's analysis to show the existence of an infinite family of tensor differential invariants for the free electromagnetic field. A corresponding analysis is given also for free spinor fields of particles of zero rest-mass of the type studied by M. Fierz and W. Pauli [Proc. Roy. Soc. London Ser. A 173 (1939), 211–232; MR 1, 190]. {Since this work, like that of Lipkin, deals with free fields, its interpretation in terms of physical theory appears to depend on the physical content which can be attributed to the Cauchy initial-value problem as applied to these fields.} *E. L. Hill* (Minneapolis, Minn.)

Petit, Roger; Cadilhac, Michel 5521

Étude théorique de la diffraction par un réseau.

C. R. Acad. Sci. Paris **259** (1964), 2077–2080.

Die Autoren behandeln das Problem der Beugung einer ebenen, senkrecht einfallenden elektromagnetischen Welle, deren $\mathfrak{E}$-Vektor parallel zur z-Achse gerichtet ist, an einer leitenden, periodisch verformten Ebene $y=f(x)$, $-\infty<x<\infty$, $-\infty<z<\infty$, mit $f(x+d)=f(x)$. Schreibt man die z-Komponente des Gesamtfeldes in der Form $E=E^i+E^d$ mit $E^i(x,y)=e^{-iky}$, so ergibt sich für $E^d(x,y)$ die folgende mathematische Randwertaufgabe. Gesucht ist: $E^d(x,y)$ in $y>f(x)$, $-\infty<x<\infty$, mit

$$\Delta E^d+k^2\cdot E^d=0,\quad E^d[x,f(x)]=-E^i[x,f(x)]=g(x),\quad -\infty<x<\infty,$$

E^d enthalte für $y\to+\infty$ nur auslaufende, beschränkte Wellen. Wegen $E^d(x+d,y)=E^d(x,y)$ läßt sich $E^d(x,y)$ in eine Fourierreihe entwickeln, die jedoch im gewöhnlichen Sinne nur für $y>\max_{-\infty<x<\infty}f(x)$, $-\infty<x<\infty$, Gültigkeit hat. Die Autoren geben ein Verfahren an, die Lösung zu $\tilde{E}(x,y)$ in das Gebiet $y<f(x)$, $-\infty<x<\infty$, fortzusetzen. Längs der deformierten Ebene $y=f(x)$ findet wegen der Randbedingung ein stetiger Anschluß statt, aber es muß zugelassen werden, daß $\partial\tilde{E}/\partial y$ dort Sprünge besitzt, deren Höhen vorerst unbekannt sind. Demzufolge soll die periodische Funktion $\tilde{E}(x,y)$ der inhomogenen Wellengleichung $\Delta E+k^2\cdot E=2ik\cdot\varphi(x)\cdot\delta[y-f(x)]$ genügen, wobei $\delta(u)$ das Dirac-Maß bezeichne. $\tilde{E}(x,y)$ hat dann die Fourierentwicklung

$$\tilde{E}(x,y)=\int_0^d R[x-x',y-f(x)]\varphi(x')\,dx',$$

$$R(x,y)=\frac{kK}{2\pi}\sum_{n=-\infty}^{\infty}\frac{\exp[inKx+i\chi_n|y|]}{\chi_n},$$

$$\chi_n=\sqrt{(k^2-n^2K^2)},\qquad K=\frac{2\pi}{d}.$$

$\varphi(x)$ muß dann der Integralgleichung

$$\tilde{E}[x,f(x)]=\int_0^d R[x-x',f(x)-f(x')]\varphi(x')\,dx'=g(x),\quad 0<x<d,$$

genügen, welche einen symmetrischen Kern besitzt. Es werden dann noch einige Spezialfälle der Entwicklung von $\tilde{E}(x,y)$ diskutiert. *E. Meister* (Saarbrücken)

Wirgin, Armand 5522

Considérations théoriques sur la diffraction par réflexion sur des surfaces, quasiment planes, applications à la diffraction par des réseaux.

C. R. Acad. Sci. Paris **259** (1964), 1486–1488.

Der Autor diskutiert kritisch eine Formel von Lord Rayleigh [Proc. Roy. Soc. London Ser. A 79 (1907), 399–416], die die Reflektion einer ebenen, elektromagnetischen Welle an einer periodisch deformierten, leitenden Ebene $z=f(x)$, $-\infty<x<+\infty$, $f(x+a)=f(x)$, in der Form

$$(1)\quad U(x,z)=U_i(x,z)+\sum_{n=-\infty}^{\infty}C_n\exp\left\{i\left[\left(k\sin\theta+\frac{2n\pi}{a}\right)x+\kappa_nz\right]\right\}$$

mit $\kappa_n=\sqrt{(k^2-(k\sin\theta+2n\pi/a)^2)}$ und

$$U_i(x,z)=\exp[ik(x\sin\theta-z\cos\theta)]$$

beschreibt. Unter Verwendung der Kirchhoff-Helmholtzschen Integraldarstellung für das Streufeld $U_s(x,z)$ in $z>f(x)$, $-\infty<x<+\infty$, ergibt sich die Formel (1) nur für $z\geqq\max_{0\leq x\leq a}f(x)$ und

$$(2)\quad U(x,z)=U_i(x,z)+\sum_{n=-\infty}^{\infty}\left(B_n^+\exp\left\{i\left[\left(k\sin\theta+\frac{2n\pi}{a}\right)x+\kappa_nz\right]\right\}+B_n^-\exp\left\{i\left[\left(k\sin\theta+\frac{2n\pi}{a}\right)x-\kappa_nz\right]\right\}\right)$$

für $f(x)\leqq z<\max_{0\leq x\leq a}f(x)$ mit

$$(3)\quad B_n^\pm=\frac{-i}{2a\kappa_n}\int_{0\,(\pm)}^{a}\exp\left\{-i\left[\left(k\sin\theta+\frac{2n\pi}{a}\right)x'\pm\kappa_n\cdot f(x')\right]\right\}\times\frac{\partial}{\partial n}U(x',z')|_{z'=f(x')}\,dx',$$

worin $\partial/\partial n$ die Differentiation bzgl. der in das Innere von $z>0$ gerichteten Normalen auf $z=f(x)$, $-\infty<x<+\infty$, bedeutet. Formel (2) enthält mithin auslaufende und einlaufende ebene Wellen. ${}_{(\pm)}\int_0^a$ bedeutet hierbei, daß über alle x' zu intergrieren ist, für die $z>f(x')$ bzw. $z<f(x')$ ist. *E. Meister* (Saarbrücken)

Erma, Victor A. 5523

Perturbation approach to the electrostatic problem for irregularly shaped conductors.

J. Mathematical Phys. **4** (1963), 1517–1526.

Author's summary: "A simple and straightforward perturbation method for treating the electrostatic problem of a charged, irregularly shaped conductor is presented. The perturbation solution is generated starting from the zero-order solution for a charged sphere. The method consists of expanding the boundary condition in a Taylor series, which in effect transforms the boundary condition at the irregular boundary into a succession of boundary conditions to be satisfied at the surface of a sphere. The simplicity of the formalism consists further in applying, in a consistent manner, sufficient rather than necessary conditions on the successive correction potentials. First- and second-order expressions for the potential, surface charge density, and capacitance of irregularly shaped conductors, are derived explicitly, and an elementary theorem for the

first-order capacitance is obtained. A perturbation expansion for the capacitance valid to all orders is presented. The application of the method is illustrated by calculating the capacitance of several irregularly shaped conductors. Possible generalizations to more complicated boundary-value problems are indicated."

Heins, Albert E. **5524**

On diffraction by a half-plane.

J. Math. Pures Appl. (9) **43** (1964), 59–66.

A Green's function for the equation

$$u_{xx}+u_{yy}-k^2u=0$$

is determined for the half-plane. This is essentially the Sommerfeld diffraction problem with line-source excitation. An integral equation formulation is given, and this equation is solved by function-theoretic methods similar to those of the author and the reviewer [Quart. J. Math. Oxford Ser. (2) 9 (1958), 132–143; MR 21 #1508]. The integral equation is shown to be equivalent to a Hilbert problem for analytic functions in a slit plane. The solution is complicated by the necessity of considering exponential behavior at infinity. *R. C. MacCamy* (Pittsburgh, Pa.)

Evangelisti, Giuseppe **5525**

Sopra le trasformate di Laplace dei problemi di propagazione.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 211–217.

The propagation properties of a non-uniform electrical transmission line are studied by means of the Laplace transform method. Assuming the parameters of the line to be continuous functions of the position x, the general nature of the Laplace transforms $V(x,s)$ and $I(x,s)$ of the potential difference and current are investigated. It is found that the line can be characterized by four entire analytic functions of the complex variable s from which V and I can be obtained by means of rational operations. *K. Schram* (Utrecht)

The approach to a stable steady state far from the equilibrium.

Proc. Phys. Soc. **80** (1962), 962–970.

A proposal of Prigogine's is here taken up in the form of a description of the approach to a steady state, far from equilibrium, through the use of a Lyapunov function. The equations of motion of the variables are derived by the method used by Cox [Rev. Modern Phys. 22 (1950), 238–248; MR 12, 467] to derive Onsager's reciprocity relations, and are subject to the same assumptions as used in that derivation. The Lyapunov function is then shown to exist, and to reduce to the rate of entropy production relative to the rate in the steady state when the steady state is near equilibrium. An interesting consequence is deduced, restricting the oscillations of a system under certain conditions, which the authors propose as a test of the assumptions used. *A. Siegel* (Boston, Mass.)

Exponential solutions of a boundary value problem of the Helmholtz equation related to change in phase.

J. Math. and Phys. **43** (1964), 227–233.

The boundary-value problem here is one in which $T_{xx}+T_{yy}+2T_y=0$ in an angular domain $\alpha<\theta<\pi/2$, $r>0$, and T is to satisfy the conditions $T=-1$ when $\theta=\alpha$ and $T_x=0$ when $\theta=\pi/2$, together with order conditions at $r=0$ and $r=\infty$. It is a simplified case of a problem of determining steady temperatures T in a bath of liquid metal through which a heat sink in the shape of a slab travels and freezes out metal. The problem is solved by introducing the functions $S(r,\theta)=e^yT(x,y)$ and representing S by a series of terms $c_i\exp[r\sin(\theta+\beta_i)]$, then using various properties of periodic functions. Here $\nabla^2S-S=0$. In particular, if $\alpha=\pi/4$, then $T=e^{-2y}-e^{-x}e^{-y}-e^{x}e^{-y}$; if $\alpha=\pi/3$, then $T=-e^{-2y}-4e^{-y}\sinh(y/2)\cosh(x\sqrt{3}/2)$. The measure of surface heat transfer T_θ/r at the boundary $\theta=\alpha$ is examined. Uniqueness of the solution T is established. *R. V. Churchill* (Ann Arbor, Mich.)

Approximate solution of non-stationary heat conduction problems in the case of perturbation of the shape of the body. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukrain. RSR **1964**, 1136–1138.

Author's summary: "A method is given for finding the approximate solution of the plane problem of nonstationary heat conductivity for weakly strained bodies in the case when the solution of the unperturbed problem is known in the form of orthonormal functions. Using the variational method the solution of the problem is reduced to finding the temperature field in the form of a series $\sum_k a_k(\tau)\varphi_k$, the coefficients of which are determined from differential equations of the form

$$\frac{da_k}{d\tau}+k^2a_k=\frac{\varepsilon}{N_k}\Phi(\tau)."$$

Ball, J. S.; Frazer, W. R.; Nauenberg, M. 5533
Scattering and production amplitudes with unstable particles.
Phys. Rev. (2) **128** (1962), 478–494.

The aim of the paper is to find a procedure to include unstable particles in the S-matrix theory. Unstable particles are treated as resonances in the scattering of their decay products, integral equations for production amplitude being written with the help of the generalized unitarity which relates the discontinuity in the s (total energy, squared) variable of the production amplitude to the amplitudes T_{11} (scattering), T_{21} (production) and $T_{22}{}^c$, the connected three-three particle amplitude:

$$T_{21}(s_+, t, \omega_+) - T_{21}(s_-, t, \omega_+) = 2i \sum T_{21}(s_+, t', \omega_+) \times T_{11}(s_-, t'') + T_{22}{}^c(s_+, t', \omega_+, \omega_+{}'')T_{21}(s_-, t'', \omega_-{}'')$$

(t the momentum transfer, ω the pion energy). The conventional unitarity gives a relation for the simultaneous discontinuity of the amplitudes in both s and ω variables across their physical cut, and therefore cannot be used directly in deriving integral equations.

To illustrate the general procedure, the authors confine themselves to S-waves (spin and isospin neglected). Dispersion relations are written in the s variable, keeping ω fixed below its physical threshold. ω is raised afterwards, by analytical continuation, to its physical domain. Finally, the resulting coupled integral equations are reduced by an extension of the N/D method to nonsingular Fredholm integral equations, which can be solved by straightforward numerical methods.

★The complex j-plane. Complex angular momentum in nonrelativistic quantum scattering theory.
The Mathematical Physics Monograph Series.
W. A. Benjamin, Inc., New York-Amsterdam, 1964. viii + 235 *pp*. $9.00.

This monograph begins with a short introduction, in which the author outlines the motivation of the current interest in complex angular momenta and stresses the scope of this monograph ("the bulk of this book deals only with the nonrelativistic domain, where results are well-grounded and, starting from known dynamics, can be proved"). In a subsequent section the Watson-Sommerfeld-Regge transformation is introduced, and its possible relevance to high-energy scattering emphasized. Then the various properties of the S-matrix as a function of complex angular momentum are analyzed in detail from a rigorous point of view in the framework of potential scattering (Sections 3 to 15). Several examples of numerically computed Regge trajectories are also given (in Section 12), which will be quite interesting for the reader, be he a beginner or an expert in this field. Section 16 is devoted to the discussion of the scattering of two particles of spin $\frac{1}{2}$. Finally, the last two sections deal with the three-body problem, where the possibility of different analytic continuations is emphasized. The book is completed by three appendices and a very extensive bibliography which includes more than three hundred papers (almost all of them published within the last three years).

This book will be very useful to all workers in this field, because it provides a comprehensive summary of our present knowledge about the angular momentum plane in potential scattering (except for the treatment of particles with spin, where only the "spin $\frac{1}{2}$, spin $\frac{1}{2}$" case is considered). It is perhaps worth emphasizing that most of the material covered is now completely settled, so that this book is likely to remain valid and useful for some time. The major exception is probably the three-body problem, whose treatment, although quite thorough, is likely to be superseded by present and future developments.

The book is well-written and well-edited. It contains also the following reprints: S. C. Frautschi, M. Gell-Mann and F. Zachariasen [Phys. Rev. (2) **126** (1962), 2204–2218; MR **25** #3728]; K. Roberts, M. J. 5536
Negative energy moments and low energy approximations to phase shifts.
Proc. Phys. Soc. **83** (1964), 503–517.

Relations between sums of inverse powers of the bound state energies and corresponding moments of the energy derivative of the phase shifts in non-relativistic scattering by potentials of at least exponential decrease at infinity

are derived by an extension of a method due to Buslaev and Faddeev [Dokl. Akad. Nauk SSSR 132 (1960), 13–16; MR 22 #11171]. Similar relations involving positive powers were employed by the author [M. J. Roberts, Proc. Phys. Soc. 82 (1963), 594–604] to obtain high-energy approximations to the phase shifts. By employing also the present relations, improved approximations at low energies should be obtained. In the example of s-wave scattering by a Gaussian potential, they are shown to lead to better results than the effective range approximation. However, in contrast to the case of positive moments, the present relations involve coefficients that have to be determined from the asymptotic behaviour of solutions to the radial equation at low energies, so that they are more difficult to apply than the positive-moment relations.

An estimate for the wave function which is analytic with respect to the energy. (Russian)

Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1964**, no. 4, 81–82.

The negative-energy solution of the S-state Shrödinger equation is expanded in the form

$$u(E, r) = \sum_{n=0}^{\infty} (-E)^n u_n(r).$$

It is shown that

$$u_n(r) = u_0(r) \int_0^r \int_0^{r_1} \cdots \int_0^{r_{2n-1}} \left(\frac{u_0(r_2)}{u_0(r_1)}\right)^2 \times \left(\frac{u_0(r_4)}{u_0(r_3)}\right)^2 \cdots \left(\frac{u_0(r_{2n})}{u_0(r_{2n-1})}\right)^2 dr_1 \cdots dr_{2n}.$$

Upper and lower bounds are obtained for the wave function and its logarithmic derivative in terms of the zero-energy solution $u_0(r)$.

Non-elastic scattering of nucleons on nuclei and the method of quantum Green's functions. (Russian)

Vestnik Moskov. Univ. Ser. III Fiz. Astronom. **1964**, no. 4, 45–51.

Non-elastic scattering of nucleons on nuclei of the type magic plus a nucleon (or hole) at low energies is considered. In particular, the author investigates the nuclear reactions (n, n'), (p, p'), (n, p), (p, n) on a nucleus of the type magic plus a nucleon (a hole) and the nuclear reactions (d, n), (d, p), (d, np) on a magic nucleus when the energy of the incoming particles is less than that of the magic nucleus excitation. It is shown that the problem of computing the S-matrix elements is connected with finding the two-particle Green's function. No assumptions about the interaction weakness or the nuclear process mechanism are used. An approximation for the T-matrix is obtained; it allows one to find the cross-sections of the nuclear reactions without using the usual perturbation theory (the Born series). In the first approximation the non-elastic scattering of nucleons on a nucleus with one particle outside a full nuclear shell is determined by the free nucleons scattering amplitude and by the magic nucleus optical potential. The theory is compared with the zero range approximation of nuclear forces.

Acharya, R. 5539

Some consequences of "minimal" analyticity and unitarity in field theory. (Italian summary)

Nuovo Cimento (10) **27** (1963), 1151–1155.

Author's summary: "A simple proof of the incompatibility of a field theory with a finite number of processes with the principles of unitarity, minimal analyticity and positive definiteness is presented. It is further argued that such a theory also violates local commutation relations."

{The reviewer believes that the author's arguments are inconclusive on three grounds: (1) The assumption of "minimal analyticity" is not stated, so that one cannot assess its consequences; (2) The terms in Equation (2), which are written in detail above Equation (2), are not, in general, positive definite as the author states; and (3) It does not seem reasonable that CTP invariance implies "minimal analyticity" as the author states, since whatever "minimal analyticity" means, as used by the author, it has consequences for many different "crossing relations" while CTP invariance has consequences only for the single "crossing relation" in which the order of the fields is completely reversed.}

O. W. Greenberg (College Park, Md.)

Blankenbecler, R.; Goldberger, M. L. 5540

Behavior of scattering amplitudes at high energies, bound states, and resonances.

Phys. Rev. (2) **126** (1962), 766–786.

Although the Mandelstam representation displays the analyticity of the scattering amplitude in an admirable fashion, the unitarity condition is extremely awkward to deal with, especially in the high-energy, large-momentum transfer region. On the other hand, the diffractional behaviour of the scattering amplitude at high energies suggests the use of the eikonal approximation.

Starting from these points, the authors introduce an exact Fourier-Bessel representation for the scattering amplitude

$$M(s, t) = \int_0^{\infty} b\, db \{J_0(b\sqrt{-t}) H_1(b^2, s) + J_0(b\sqrt{-u}) H_2(b^2, s)\}$$

which satisfies unitarity exactly in the high-energy limit, even in the many-channel situation. If one writes $H_{\pm}(b^2, s) = H_1(b^2, s) \pm H_2(b^2, s)$ for large s, the elastic unitarity takes the simple form

$$\operatorname{Im} H_{\pm}(b^2, s) = r(s) |H_{\pm}(b^2, s)|^2$$

which permits the use of the N/D formalism.

On the other hand, this representation reduces to the eikonal approximation if one replaces H by the well-known expression $\{\exp i\chi - 1\}$, where

$$\chi_l(b^2, k) = -\frac{1}{2k} \int_{-\infty}^{+\infty} dz\, V[(z^2 + b^2)^{1/2}].$$

It is shown that the Mandelstam representation is contained as a special case. The simple form of the asymptotic unitarity permits analytical continuation to unphysical sheets, and resonance and bound states discussion is similar to the partial wave case [see also R. Oehme, Z. Physik 162 (1961), 426–437; R. Blankenbecler, M. L. Goldberger, S. W. MacDowell, and S. B. Treiman, Phys. Rev. (2) 123 (1961), 692–699].

On the number of bound states of a certain potential.

Acad. Roy. Belg. Bull. Cl. Sci. (5) **49** (1963), 1195–1205.

The one-dimensional Schrödinger equation is studied for a certain two-parameter class of potentials $V(x)$, parabolic for small x and decreasing exponentially for large x. Upper and lower bounds are placed on the number of bound states which may be formed in such a potential.

J. M. Charap (London)

Cutkosky, R. E. 5543

Expansion of the scattering matrix in terms of multiple impulsive peripheral interactions.

Nuclear Phys. **37** (1962), 57–77.

Author's summary: "A new perturbation expansion is developed for the S-matrix. Each term of the expansion corresponds to a Feynman graph which describes a multiple peripheral collision. The complete effects of the short range forces are included in the first approximation. The peripheral interaction expansion is based on the analytic properties of the ordinary perturbation expansion and may be looked upon as a rearrangement of the terms of that expansion. It provides a simple perturbation-theory picture for all the concrete results that have been derived by formulating dynamical theories in terms of dispersion relations. The Feynman graphs encountered in the peripheral interaction expansion are those of the ordinary expansion with all self-energy parts omitted. This omission is possible because each line of a graph represents a set of quanta which correspond not only to the discrete states, but also to all states lying in the continuum which have a limited angular momentum. Each vertex corresponds to an elementary interaction which has a strength equal to the appropriate exact S-matrix element. Renormalization of the successive terms of the peripheral interaction is the most complicated problem which is encountered, although it is similar to renormalization of the ordinary expansion. In the treatment of this problem one encounters all possible successive graphical contractions. With the aid of these topological constructions it is possible to state the general renormalization rule quite concisely."

Glauber, Roy J. 5545

Photon correlations.

Phys. Rev. Lett. **10** (1963), 84–86.

The quantum theory of coherence is formulated; the central idea is the identification of the coherence function with the expectation value of a normal ordered operator product. The use of the (right) eigenvectors of the annihilation operators in discussions of coherence is pointed out. Since then, the reviewer has demonstrated that this quantum theoretic treatment is equivalent to the semiclassical treatment provided the probability distribution function is replaced by a suitable distribution [same Lett. **10** (1963), 277–279; MR **27** #3315].

E. C. G. Sudarshan (Syracuse, N.Y.)

Garrido, L. M.; Sancho, F. J. 5546

Degree of approximate validity of the adiabatic invariance in quantum mechanics.

Physica **28** (1962), 553–560.

The time-dependent Schrödinger equation with a time-dependent Hamiltonian $H(t)$ determines the evolution operator $U(t)$. When the time interval $T = t_1 - t_0$ is made to grow indefinitely while the total change of $H(t)$ is fixed, $U(t)$ admits a certain asymptotic expansion in $1/T$. This paper gives such an expansion which is valid up to the $(m+1)$st order in $1/T$. The basic assumptions made are that the first m derivatives of $H(t)$ are zero at the initial and final times, and that the eigenvalues of $H(t)$ are discrete and non-degenerate and depend smoothly on t as well as on the associated one-dimensional projections (which implies, in particular, that there is no crossing between eigenvalues).

T. Kato (Berkeley, Calif.)

Garrido, L. M. 5547

Generalized adiabatic invariance.

J. Mathematical Phys. **5** (1964), 355–362.

The mathematical problem for the quantum-mechanical adiabatic theorem considered here is to find an asymptotic formula as $T \to \infty$ for the unitary operator $T_T(\tau)$ determined by the differential equation $i\hbar(d/d\tau)U_T(\tau) = TH(\tau)U_T(\tau)$, where $H(\tau)$, $0 \leq \tau \leq 1$, is a family of self-adjoint operators depending smoothly on τ. The author shows that $U_T(\tau) = R^{(1)}(\tau) \cdots R^{(l)}(\tau)\phi^{(l)}(\tau)(1 + O(T^{-l}))$, where $R^{(1)}(\tau)$, independent of T, is the "adiabatic transformation" identical with the operator deduced by the reviewer [J. Phys. Soc. Japan **5** (1950), 435–439], the $R^{(k)}(\tau)$ are determined successively by solving linear differential equations with coefficients that can be computed by formal perturbation theory (the perturbation parameter is $1/T$) from $H(\tau)$ and the previous $R^{(k)}(\tau)$, and where $\phi^{(l)}(\tau)$, a unitary operator involving rapidly oscillating phase factors, can also be computed by perturbation theory. The essential assumption is that $H(\tau)$ has a pure discrete spectrum and there is no "crossing" of eigenvalues for $0 \leq \tau \leq 1$. Various consequences of this basic formula are discussed. In particular, it is shown that $U_T(1)$ sends an eigenvector of $H(0)$ into an eigenvector of $H(1)$ within an error of $O(T^{-l})$ if the derivatives of $H(\tau)$ up to order $l-1$ are zero

for $\nu = 0$ and 1, a result obtained by the author and F. J. Sancho in an earlier paper by a less general method [#5546]. *T. Kato* (Berkeley, Calif.)

Hostler, Levere 5548

Nonrelativistic Coulomb Green's function in momentum space.

J. Mathematical Phys. **5** (1964), 1235–1240.

In a previous paper [same J. **5** (1964), 591–611] the author has given an integral representation for the non-relativistic Coulomb Green's function in coordinate space. In the present paper, the author computes the Fourier transform of his previous result. After some calculations he finds that the Fourier transform of his previous formula can conveniently be written as a sum of three terms. The first term is the non-relativistic Coulomb Green's function for a free particle. The second term is the Born approximation, i.e., the result obtained as a first correction term in a power series expansion in Z_α, where α is the fine structure constant and Z is the nuclear charge. The third term is considerably more complicated than the others. It is exhibited both in terms of an integral representation and also evaluated explicitly in terms of hypergeometric functions. In this way, the author obtains a closed form for the momentum-space Green's function. At the end, the author verifies that his result has the correct analyticity properties as a function of the complex energy. *G. Källén* (Lund)

Kenschaft, R. P.; Amado, R. D. 5549

Solution of a singular integral equation from scattering theory.

J. Mathematical Phys. **5** (1964), 1340–1342.

In the field-theoretical model originally proposed by T. D. Lee [Phys. Rev. (2) **95** (1954), 1329–1334; MR **16**, 317] and later studied by many authors, one encounters a singular integral equation describing the scattering of the "V-particles" by the "θ-particles" [the reviewer and W. Pauli, Danske Vid. Selsk. Mat.-Fys. Medd. **30** (1955), no. 7; MR **17**, 927]. So far, the explicit solution of this integral equation has not been known completely. A few years ago one of the present authors [R. D. Amado, Phys. Rev. (2) **122** (1961), 696–704; MR **25** #2827] succeeded in extracting the energy shell contribution to the scattering matrix by using dispersion-theoretic methods. Evidently, such an approach cannot be immediately generalised to off-shell quantities like the complete scattering amplitude. In the present paper, the authors find a particular solution of the scattering equation in question. This solution is found by heuristic arguments and is afterwards verified by direct substitution to be a solution of the equation in question. Consequently, the authors have found also the off-shell scattering amplitude in the $V-\theta$ sector.

The authors do not claim that their solution is the most general solution of the integral equation under investigation. However, they state (and the reviewer agrees) that their solution most probably is the unique solution which is of physical importance to describe $V-\theta$ scattering in the Lee model. Finally, it should be mentioned that a very similar result has been obtained independently by A. Pagnamenta [Bull. Amer. Phys. Soc. **9** (1964), 449, FE5]. *G. Källén* (Lund)

Lurçat, F.; Mazur, P. 5550

Statistical mechanical evaluation of phase-space integrals. (Italian summary)

Nuovo Cimento (10) **31** (1964), 140–153.

It is observed that the computation of phase-space integrals for many-particle processes, with conservation of total energy, is related to the evaluation of microcanonical partition functions in statistical mechanics. In the latter case, extension to a canonical ensemble simplifies the integrals, and it is shown that the same is true in the former. Some numerical examples are given. *H. W. Lewis* (Madison, Wis.)

Malik, F. B. 5551

On the variational method for nonrelativistic scattering. I. Differential form.

Ann. Physics **20** (1962), 464–478.

Two alternative variational procedures for the solution of scattering problems using the differential form of the Schrödinger equation are examined, one due to Hulthén [Kungl. Fysiogr. Sällsk. i Lund Förhandl. **14** (1944), no. 8; MR **6**, 110; Ark. Mat. Astronom. Fys. **35A** (1948), no. 25; MR **10**, 120], the other due to Kohn [Phys. Rev. (2) **74** (1948), 1763–1772]. The criticism made by Schwartz [Ann. Physics **16** (1961), 36–50; MR **24** #B269], that the trial parameters do not vary smoothly with energy, but become infinite at certain energies, is reviewed and another question is raised: How can there be two different variational procedures using the same functional? The author shows that both of these difficulties are connected with a more fundamental problem. Hulthén's, as well as Kohn's, equations for the former's functional are not enough to satisfy the Euler equation of the variational problem because the phase shift found in either way usually fails to reflect the asymptotic behavior of the wave functions. The author suggests a set of variational equations to replace the usual self-consistency procedure. This insures that the Schrödinger equation becomes the Euler equation of the variational problem. With this modification, Hulthén's and Kohn's methods become equivalent, and choices of trial wave functions giving rise to discontinuous parameters are automatically excluded. Finally, the author points out that in all those cases already calculated, where Hulthén's or Kohn's method gave good results, his prescription has, in fact, been applied. *H. Lustig* (New York)

Malik, F. B. 5552

On the variational method of the nonrelativistic scattering. II. The integral form.

Ann. Physics **21** (1963), 1–7.

As in his discussion of the differential form of the variational approach to scattering problems [see #5551 above], the author is here concerned with making the variational equations consistent with the boundary conditions at large distances. An appropriate modification to insure this consistency is introduced in the integral variational procedure of Schwinger [Mimeographed lecture notes, Vol. II, Harvard, 1947; see also Blatt and Jackson, Phys. Rev. (2) **76** (1949), 18–37]. As a second approach, the author develops an expression for the variational functional which corresponds to the integral form of the functional used in the differential procedure. This

second type of functional looks somewhat simpler than Schwinger's, and since the presence of a Green's function makes the application of the integral version difficult at times, this may be an advantage. *H. Lustig* (New York)

Martin, J. L. 5553

Covariant quantum field theories with indefinite metric, and the Lorentz covariant Lee model.

Proc. Roy. Soc. Ser. A **272** (1963), 231–240.

This is an important paper and describes an attempt at the construction of a covariant finite quantum field theory of relativistic particle interactions. The author introduces creation and destruction operators for particles with both positive and negative energies. For spin zero particles a natural scalar product may be defined which associates positive [negative] definite quadratic forms with positive [negative] frequency amplitudes for a single particle. A Lorentz-invariant version of the Lee model that was considered before by the author [same Proc. **271** (1963), 332–356; MR **26** #5874] can be given an operator formulation, and this is carried out here. This paper raises the important question: Is it possible to construct a complete relativistic field theory with non-trivial crossing symmetry and no explicit infinities?

Weaver, D. L.; Hammer, C. L.; Good, R. H., Jr. 5554

Description of a particle with arbitrary mass and spin.

Phys. Rev. (2) **135** (1964), B241–B248.

Authors' summary: "A Lorentz covariant description of a particle and antiparticle with spin $s=0, \frac{1}{2}, 1, \cdots$ and finite rest mass is given in this paper. The wave function has $2(2s+1)$ components so that no auxiliary conditions are needed. The basic idea is to postulate the rest-system Hamiltonian and make the Lorentz transformation to the laboratory system. An algorithm which is a generalization of the Foldy-Wouthuysen transformation is found for constructing the laboratory-system Hamiltonian and polarization operators." *C. G. Bollini* (Buenos Aires)

An extension of Feynman-Bunge-Corben's relation regarding the position-operator of Dirac electron to arbitrary operators. II.

Progr. Theoret. Phys. **31** (1964), 324–325.

The physical meaning of certain operators $\tilde{Q}$ [see #5555 above] is discussed. This letter and the one reviewed above summarize the work reported in Soryusiron Kenkyu **16** (1957), 351; ibid. **27** (1963), 540. *F. Calogero* (Rome)

Grashin, A. F. [Grašin, A. F.] 5557

Solution of the linear equations of the dispersion method in the two-particle approximation.

Ž. Èksper. Teoret. Fiz. **43** (1962), 277–286 (*Russian. English summary*); *translated as Soviet Physics JETP* **16** (1963), 198–204.

A solution of the linear equation

$$F(t) = \tilde{F}(t)+\frac{t^N}{\pi}\int_{4\mu^2}^{\infty}\frac{\operatorname{Im} F(t')\,dt'}{(t'-t)t'^N},$$

$$\operatorname{Im} F(t) = F(t)e^{-i\delta(t)}\sin\delta(t)+f(t), \quad f(t) = 0 \text{ for } t < 16\mu^2,$$

is sought, which requires stability (for $t<T\approx 16\mu^2$) against perturbations of $f(t)$ at infinity. The solution $F(t)$, calculated in the vicinity of $|t|\leq T$ with an accuracy $\sim|t/T|$, is unique and has the form

$$F(t) = \tilde{F}(t)+\varphi(t)\frac{t^N}{\pi}\int_{4\mu^2}^{\infty}\frac{\tilde{F}(t)\exp\{i\Delta\}\sin\Delta}{(t'-t)t'^N\varphi(t')}\,dt',$$

$$\varphi(t) = \exp\left\{\frac{t-t_0}{\pi}\int_{4\mu^2}^{\infty}\frac{\Delta(t')\,dt'}{(t'-t-i0)(t'-t_0)}\right\},$$

where the auxiliary phase $\Delta(t)$ has a simple, integrable form, which approximates the input phase $\delta(t)$ with an accuracy $\sim t/T$ for $|t|<T$. *S. Ciulli* (Bucharest)

Morey, F. [Morey Terry, F.] 5558

Definition of nuclear potentials from double dispersion relations in field theory and potential scattering. (Italian summary)

Nuovo Cimento (10) **24** (1962), 585–605.

Charap and Fubini [Nuovo Cimento (10) **14** (1959), 540–559; MR **22** #6478] have shown that one may define a potential for the scattering of bosons interacting through a charged pseudo-scalar meson, consistent with the results of the field theory. In the present note these results are generalized to take into account the fermionic nature of the nucleons. In order to reproduce the field theory results, five direct and five exchange potentials are introduced. Finally, a method for the explicit calculation of the potentials is given. *S. Ciulli* (Bucharest)

Parasjuk, O. S. 5559

Feynman integrals and the method of Poincaré. (Russian)

Ukrain. Mat. Ž. **15** (1963), 320–321.

Recently the analyticity properties of Feynman amplitudes as functions of invariants have been studied extensively. For a survey of this work, see, for example, J. C. Polkinghorne [*Lectures in theoretical physics*, Vol. 1, pp. 102–167, Benjamin, New York, 1962; MR **27** #2290]. The author points out that the methods used were already employed by Poincaré in the perturbation theory of celestial mechanics. Both Poincaré and modern authors base their technique on deformation of contours of integration and the concepts of coinciding singularities and pinching of contours. (Poincaré even used the English word "pinch" at one point.) The works cited by the author are the following. [H. Poincaré, Bull. Astronom. **14** (1897), 353–354; reprinted in *Œuvres de Henri Poincaré*, Tome VIII, pp. 110–111, Gauthier-Villars, Paris, 1952; MR **15**, 277; Bull. Astronom. **15** (1898), 449–464; reprinted in

Œuvres de Henri Poincaré, Tome VIII, pp. 33–47, Gauthier-Villars, Paris, 1952; MR 15, 277; *Les méthodes nouvelles de la mécanique céleste*, Vol. I, Gauthier-Villars, Paris, 1892.] *R. L. Warnock* (Chicago, Ill.)

Parasjuk, O. S. 5560

Dual dispersion relations. (Russian)

Ukrain. Mat. Ž. **13** (1961), *no.* 3, 100–103.

Nakanishi [Progr. Theoret. Phys. **25** (1961), 155] showed that the sufficient and necessary condition that a function $M(s, t)$ defined by

$$M(s,t) = \int_0^1 dz \int_0^\infty d\alpha \frac{\Psi(z,\alpha)}{\alpha - zs - (1-z)t - i\epsilon}$$

satisfies the Mandelstam representation $M(s, t) = \int_0^\infty ds' \int_0^\infty dt' \varphi(s', t')/(s'-s-i\varepsilon)(t'-t-i\epsilon)$ is

$$\Psi(z,\alpha) = \int_0^\infty ds' \int_0^\infty dt' \varphi(s',t')\delta'(\alpha - zs' - (1-z)t').$$

For

$$\Psi(z,\alpha) = \frac{\delta(\alpha - (1-z)m_2{}^2 - zm_1{}^2)}{(1-z)m_2{}^2 + zm_1{}^2 - z(1-z)M^2}$$

the Nakanishi condition is fulfilled only if $|m_1 - m_2| < M < m_1 + m_2$.

The author gives a very short proof of the above result by investigating Nakanishi's condition with the help of a Fourier transform. His Fourier method seems to provide a general powerful tool in the investigation of similar problems. *S. Ciulli* (Bucharest)

Parasyuk, O. S. [**Parasjuk, O. S.**] 5561

A generalization of a theorem of T. Regge.

Dokl. Akad. Nauk SSSR **147** (1962), 571–572 (*Russian*); *translated as Soviet Physics Dokl.* 7 (1963), 976–977.

The author discusses the connection between a result of the reviewer [Nuovo Cimento (10) **14** (1959), 951–976; MR **26** #1088] on expansion in Legendre polynomials, a theorem of Le Roi-Lindelöf [E. Lindelöf, *Le calcul des résidus et ses applications à la théorie des fonctions*, Gauthier-Villars, Paris, 1905], and Faber's theorem [O. S. Parasjuk, Dokl. Akad. Nauk SSSR **145** (1962), 1247–1248; MR **26** #7350]. The possibility of extending the reviewer's result is also discussed. *T. Regge* (Turin)

Mestvirišvili, M. A.; Teplickiĭ, È. S. 5562

Quasi-stationary levels in a cylindrical magnetic field. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **35** (1964), 293–298.

An application of the Regge-pole method [T. Regge, Nuovo Cimento (10) **14** (1959), 951–976; MR **26** #1088] to a problem with cylindrical symmetry is presented. The problem discussed is that of quantum-mechanical scattering by a homogeneous magnetic field restricted to the interior of the infinite cylinder. The Sommerfeld-Watson transformation on the S-matrix is performed, and Regge trajectories in some special cases are found.

Klotz, A. H. 5563

On the mathematical foundations of relativistic quantum mechanics of particles with variable mass. (Italian summary)

Nuovo Cimento (10) **32** (1964), 1191–1201.

Author's summary: "The mathematical formulation of the relativistic quantum theory of particles with variable mass is discussed. Some difficulties arising from it are removed and it is pointed out that there exists a generalization within the framework of its assumptions. The transformation properties of the space of the new spin operators η are considered. It is shown that the second-order wave equation of the theory necessarily involves terms linear in the displacement operators. A suggestion is made concerning an introduction of the isobaric spin space into the theory."

Królikowski, W. 5564

Remarks on SU_3 triplets.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 339–341.

The author amends his previous SU(4) idea [Nuclear Phys. **52** (1964), 342–344; MR **28** #5748] by introducing hypothetical baryon SU(3) triplets instead of the suggested leptons. This then becomes identical with the theory previously put forward by P. Tarjanne and V. L. Teplitz [Phys. Rev. Lett. **11** (1963), 447–448].

Y. Ne'eman (Pasadena, Calif.)

Kurşunoğlu, Behram; Perlmutter, Arnold (Editors) 5565

★**Coral Gables Conference on Symmetry Principles at High Energy.**

January 30–31, 1964, University of Miami.

W. H. Freeman and Co., San Francisco, Calif.-London, 1964. viii + 171 *pp.* $4.75.

The publisher and the editors have to be strongly praised for bringing out these conference proceedings in a relatively short time and in a very satisfactory format. The first of the editors also added a further touch of his personality by procuring on the cover an amusing picture of Nasreddin Hoja sitting on his donkey and adorned with symbols of elementary particles.

Symmetry principles in leptonic weak interactions are discussed by R. Marshak. A possible merger of SU_3 and the Lorentz group is proposed by B. Kurşunoğlu. The first experiments to find quarks are reviewed by R. Adair. Departures from the eightfold way are discussed by S. Glashow. L. Biedenharn analyzes operator structures in SU_3 with an application to triplets. Certain aspects of Cabibbo's suggestion for SU_3 symmetry in weak interactions are commented on by P. Matthews. The possibility of the existence of an exact higher symmetry encompassing both internal and space time symmetry is proposed in the contribution by A. Barut. Y. Ne'eman reports on interesting speculations concerning the origin of internal symmetries in the light of some cosmological possibilities. Experimental consequences of SU_3 are analyzed by S. Meshkov. J. Schwinger proposes the W_3 symmetry and the field theory based on it. In the closing talk Ne'eman presents a thorough review of the then-current status of internal symmetries. *P. Roman* (Boston, Mass.

On collective perturbations of certain magnetic states. (Russian. Armenian summary)
Akad. Nauk Armjan. SSR Dokl. **39** (1964), 73–79.
The variational method of Bogoljubov [N. N. Bogoljubov, Uspehi Fiz. Nauk **67** (1959), 549–580; MR **22** #1395] is applied to a model of magnetic material in order to find the spectrum of the elementary excitations above the ground state. Because only normal and not superconducting states occur, the equations are rather simpler than in the original applications of the method. The author shows that there are two types of ferromagnetic states, one corresponding to transverse and the other to longitudinal spin waves, and in each case there is both a continuous and a discrete branch of the spectrum. The case of Overhauser spiral spin waves is also considered.

Kraichnan, Robert H. 5568
Stochastic models for many-body systems. I. Infinite systems in thermal equilibrium.
J. Mathematical Phys. **3** (1962), 475–495.
Author's summary: "Some model Hamiltonians are proposed for quantum-mechanical many-body systems with pair forces. In the case of an infinite system in thermal equilibrium, they lead to temperature-domain propagator expansions which are expressible by closed, formally exact equations. The expansions are identical with infinite subclasses of terms from the propagator expansion for the true many-body problem. The two principal models introduced correspond, respectively, to ring and ladder summations from the true propagator expansion, but augmented by infinite classes of self-energy corrections. The latter are expected to yield damping of single-particle excitations. The eigenvalues of the ring and ladder model Hamiltonians are real, and they are bounded from below if the pair potential obeys certain conditions. The models are formulated for fermions, bosons, and distinguishable particles. In addition to the ring and ladder models, two simpler types are discussed, one of which yields the Hartree-Fock approximation to the true problem. A novel feature of all the model Hamiltonians (except the Hartree-Fock) is that they contain an infinite number of parameters whose phases are fixed by random choices. Explicit closed expressions are obtained for the Helmholtz free energy of all the models in the classical limit."

Kraichnan, Robert H. 5569
Stochastic models for many-body systems. II. Finite systems and statistical nonequilibrium.
J. Mathematical Phys. **3** (1962), 496–521.
Author's summary: "In a preceding paper [#5568], some model Hamiltonians were proposed for quantum-mechanical many-body systems with pair forces. For infinite systems in thermal equilibrium, they led to temperature-domain propagator expansions which were formally summable and expressible by closed equations. These expansions were identical with infinite subclasses of terms from the propagator expansion for the true many-body problem. The two principal models corresponded to ring- and ladder-diagram summations from the true propagator expansion, augmented by infinite classes of self-energy corrections. The model Hamiltonians were called stochastic because they contained parameters whose phases were fixed by random choices. In the present paper, more general models are formulated which yield formally summable propagator expansions for finite systems. The analysis is extended to correlation and Green's functions defined for nonequilibrium ensembles. The nonequilibrium treatment is developed in the Heisenberg representation in such a way that unlinked diagrams do not arise. A basic convergence question associated with the formal closed equations for the model propagators and correlation functions is examined by means of finite-difference integration of the Heisenberg equations of motion. This procedure appears to converge independently of whether the perturbation expansions for the propagators and correlation functions converge. It yields substantial support for the validity of the formal closed model equations."

★Order-disorder phenomena.
Monographs in Statistical Physics and Thermodynamics, Vol. 5.
Interscience Publishers [John Wiley & Sons, Ltd.], London-New York-Sydney, 1964. x + 363 *pp.* $15.00.
About two-thirds of this book is devoted to a detailed review of the Ising problem. The other third is a general discussion of the theory of order-disorder phenomena but apparently with the main object of showing that the Ising problem is the key to the understanding of nearly all order-disorder transitions. This general discussion gives only a very brief account of experimental results or approximate calculations but enough background so that a mathematician with limited knowledge of physics will learn why the Ising problem has attracted so much attention. The review of the Ising problem describes the recent method developed by the authors for evaluation of the partition function for various two-dimensional Ising lattices from the properties of Pfaffians, as well as the older algebraic and combinatorial methods. Exact evaluations of correlations and magnetization are also reviewed.

The book naturally concludes with a chapter on the unsolved problems for the next generation of Ising enthusiasts. It is an excellent introduction for the ambitious young mathematician who hopes he will be the first to solve the three-dimensional Ising problem or even for the less ambitious ones who only wish to know what the others dream about.

★Électrodynamique des plasmas fondée sur la mécanique statistique. Tome I: Processus physiques et méthodes mathématiques.

Cours professé à la Sorbonne en troisième cycle.

Dunod, Paris, 1963. xx + 622 *pp.*

The renewal of interest in the physics of ionised gases, brought about by the stimulus of the attempt to achieve a controlled thermonuclear reaction and by developments in space physics, has led to a steadily increasing output of books on the subject, ranging from the introductory to monographs on special topics. The present book differs from most of the others in that the authors have adopted what might be called the encyclopaedic approach. Perhaps the strongest argument in favour of this is that, at best, it allows a uniform and comprehensive treatment of a very wide field; the pitfalls inherent in such an approach are apparent.

Volume I of the Electrodynamics of Plasmas deals with physical processes and mathematical methods, and runs to just over 600 pages in doing so (a list of topics to be included in the second volume suggests that it will not be less lengthy). While one understands such a work being bulky, one inevitably asks if it need run to as many pages as it does. In this case the reviewer feels that the answer must be "no", and the reason is to be found, in the first instance, in Chapter 1 which discusses the general properties of plasmas and fundamental atomic processes. No doubt it is proper to introduce and define the basic lengths and frequencies (Debye length, plasma frequency, etc.), although one might question to what extent this is necessary in a book unlikely to be used by complete beginners; what does not seem proper to this reviewer is to include a discussion of atomic collision phenomena, in itself a subject with a vast literature. The twenty-odd pages taken up in this way amount to nothing more than an incomplete catalogue of collision processes which could well have been left out.

Chapter 2 deals with the principles of statistical mechanics, while Chapters 3 and 4 are devoted to the motion of individual particles. Chapters 5–8 contain the main part of the work, the discussion of the Boltzmann equation, in this the treatment is fairly standard. Chapter 6, which devotes some 100 pages to general methods of handling the Boltzmann equation, is perhaps the most successful in the book; more recent developments in kinetic theory due to Grad, Ikenberry and Truesdell, amongst others, are touched on and the bulk of the chapter is taken up with the classical Chapman-Enskog theory. Other subjects which are mentioned rather than treated include the Vlasov equation and the phenomenological collision term of Bhatnagar, Gross and Krook. Unfortunately, the book does not end with the final chapter. There follow some 100 pages of appendices and one cannot avoid asking why, in this age, and in a book at this level, the authors feel obliged to take space to define vector operators grad and div, and to discuss Legendre functions, Hermite and Laguerre polynomials. The book ends with a short bibliography and an adequate index.

In attempting this difficult task the authors, in the first part of their work, have been something less than successful. It remains to say that the print is clear and the book attractively produced.

T. J. M. Boyd (Culham)

Ekstein, H. 5572

Time reversal and superselection. (Italian summary)

Nuovo Cimento (10) 23 (1962), 606–615.

Author's summary: "The physical requirements on the time-reversal operator are reformulated in terms of observables and proper states. These requirements entail superselection rules which are consistent with experiment."

Rau, Jayaseetha 5573

Relaxation phenomena in spin and harmonic oscillator systems.

Phys. Rev. (2) 129 (1963), 1880–1888.

Author's summary: "A method is developed for generating relaxation by introducing a fundamental interval τ and a stirring hypothesis. The application to spin and harmonic oscillator systems is discussed in some detail. All the results are obtained by exact calculations without applying perturbation theory, as the systems considered are simple and completely soluble. Equations similar to phenomenological Bloch equations are derived in the case of spin systems. The relaxation times obtained by the application of the theory are not only proportional to the strength of interaction, but also to the fundamental interval τ which plays an important role in the theory. It is shown that in the case of a harmonic oscillator system, an initial Boltzmann distribution relaxes to a final equilibrium Boltzmann distribution through a sequence of transient Boltzmann distributions."

Stephenson, John 5574

Ising-model spin correlations on the triangular lattice.

J. Mathematical Phys. 5 (1964), 1009–1024.

Author's summary: "A Pfaffian representation of the partition function of the triangular lattice is used to derive expressions for various two, four, and six spin correlations in terms of Pfaffians. The pair correlations along a diagonal are expressed as a Toeplitz determinant whose limiting form yields the spontaneous magnetization. At the ferromagnetic critical point the correlations decay as $1/r^{1/4}$ with approximately radial symmetry. At the antiferromagnetic zero point the ground state is highly degenerate—it has finite entropy—and on a given sublattice the pair correlations along a row decay as $\varepsilon/r^{1/2}$, where $\varepsilon = +\varepsilon_0$ on the sublattice containing the origin spin and $\varepsilon \simeq -\frac{1}{2}\varepsilon_0$ on the other two sublattices. Finally, the perpendicular susceptibility, $\chi_\perp$, which depends on a finite number of correlations, is calculated; its ferromagnetic behavior is similar to that of the perpendicular susceptibilities of the quadratic and honeycomb lattices, but for an antiferromagnet $\chi_\perp$ diverges as $1/T$ at low temperatures."

G. Newell (Providence, R.I.)

Newman, David S. 5575

Equation of state for a gas with a weak, long-range positive potential.

J. Mathematical Phys. 5 (1964), 1153–1157.

Author's summary: "A one-dimensional fluid model in which the pair interaction potential is exponential and repulsive is considered, and the equation of state in the 'long-range' limit is determined exactly. This model is complementary to one studied by Kac, in which the pair

potential consists of a hard core and an exponential, attractive tail. In that model a phase transition occurs, but in the current model there is no phase transition. This fact lends support to a conjecture of Ruelle that no phase transition occurs if the potential is bounded. The possibility of applying the method of Kac to a wider class of potentials is suggested, and some of the mathematical difficulties yet to be overcome are outlined."

N. L. Balazs (Stony Brook, N.Y.)

Oser, Hansjörg; Shuler, Kurt E.; Weiss, George H. 5576

Relaxation of a Lorentz gas with a repulsive r^{-s} force law.

J. Chem. Phys. 41 (1964), 2661–2666.

Authors' summary: "The relaxation of a Lorentz gas (dilute light particle subsystem in a heavy particle heat bath) has been studied for a repulsive r^{-s} central force law interaction between the light and heavy particles. The Fokker-Planck equation for the velocity distribution functions of the light particle subsystem has been solved numerically for $s=5$, 9, 13, 21, and ∞ for various initial conditions. The dependence of the rate of relaxation and of the form of the time-dependent velocity distribution function on the force law parameter s is discussed in light of the above results."

A useful and interesting collection of problems and answers, with attention paid to numerical aspects.

Chu, C. K. 5578

Dynamics of ionizing shock waves: Shocks in transverse magnetic fields.

Phys. Fluids 7 (1964), 1349–1357.

Shock waves propagate through a non-ionized neutral gas and ionize it into a perfect conducting gas. The magnetic field is transverse. With the additional assumption of no ionization energy, it is found that the direction of the magnetic field is unchanged in both sides of the shock waves and that the imposed electric field ahead of the shock may not be arbitrarily imposed, but is determined by the shock structure. Then the piston problem is solved for these shocks. It is found that for a given ionization temperature these shocks are pure gasdynamic shocks at low piston speeds and approach classical hydromagnetic perpendicular shocks at high piston speeds.

L. N. Tao (Chicago, Ill.)

Guernsey, Ralph L. 5579

Kinetic equation for a completely ionized gas.

Phys. Fluids 5 (1962), 322–328.

This paper considers the problem of the time development of the velocity distribution function for a gas of particles with Coulomb interactions. The assumptions made are: (1) only the first two equations of the BBGKY hierarchy need to be considered, and (2) the deviations from thermal equilibrium are small and linear ratios of the equations are permissible. No assumption is made, however, that the time scale of relaxation of the two-particle function is short compared to the kinetic time scale governing the change of the one-particle functions. A complicated set of coupled integro-differential equations results, which are solved formally by a technique utilizing the theory of singular integral equations. *A. Lenard* (Princeton, N.J.)

Guernsey, Ralph L. 5580

Kinetic theory of the classical electron gas in a positive background. I. Equilibrium theory.

Phys. Fluids 7 (1964), 792–802.

An approximate method for calculating equilibrium properties of systems where the interaction consists of two parts, short range and weak interaction, is developed. By introducing formal parameters into the BBGKY hierarchy, a new set of equations is obtained which can be solved recursively. The solutions are then continued analytically in these parameters to obtain approximate solutions to the BBGKY hierarchy. The equation of state for an electron gas which is found agrees through second order in the plasma parameter with previous calculations by diagrammatic methods. *J. K. Thurber* (New York)

Macke, W.; Pegel, B. 5581

Anonyme Beschreibung und hydrodynamische Näherung für ein klassisches Plasma.

Ann. Physik (7) 12 (1963/64), 398–408.

The authors show that a description of a many-body system (e.g., a plasma) can be made in terms of the microscopic mass-density $\mu(\mathbf{r})=\sum_i m_i\delta(\mathbf{r}-\mathbf{r}_i)$ and a canonically conjugate field $\Phi(\mathbf{r})$. They show that a canonical transformation can be found, leading from the usual positions and momenta $\mathbf{r}_i$, $\mathbf{p}_i$ to the continuous canonical variables $\mu(\mathbf{r})$ and $\Phi(\mathbf{r})$. It is also shown that $\Phi(\mathbf{r})$ has the simple physical meaning of a velocity potential, such that $\mathbf{v}(\mathbf{r})=\operatorname{grad}\Phi(\mathbf{r})$. The canonical equations of motion are derived, and from these, by suitable averaging, a system of hydrodynamical equations is obtained. Whereas this first part is very elegant, the approximations necessary in order to close the hierarchy of hydrodynamical equations are less transparent in the reviewer's opinion.

R. Balescu (Brussels)

McCune, James E. 5582

Master equation for plasmas.

Phys. Fluids 7 (1964), 1306–1320.

Author's summary: "A straightforward derivation of the general kinetic equation describing the irreversible evolution of the N-momenta distribution function for a classical spatially homogeneous stable plasma ($nr_D^3>1$) is given. Collective effects are included. This plasma master equation reduces to the weak-coupling master equation when collective effects are neglected. The results are given first in terms of a coupled pair of equations analogous to those obtained by Bogoliubov for the kinetic description of a plasma. The equation for the generalized correlations is then solved for stable plasmas in terms of the N-momenta distribution function; the master equation then follows by substitution, and is shown to possess an H-theorem. The conditions under which these results

reduce to the kinetic equation of Balescu and Lenard are discussed. The origins of irreversibility in plasmas are discussed in the light of this and other recent work, and the properties of the stationary solutions of the general kinetic equations are analyzed." *R. Balescu* (Brussels)

Mermin, N. David; Canel, Eric 5583

Long wavelength oscillations of a quantum plasma in a uniform magnetic field.

Ann. Physics **26** (1964), 247–273.

An interesting discussion of the longitudinal plasma oscillation of an electron gas in a uniform magnetic field is given. The Coulomb interaction between the electron is treated in the random phase approximation. Most of the results are for the case of the degenerate gas and are thus of interest in metals. The spectrum of plasma oscillation in the presence of the field shows interesting resonances at the Larmor frequency and higher integral multiples of this frequency. Some of these effects may be observable in the spectrum of metals or semiconductors.

M. J. Stephen (New Haven, Conn.)

Minardi, E. 5584

Energy principle for electrostatic stability of a plasma.

Nuovo Cimento (10) **31** (1964), 674–678.

Engelmann, Feix, and the author [Nuovo Cimento (10) **30** (1963), 830–836] have formulated the equilibrium conditions for a non-uniform one-dimensional collisionless plasma in zero magnetic field. In the present paper their result is re-formulated as a variational principle. For a stable plasma the variational principle is to minimize the electrostatic energy subject to a certain constraint. On the other hand, if the electrostatic energy is maximum, then the plasma is unstable. *O. Penrose* (London)

Ron, Amiram 5585

Scattering of electromagnetic waves by an electron-phonon system.

Phys. Rev. (2) **132** (1963), 978–985.

A theory is developed to describe the scattering of electromagnetic waves by the electron density fluctuations in an electron-phonon system. Most attention is directed to frequencies of the electromagnetic radiation in the neighborhood of the plasma frequency. At these energies the total amount of scattered radiation is very small and the shifts due to the phonon resonances are small but may be observable with sensitive detectors.

M. J. Stephen (New Haven, Conn.)

Velibekov, É. R. [Velibekov, È. R.] 5586

A generalized self-consistent field method and collective excitations in the superconductivity theory.

Dokl. Akad. Nauk SSSR **150** (1963), 1015–1018 (*Russian*); *translated as Soviet Physics Dokl.* **8** (1963), 576–579.

The longitudinal collective excitations of a superconductor are investigated when the attractive pair interaction takes place in higher angular momentum states than the s state. The collection excitations have the same angular momentum as the attractive interaction. If the Coulomb interaction is taken into account, these longitudinal waves become ordinary plasma waves as in the case of an s state interaction. *M. J. Stephen* (New Haven, Conn.)

Levine, Arnold D. 5587

Lagrangian formulation of the phonon field equations.

J. Mathematical Phys. **5** (1964), 1615–1618.

An action principle is given for one space variable, x, and one time variable, t, which yields the equations of lattice vibrations as equations of motion. These are differential equations with respect to t, but difference equations with respect to x. The theory is therefore non-local in x. The resulting conservation laws of energy and momentum are also difference equations with respect to x. The boundary conditions are necessarily specified over one lattice spacing. The theory is then quantized in the canonical fashion. The commutator becomes a sum of periodically spaced delta-function singularities. The generalization to the three-dimensional case is discussed.

On the theory of classical fluids. III.

Physica **30** (1964), 95–104.

Part II (by the author and Levesque) appeared in Physica **28** (1962), 1124–1142 [MR **29** #830]. The author considers one way of systematically improving the Percus-Yevick (PY) and hypernetted chain (HNC) approximations to the pair distribution function of a classical fluid. Percus has shown how to obtain each of these approximations by truncating an appropriate functional Taylor expansion [Phys. Rev. Lett. 8 (1962), 462–463]. The author investigates the equations that result from retaining one more term in both of these expansions. In each case a second equation must be introduced to determine the approximate distribution function. The author obtains his second equation by introducing another functional equation. He assesses the accuracy of the resulting approximations by applying them to a system of hard cubes (in one, two, and three dimensions) and comparing the resulting fourth and fifth virial coefficients with the known exact coefficients for this system. (The author has subsequently [preprint] investigated a somewhat different second equation for each approximation and has also corrected an error in his tabulation of the fifth virial coefficient according to the improved HNC theory.) *G. Nodvik, John S. 5591

A covariant formulation of classical electrodynamics for charges of finite extension.

Ann. Physics 28 (1964), 225–319.

This is a detailed and careful treatment of Lorentz covariant charge distributions and their dynamics. It includes much of the previous work on this subject as special cases. The charge distributions are assumed to be rigid in the sense that they remain invariant for the inertial observer who is instantaneously comoving with the charge center; the latter point is also assumed to be the center of mass. The charge distribution is in general characterized by two invariant shape functions, one for translatory and one for relativistic rotatory motion. The latter motion is studied in detail, a subject not easily found elsewhere. The equations of motion are derived from a variational principle, and the conservation laws are given. Radiation reaction terms are computed in perturbation expansion. In this approximation gyromagnetic ratios are obtained for various distributions. The paper is restricted to sufficiently small accelerations, so that differential pair production does not occur. This means that an inertial observer will see no world line of an element of charge change its (time-like) tangent vector from the future to the past light cone. *F. Rohrlich* (Syracuse, N.Y.)

DeWitt, C.; DeWitt, B. (Editors) 5592

★Relativité, groupes et topologie [Relativity, groups and topology].

Lectures delivered at Les Houches during the 1963 session of the Summer School of Theoretical Physics, University of Grenoble.

Gordon and Breach, Science Publishers, New York-London, 1964. xvi + 929 *pp*. $19.50.

This book is a collection of many outstanding contributions, mostly pedagogic in nature, which will be of great use, not only to students of general relativity and gravitation, but also to people interested in elementary particle theory. The authors and the editors, as well as the publisher, cooperated magnificently in producing from the lectures a real book which does not carry at all the characteristics of lecture notes.

The contents of this collection are as follows: (I) J. L. Synge, "Introduction to General Relativity"; (II) F. Gürsey, "Introduction to Group Theory"; (III) R. H. Dicke, "Experimental Relativity"; (IV) J. A. Wheeler, "Geometrodynamics and the Issue of the Final State"; (V) R. K. Sachs, "Gravitational Radiation"; (VI) R. Penrose, "Conformal Treatment of Infinity"; (VII) B. S. DeWitt, "Dynamical Theory of Groups and Fields"; (VIII) A. Lichnerowicz, "Propagateurs, Commutateurs et Anticommutateurs en Relativité Générale"; (IX) J. Weber, "Gravitational Radiation Experiments"; (X) C. W. Misner, "Differential Geometry and Differential Topology".

These papers will be reviewed individually.

P. Roman (Boston, Mass.)

Synge, J. L. 5593

Introduction to general relativity.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp*. 1–88. *Gordon and Breach, New York*, 1964.

This is a condensed, very readable introduction to classical general relativity. Occasionally, attention is drawn to some subtleties which are often neglected in the current textbook literature. A large selection of exercises makes the text even more valuable for the student.

P. Roman (Boston, Mass.)

Gürsey, Feza 5594

Introduction to group theory.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp*. 89–161. *Gordon and Breach, New York*, 1964.

This article serves as a good, but somewhat too concise, introduction for students who will have to use group-theoretical methods in further work. Standard topics about abstract groups, representations, and Lie groups are covered in a very clear and pedagogic manner, and the survey ends with a more specific chapter on semi-simple groups which are connected with general relativity and elementary particle theory. *P. Roman* (Boston, Mass.)

Dicke, R. H. 5595

Experimental relativity.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp*. 163–313. *Gordon and Breach, New York*, 1964.

In these clearly written and very stimulating lectures, primary emphasis is given to null experiments. In this chapter the Eötvös experiment, the Dicke experiment, the experiments on the isotropy of space, and an interesting Princeton ether drift experiment are discussed. Next, the so-called fundamental tests of general relativity (red shift, deflection of light, perihelion rotation) are reviewed. Finally, some cosmic experiments are mentioned. The main text is followed by 12 reprints of previously published papers of the author (and co-workers), concerning mainly the possibility of an additional scalar field in the theory of gravitation and the exploring of its consequences. Generally, a somewhat wider framework than the conventional one is used in discussing the experiments, so as to show the limitations imposed by experimental findings on the possible theories.

P. Roman (Boston, Mass.)

Wheeler, John Archibald 5596

Geometrodynamics and the issue of the final state.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp*. 315–520. *Gordon and Breach, New York*, 1964.

The underlying motive of this long and rich treatise is the following: What is the reason, meaning, interpretation, and what are the implications of situations where a space-like 3-geometry, followed forward in time, develops an infinite curvature? Many examples of such phenomena are discussed in detail and are classified. Furthermore, preliminary considerations on the quantum level are offered which may show a way out of these difficulties. An interesting feature of the text is that it gives a large number of problems, some of them being exercises for the

student and some of them being yet unsolved, and even fundamental, questions.

The abbreviated table of contents is given below. (1) Introduction and Outline, The Falling Star; (2) The Nature of Dynamics; (3) The Variational Principle of General Relativity; (4) The "Thin-Sandwich" Variational Problem, The Initial Value Problem, and Mach's Principle; (5) The Expanding and Recontracting Universe: Is the Shift Unique?; (6) The Time Symmetric Initial Value Problem and Closure as an Eigenvalue Problem; (7) Time Symmetry and the Thin Sandwich; (8) Regge Calculus and Schwarzschild Geometry; (9) Schwarzschild Geometry, Space-Like Slices, and the Nature of Time; (10) The Reissner-Nordstrom Geometry: Again a Singularity after a Finite Proper Time; (11) The Topological Description of Electric Charge; (12) Universes Activated by the Longest Wave, and a New Type of Singularity; (13) Geons; (14) The Collapsing Cloud of Matter Reconsidered; (15) Gravitational Collapse and the Creation and Annihilation of Matter. *P. Roman* (Boston, Mass.)

Sachs, R. K. 5597a

Gravitational radiation.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp.* 521–562. *Gordon and Breach, New York*, 1964.

Penrose, Roger 5597b

Conformal treatment of infinity.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp.* 563–584. *Gordon and Breach, New York*, 1964.

The first paper discusses how the gravitational field equations determine the evolution of waves; then a geometrical analysis of the far field is given; finally, some comments are made on approximation methods.

In the second paper, the standard initial-value problem, the discussion of the geometry of a congruence of null-geodesics, and the characteristic initial-value problem are followed by an introduction to the Bondi-Metzner-Sachs group and a discussion of asymptotic symmetries. Then, after a section on the algebra of two-component spinors, the algebra of the Weyl tensor is presented, followed by the peeling theorem and comments on algebraically special fields. Finally, a brief discussion of the linearized theory is given. The article ends with a fine selection of problems for the student, some unsolved as yet. A substantial list of references is given.

P. Roman (Boston, Mass.)

DeWitt, Bryce S. 5598

Dynamical theory of groups and fields.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp.* 585–820. *Gordon and Breach, New York*, 1964.

The unusual title of this treatise is meant to indicate the development of a framework within which the quantization of fields possessing infinite-dimensional invariance groups may be carried out in a manifestly covariant fashion. In line with this purpose, an overall space-time view is adopted from the outset, and canonical formulations are ignored. The quantum outlook is stressed from the beginning, even though quite a lot is done at the classical level. The fundamental tool employed is that of functional derivatives. Concerning the notion of infinite-dimensional invariance groups, it is stressed that they lead primarily to identities on the dynamical equations, in contradistinction to the more familiar finite-dimensional groups, which lead to conservation laws whenever the dynamical equations are satisfied.

In order to gain a glimpse of the richness of this article, we believe the best approach is to quote the table of contents: (1) Fundamentals; (2) Small disturbances; (3) Invariance groups; (4) Measurement; (5) Measurement of two observables, The uncertainty principle, Commutators; (6) Green's functions; (7) Supplementary conditions, Cauchy data, Reciprocity relations; (8) Poisson-Jacobi identity, Invariance of the Poisson bracket, Canonical theory; (9) Asymptotic invariants; (10) Field quantization, Creation and annihilation operators, Positive-definiteness of Hilbert space, Electromagnetic and gravitational fields, Helicity; (11) Theory of continuous groups; (12) The Yang-Mills group; (13) The general coordinate transformation group; (14) Metric and spin; (15) Anticommuting fields; (16) Specific Lagrangians; (17) Bi-tensors, bi-spinors, and Green's functions; (18) Conservation laws; (19) The canonical transformation group, Time reversal; (20) The Schwinger variational principle; (21) The S-matrix; (22) The quantum action functional, The "tree" theorem; (23) External field problems, Lowest-order radiative corrections; (24) Renormalization.

This article is not for the beginner, and even for the one who is seasoned in field theory, it will prove to be difficult, but most rewarding, reading. By way of only criticism we may mention that the difficulties of comprehension are compounded by the fact that topics are often not given full discussion at the points where they are raised, but are completed only in several later sections.

P. Roman (Boston, Mass.)

Lichnerowicz, A. 5599

Propagateurs, commutateurs et anticommutateurs en relativité générale.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp.* 821–861. *Gordon and Breach, New York*, 1964.

This mathematically elegant and very valuable review article is divided into four major sections. First, the general mathematical theory of propagators is given, followed by a discussion of tensorial fields. Then, spinorial fields of various order are discussed, and finally, comments on creation-annihilation operators are made.

The whole discussion is restricted to free fields defined over a curved space-time manifold.

P. Roman (Boston, Mass.)

Weber, Joseph 5600

Gravitational radiation experiments.

Relativité, Groupes et Topologie (*Lectures, Les Houches, 1963 Summer School of Theoret. Phys., Univ. Grenoble*), *pp.* 863–880. *Gordon and Breach, New York*, 1964.

This article consists of two main parts. In the first part, the feasibility of gravitational radiation experiments is illuminated, together with a discussion of the possibility

of generating gravitational waves, and a brief description of current experiments at the University of Maryland. In the second part, using the Fock-Papapetrou method, equations of motion involving both gravitational and non-gravitational forces are deduced in the framework of general relativity. The purpose of this discussion is that the ensuing equations can be used to discuss means of measurement of the Riemann tensor.

P. Roman (Boston, Mass.)

Hlavatý, V.; Mishra, R. S. 5601

Classification of space-time curvature tensor: General theory of λ-classification.

Rend. Circ. Mat. Palermo (2) **11** (1962), 319–350.

Let V_4 be a (4-dimensional) Lorentzian manifold. A tensor on V_4 having the algebraic symmetry properties of the Riemann curvature tensor (but not its differential properties) is called a curvature tensor. Using the concepts and notation of another paper in press, the authors develop a classification of curvature tensors by Segre characteristics. They do not decompose the curvature tensors with respect to the Lorentz group (into Weyl, trace-free Ricci and scalar parts) before classification. More details are promised in a sequel.

F. A. E. Pirani (Waltham, Mass.)

Kühnel, Adolf 5602

Equations of motion in the theory of gravitational perturbations.

Ann. Physics **28** (1964), 116–133.

Following Fok [*Theory of space, time and gravitation* (Russian), GITTL, Moscow, 1955; MR **18**, 445] the author derives the equations of motion of a system of point particles as a suitable limit of the equations of motion of spherical drops of a perfect compressible fluid. The essential difference from Fok's work is the use of the "fast approximation" method [B. Bertotti and J. Plebański, Ann. Physics **11** (1960), 169–200; MR **22** #5440]. The task is formidable, and several equations require a whole page to be written.

In the first-order equations, the singular terms arising in the limit of zero size (and infinite density) are removed by a mass renormalization. Radiation "anti-damping' terms occur like those in electrodynamics, but with the opposite sign. In the second approximation, two subtractions are needed: one for the mass and one for the coupling constant. The radiative terms in the second-order equations are symmetric under time reversal. *A. Peres* (Haifa)

Misra, R. M. 5603

Geometry of the electromagnetic field. (Italian summary)

Nuovo Cimento (10) **32** (1964), 1561–1583.

The author discusses canonical forms of the curvature tensor $R_\mu{}^\nu$ in the presence of matter (μ), pressure (p) and an electromagnetic energy momentum tensor $F_\mu{}^\nu$, permissible under the assumption that the electromagnetic field is non-null. It is found that only certain multiplicities of the eigenvalues of $R_\mu{}^\nu$ are allowed under these conditions. In every case, the electromagnetic invariant F, matter density μ, and pressure p are expressed as concomitants of the curvature tensor.

A. H. Klotz (Liverpool)

Pichon, Guy 5604

Diffusion du rotationnel dans les fluides visqueux incompressibles.

C. R. Acad. Sci. Paris **259** (1964), 2363–2365.

The author points out that the equations for the rotation of an incompressible viscous fluid contain but first derivatives with respect to the time coordinate, and that to this extent we are dealing here with a Cauchy problem resembling that of the diffusion equation.

{Reviewer's comment: Both the diffusion equation and Helmholtz equations deal with quantities that (more or less) conserve, in one case the number of diffusing particles, in the other the angular momentum. Presumably, for some classes of fluids (those free of dissipative processes) the dynamics of the fluid obeys time-reversible laws, whereas an intrinsically dissipative process (such as diffusion) never does. The Cauchy problems in these circumstances must be fundamentally inequivalent.} *P. G. Bergmann* (New York)

Radhakrishna, L. 5605

Some exact non-static cylindrically symmetric electrovac universes.

Proc. Nat. Inst. Sci. India Part A **29** (1963), 588–595.

Author's summary: "The non-static cylindrically symmetric metric of L. Marder [Proc. Roy. Soc. London Ser. A **244** (1958), 524–537; MR **21** #1885] is considered, and some exact non-static solutions of the Einstein-Maxwell field equations in vacuo are obtained. These solutions include as particular cases uniform electromagnetic fields, which are transforms of Levi-Civita's homogeneous electric or magnetic fields [Atti Accad. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (5) **26** (1917), 1° semestre, 519–531]."

Caricato, Gaetano 5606

Principio dell'azione stazionaria e principio di Fermat in relatività generale.

Rend. Mat. e Appl. (5) **22** (1963), 416–426.

The author discusses Fermat-type variational principles governing the behavior of a test particle in a Riemannian manifold. *P. G. Bergmann* (New York)

Bonazzola, Silvano 5607

Un vecteur de Poynting pour la radiation gravitationnelle en relativité générale.

C. R. Acad. Sci. Paris **259** (1964), 1011–1014.

The author assumes that in a general coordinate system in space-time it is possible to associate with the metric tensor $g_{\mu\nu}$ another metric tensor, the metric tensor of a Minkowski space in the same coordinate system. In terms of these two tensors he defines a four-vector, the energy-momentum four-vector of the gravitational field whose divergence with respect to the first metric vanishes. He observes that his vector is not "gauge-invariant" and obtains the condition that infinitesimal coordinate transformations have to obey in order that the energy-momentum four-vector be invariant under such infinitesimal coordinate transformations.

A. H. Taub (Berkeley, Calif.)

Schmutzer, Ernst 5608

Einige Bemerkungen zur Theorie der Spinoren und Bispinoren in der gekrümmten Raum-Zeit. (Russian summary)

Acta Phys. Acad. Sci. Hungar. 17 (1964), 57–65.

Author's summary: "Das Postulat der Lorentzinvarianz der Diracschen Gleichung führt zu zwei Transformationsversionen: (1) Konstanz der Dirac-Matrizen und daher das wohlbekannte Transformationsgesetz für Spinoren; (2) Auffassung der Dirac-Matrizen als Tensoren und Interpretation der Wellenfunktion als einer Art von Invarianten. In der vorliegenden Arbeit wird die Sachlage für die gekrümmte Raum-Zeit untersucht. Zu diesem Zweck wird die Theorie der Spinoren und der Bispinoren in der gekrümmten Raum-Zeit kurz dargestellt."

The author re-concludes that version (2) cannot be generalized to curved space-time, making use of the Lie-Cartan integrability conditions. "Bispinoren" are what are often called 4-component spinors.

W. Rindler (Dallas, Tex.)

Schöpf, Hans-Georg 5609

Clebsch-Transformationen in der allgemeinen Relativitätstheorie. (Russian summary)

Acta Phys. Acad. Sci. Hungar. 17 (1964), 41–55.

The author derives Clebsch transformations for relativistic perfect fluids, and then generalizes his results to an electrically charged fluid interacting with an electromagnetic field. A variational principle for the general case is given. *W. Rindler* (Dallas, Tex.)

Staruszkiewicz, A. 5610

On propagation of the Riemann tensor in the theory of gravitation.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. 12 (1964), 271–273.

The author shows how to calculate, under the assumption of Einstein's field equations, all the components of the Riemann tensor and all its covariant derivatives on a spacelike hypersurface S ($x^0=0$) from the values of the metric and of the Christoffel symbols on S. From his formulae he deduces that if $R_{\lambda 0ik}$ $(i,k=1,2,3)$ vanishes on S, then $R_{\lambda\mu\nu\sigma}$ vanishes throughout space-time if it is real-variable analytic. It is then proved that $R_{\lambda 0ik}=0$ on S implies, without field equations, that S is embeddable in a four-dimensional Euclidean space.

W. Rindler (Dallas, Tex.)

Gregory, C. 5611

Search for extra-dimensional effects. (Italian summary)

Nuovo Cimento (10) **32** (1964), 1085–1091.

The author suggests that the presence of a fifth dimension, which is proposed in some unitary field theories [e.g., H. Weyl, Ann. Physik (4) **59** (1919), 101–133], might lead to extra statistical fluctuations, which could, for instance, become evident in Mössbauer effect experiments. A discussion of experimental data in the light of this conjecture is inconclusive.

{Reviewer's comments: The reference should have been to Kaluza [S.-B. Preuss. Akad. Wiss. **1921**, 966–972] and to projective theories (Veblen, Pauli, etc.) rather than to Weyl. Only some of these theories admit the fifth dimension as an additional degree of freedom, and the extent of the fluctuation associated with that degree of freedom is controlled.} *P. G. Bergmann* (New York)

Lal, K. B. 5612

Einstein's connections. III. Degenerate cases of the first class.

Proc. Nat. Inst. Sci. India Part A **29** (1963), 535–551.

This is substantially the summary of the author: In two recent papers [Lal and Mishra, Tensor (N.S.) **10** (1960), 218–237; MR **25** #1934; Proc. Nat. Acad. Sci. India Sect. A **32** (1962), 1–24; MR **28** #553], the solution of Einstein's first set of equations of the unified field theory has been studied in full detail in holonomic and non-holonomic forms for the degenerate cases $g=0$ and $a^2-4kb^2=0$ of the first class when $D\neq 0$, for the indices of inertia 0, 2 and 4, and conditions for the existence of at least one solution in each case have been stated. The reviewer [*Geometry of Einstein's unified field theory*, pp. 75–78, Noordhoff, Groningen, 1957; MR **20** #5067] gave a solution of the same in holonomic form for the index of inertia 2 and $D\neq 0$, which will remain similar in form for the indices of inertia 0 and 4 also. But this solution contains D as a factor in the denominator of some of its terms, and hence cannot be used for $D=0$. The object of this paper is to give solutions of the said equation in holonomic form for the degenerate cases $K+1=0$ and $3K-1=0$ of the first class when $D=0$, for the index of inertia 0 of $h_{\lambda\kappa}$ (in which case only $K+1$ can be zero) and for the index of inertia 0 and 4 of $h_{\lambda\kappa}$ (in which case only $3K-1$ can be zero) and to state conditions for the existence of at least one solution in each case. *V. Hlavatý* (Bloomington, Ind.)

Nguyen, Phong-Chau [Nguyen Phong Chau] 5613

Contribution à l'étude des théories du champ unifié du type théorie d'Einstein-Schrödinger. (English summary)

Ann. Inst. H. Poincaré 18, 303–357 (1964).

The author generalizes to some extent the Einstein-Schrödinger theory and proposes also some new physical interpretation of the variables occurring in the asymmetric theories. The main chapter headings of this rather comprehensive treatment are: (1) The difficulties encountered in the Einstein-Schrödinger theory; (2) The second-order approximate equations, and the conservation identities; (3) The Cauchy problem of the field equations; (4) Stationary unitary fields that are everywhere regular; (5) Physical interpretation, and the problem of (ponderomotive) motion; and (6) The static and spherically symmetric field of a charged particle.

P. G. Bergmann (New York)

Pimenov, R. I. 5614

An application of semi-Riemannian geometry to unified field theory. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 795–797.

The author shows that Einstein's gravitational field equations and both sets of Maxwell's equations are contained in the geometrical structure of a semi-riemannian manifold ${}^3V_5{}^4$ in which $g_i(5;\nu)=0$, $F_{ik}=2A_{[i;k]}$ and $A_i=g_{5i}/(g_{55})^{1/2}$ $(i,k=1,\cdots,4;\nu\leq 5)$.

A. H. Klotz (Liverpool)

Treder, Hans-Jürgen 5615

Eine Verallgemeinerung des Theorems von Einstein und Pauli.

Math. Nachr. **26** (1963/64), 353–359.

The theorem referred to in the title states that under certain boundary and regularity conditions there is no everywhere regular stationary solution of the Einstein vacuum field equations corresponding to a particle of non-vanishing mass. The author applies the technique of Einstein and Pauli to the case where the static space-time contains a world-line on which the metric has a vanishing determinant. He shows that this singular world-line may in some cases be identified with that of a monopole particle and gives an expression for the mass of the particle. *A. H. Taub* (Berkeley, Calif.)

Blitzer, Leon 5616

Synchronous and resonant satellite orbits associated with equatorial ellipticity. (Russian summary)

The Use of Artificial Satellites for Geodesy (Proc. First Internat. Sympos., Washington, D.C., 1962), *pp.* 52–61. *North-Holland, Amsterdam,* 1963.

The author considers orbits of such small eccentricity and inclination that the equations for the quantities expressing departures from circular motion and for the latitude can be considered to be linear in these quantities. Tesseral harmonics of the second order are considered. It is shown that, in general, the oscillations of the small quantities remain small, but that when the period of the satellite is 12 or 36 hours, the amplitudes of the induced oscillations increase linearly with time, due to resonance. The 24-hour satellite is another exception, and properties of the positions of stable and unstable equilibrium are discussed. *J. M. A. Danby* (New Haven, Conn.)

Close satellite orbits of an oblate planet (historical survey). (Russian summary)

The Use of Artificial Satellites for Geodesy (Proc. First Internat. Sympos., Washington, D.C., 1962), *pp.* 3–5. *North-Holland, Amsterdam,* 1963.

A brief comparison is made of the accuracy and simplicity of the satellite theories of Brouwer, the author, and Vinti. *J. M. A. Danby* (New Haven, Conn.)

Morando, B. 5618

Recherches sur les orbites de résonance. (English and Russian summaries)

The Use of Artificial Satellites for Geodesy (Proc. First Internat. Sympos., Washington, D.C., 1962), *pp.* 42–51. *North-Holland, Amsterdam,* 1963.

The author considers satellite orbits with periods $(q/p)24$ hours, where q and p are integers. Different tesseral harmonics are considered independently, and the method of von Zeipel, as used by Hori, is used to isolate the terms that would lead to small divisors. Principal attention is confined to the motion of the 24-hour satellite. The author emphasizes that effects of eight harmonics should be taken into account. *J. M. A. Danby* (New Haven, Conn.)

Vinti, John P. 5619

Zonal harmonic perturbations of an accurate reference orbit of an artificial satellite.

J. Res. Nat. Bur. Standards Sect. B **67B** (1963), 191–222.

The author's well-known reference orbit, the construction of which is based on the separability of a Hamilton-Jacobi equation in oblate spheroidal coordinates, accounts for the conventional $O(J_2)$ and $O(J_2^2)$ perturbations of an artificial satellite. In the present paper the author derives the $O(J_2^2+J_4)$ and $O(J_3)$ perturbations in Delaunay variables that affect his reference orbit. Essentially, the results are continued in those of Kozai [Astronom. J. **67** (1962), 446–461]. *I. G. Izsak* (Cambridge, Mass.)

A differential approximation for radiative transfer with application to normal shock structure.

Proc. 1963 Heat Transfer and Fluid Mech. Inst. (Calif. Inst. Tech., Pasadena, Calif., 1963), *pp.* 1–13. *Stanford Univ. Press, Stanford, Calif.,* 1963.

A differential approximation to one-dimensional gray radiative heat flux has been obtained which avoids the necessity of treating integro-differential equations. Various degrees of approximation lead from a moment method to various differential equations for the flux. The first two approximations are stated. The first approximation, equivalent to the Milne-Eddington approximation, is applied to the structure of a gray radiating normal shock wave with both viscosity and heat conductivity. It is found that two allowable starting slopes occur for the temperature-velocity profile, where in the non-radiating case there is only one. Linearization shows each slope to be related to a characteristic length for the shock, one associated with the collision and the other to the photon mean free path. The significance of these slopes in determining the shock profile is discussed as a function of shock strength, including the limits of no radiation, transparency, and opaqueness.

In an introductory discussion the author states that the conventional formulation of gas dynamics problems with

radiative transfer in terms of integro-differential equations "is not associated with some intrinsic action-at-distance of the radiation". This reviewer disagrees. The differential formulation arises from the assumption he uses: That the radiation field is nearly isotropic, so that an expansion in Legendre polynomials may be truncated after a few terms. In general, a hierarchy of differential equations is found, each one coupled with the next higher one. No rational truncation scheme (closure) seems evident unless anisotropy is small. This reviewer believes the expansion to be an asymptotic one in a sense analogous to that of the Chapman-Enskog expansion yielding partial differential equations asymptotic to the Boltzmann integro-differential equation for small Knudsen number. More physically, the integro-differential equation is an expression of the fact that radiative flux at a point comes from all over space, having been emitted elsewhere and, perhaps, absorbed and re-emitted along the way. The assumption of near isotropy, leading to the differential formulation rather than the conventional one, is formally equivalent to the substitution of an exponential function for an exponential integral as the kernel in the radiative heat flux integral. The relative error in this substitution grows linearly with the argument and hence becomes arbitrarily large for large argument. However, the integrated result for heat flux seems to be quite well approximated by this procedure. Thus, as an ad hoc approximation, the substitute kernel or differential approximation is a very useful and powerful tool, even when the radiation field is strongly anisotropic, as in shock wave. *I. M. Cohen* (Providence, R.I.)

★Astronomie. 5623

Volume publié sous la direction d'Evry Schatzman. Encyclopédie de la Pléiade, Vol. XIII.

Librairie Gallimard, Paris, 1962. xxiii + 1834 *pp*.

The strength of this book lies in its truly encyclopaedic coverage of astronomy; but though very many topics are discussed, the discussions are, on the whole, superficial. Formulas are often given which would bewilder the uninitiated, but also fail to satisfy the specialist. Nevertheless, there are some excellent descriptive articles, and the book is not unrewarding for the browser.

On large-scale instabilities during gravitational collapse and the evolution of shrinking Maclaurin spheroids.

Astrophys. J. **139** (1964), 1195–1216.

Author's summary: "The collapse of a rotating, pressureless, self-gravitating spheroid is computed and shown to be unstable against small second harmonic deformation throughout the period of collapse into a disk. The disk actually formed may thus be considerably elongated along a diameter. This may be significant in the formation of galaxies. The instability due to friction that occurs in the classical sequence of Maclaurin spheroids at their point of bifurcation with the Jacobi ellipsoids only develops if the spheroid is shrinking more slowly than the rate at which viscosity can dissipate the energy. Small tides raised by another body have little effect except when they resonate at a natural frequency of the spheroid. Chandrasekhar's virial tensor method can be used to discuss time-varying ellipsoids provided the velocities are linear functions of position."

papers of the original Russian volume were translations of English papers into Russian; they have now been translated into German.

Allen, W. R. 5629

Simple inventory models with bunched inputs.

Naval Res. Logist. Quart. **9** (1962), 265–273.

If N is a Poisson variable and $X_1, \cdots, X_N$ are independent random variables from the same population, then $S = X_1 + \cdots + X_N$ is a compound distribution whose d.f. is easily obtained. This note considers orders (output) and stock (input) arriving in a time period of length t to be "bunched" variables of this nature, with $\mathscr{E}(N) = \lambda t$ for some λ. If mean output and input are equal, the variance of the difference between output and input is considered as the parameter of interest and is listed for some simple compound distributions. It is noted that if transhipments in and out are considered, as further independent random inputs and outputs, their difference may be added to the stock-orders difference. There is no mention of any actual inventory system to which these elementary models apply: it is remarked that "this examination of an open loop system should aid in directing our attention to reasonable approaches in improving an inventory system by servo-control approaches", but we are not told how.

Bartholomew, D. J. 5630

A multi-stage renewal process.

J. Roy. Statist. Soc. Ser. B **25** (1963), 150–168.

Author's summary: "This paper derives the theory of a multi-stage renewal process and discusses two applications. The process consists of several self-renewing aggregates arranged in series. When a failure occurs in the ith stage it is replaced by an item already operating in the $(i-1)$st stage; the vacancy thus created is filled by a member of stage $(i-2)$ and so on. The main object of the analysis is to determine the failure rates in each stage and the transfer rates between stages. Two rules for selecting the item to be transferred are considered; in one case the selection is made at random, in the other the oldest member is selected. General methods for obtaining transient and equilibrium solutions are given for both rules. Simple explicit solutions are obtained when the life distribution is negative exponential and for certain other distributions. The application of the theory to the study of wastage and promotion in hierarchical organizations and to the determination of optimum industrial replacement schemes is briefly discussed."

W. F. Tyndall (Lancaster, Pa.)

Efron, Bradley 5632

Optimum evasion versus systematic search.

J. Soc. Indust. Appl. Math. **12** (1964), 450–457.

The author considers the following search-versus-evasion problem in the context of game theory. For his ith move Player I (the evader) chooses an integer m_i from $R = \{1, 2, \cdots, N\}$, and on his ith move Player II (the searcher) chooses a set S_i of M_i integers drawn from R. Each integer represents one of N separate rooms. Play terminates after n moves for each player or when II "finds" I (i.e., $m_i \in S_i$, for some i, $1 \leq i \leq n$), whichever occurs first.

Let P be a nondecreasing function on R. If Player II finds Player I on the j_0th move, II pays I $P(j_0)$ units; if there is no such j, then I receives $P(n+1)$. It is assumed that Player II's search is systematic, that is, the sets S_i are mutually disjoint. In this case, require $n \leq N$. By symmetry, II's optimal strategy is to choose with equal probability from among the permutations of $M_1 + M_2 + \cdots + M_n$ $(\leq N)$ distinct elements of R.

The main result of the paper establishes that Player I's optimal strategy is to choose with equal probability from among the permutations of n distinct elements of R. Thus Player I need never employ his option to return to a room which he has previously occupied.

Giammo, T. P. 5633

On the probability of success in a sudden death search with intermittent moves confined to a finite area.

SIAM Rev. **5** (1963), 41–51.

Red and Blue are two guerrillas searching for each other according to the following rules: Blue remains at a fixed point in his operating region for a time t_m and then jumps instantaneously to any other point of the region (with equal probability) where he stays for a further time t_m, then moves again, and so on. His first move is equally likely to be at any point in $(0, t)$. Similarly for Red. Independently and simultaneously, each searches the other's region randomly at a uniform rate so that, apart from the initial period, each scans a fixed proportion of the other's region before the latter jumps and then the search effectively starts again from scratch. This leads directly to the p.d.f. of the time before Red discovers Blue, and conversely: These are of course approximately exponential when the chance of discovery in any period is low. The usual actuarial formula is used then to give an expression for the chance that Blue discovers Red before Red discovers Blue, and conversely.

This model for guerrilla behaviour is attributed to Chaiken et al.; no justification is attempted in this paper.

★Elements of linear programming. With economic applications.

Griffin's Statistical Monographs & Courses, No. 15.

Hafner Publishing Co., New York, 1964. 126 *pp.* \$4.95.

This short, inexact, and often misleading book is intended to be an introduction to linear programming for students of economics. The book fails in presenting both "theory" and "applications".

Part I, "Theory", begins by considering a simple example which is solved graphically and by a labored use of a simplex method. There follows a general discussion of the linear programming problem and a simplex method for its solution. However, this discussion is misleading (e.g., there is no explicit recognition of the fact that a problem may not have a solution), and contains false statements (e.g., "the maximizing- or minimizing-point ... must be a vertex" is "Proposition I"), together with erroneous proofs. Duality is treated as a mystical gift (e.g., "the remarkable phenomenon").

Part II, "Applications", considers five simple linear programs arising in various applied contexts. Unfortunately, the potential uses and interpretations of the dual problem are not adequately discussed—in fact, not discussed at all in the first two examples dealing with a transportation problem and an activity analysis problem where interpretations are easily given.

Appendices, one pointing out the need for integer solutions in certain formulations and another dealing with convex programming, complete the book. Only three references to published work in the field of mathematical programming are made. *M. L. Balinski* (Princeton, N.J.)

Hoáng Tuy [Hoàng, Tuy] 5637

Sur une classe des programmes non linéaires.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 213–215.

This brief note is a French version of the author's earlier work in Vietnamese [Publ. Sect. Phys. Math. Comité État Sci., No. 1 (1963)]. It is suggested that the simplex method is applicable to the following bounded-variable programming problem. Minimize $f(x)$ subject to

$$\sum_{j=1}^{n} A_j x_j = B, \qquad 0 \le x_j \le \alpha_j \ (j = 1, \cdots, n),$$

where A_j, $B \in R^m$, $\alpha_j > 0$ $(j = 1, \cdots, n)$ and the numerical function f, defined on R^n, satisfies the property:

$$\text{(M)} \qquad \varphi(\lambda) = f(\lambda x + (1-\lambda)y)$$

is monotone in the interval $0 \le \lambda \le 1$ for each pair of points x, y belonging to the constraint set P of the problem. From the obvious property

$$(\mathrm{M}_1) \qquad f(\lambda x + (1-\lambda)y) \ge \min\{f(x), f(y)\}$$

for all $x, y \in P$ and $\lambda \in [0, 1]$, it follows that the minimum of $f(x)$ over P is attained at an extreme point of P. However, certain assertions depend on the claim that (M_2) if $x, y \in P$ and $f(x) \le f(y)$, then for all $\lambda \le 0$, $f(x) \le f(\lambda x + (1-\lambda)y)$. This inequality need not be true if $f(x) = f(y)$.

The article contains allusions to problems such as homogeneous linear fractional programming to which the hypotheses apply. However, no attempt is made to relate the present work to others in the field [see, for example, P. C. Gomory and R. E. Gilmore, Operations Res. **11** (1963), 863–888; in particular, note page 882]. *R. W. Cottle* (Holmdel, N.J.)

Kall, Peter 5638

Über eine Anwendung endlicher Markov-Ketten in der linearen und nichtlinearen Programmierung.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **3**, 89–109 (1964).

First, a Markov chain P is defined, and the necessary and sufficient condition is given for the existence of $P^* = \lim_{m\to\infty} P^m$. This is followed by a description of a program that has been developed to meet the demands of a certain material in a number, r, of successive years at minimum total cost. The demand in year i is to a certain extent determined by that year's political situation. These political situations are the external states of the system which are outside the control of the policymaker. p_{ij} is the probability that this year's political situation, E_i, will be E_j next year (it is, of course, possible that $E_j = E_i$); the p_{ij}'s are elements of a transfer matrix P which is square. To meet the demand in each successive year the material can be imported from foreign countries or produced at home. In the latter case, the combined capacity of the domestic plants is the determining factor; this capacity can be expanded or contracted (by not replacing what is obsolete or worn out). What is imported or produced domestically in each year is added to an existing stockpile, and what is needed to meet the demand is taken out of it. The various possible levels of the stockpile and the combined capacity of the domestic plants are the internal states of the system; they are under control of the policymaker. The objective is to minimize the total cost of the program given by the following recursive system of functional equations:

$$F_{E_i,k,r'} = \min_{k'}\Big(C_{E_i,k,k'} + v \sum_{j=1}^{K} p_{ij} F_{E_j,k',r'-1}\Big),$$

$$r' = 1, 2, \cdots, r,$$

where $F_{E_i,k,r'}$ is the total cost of a program starting with an external state E_i and an internal state k covering a period of r' years; $C_{E_i,k,k'}$ is the cost of that program in year r' (which is its first year since the years are counted backwards in time); k' is the internal state of the system at the end of year r' = the beginning of year $(r'-1)$; v is the discount factor; and p_{ij} is the probability that political situation E_i in year r' will be E_j in year $(r'-1)$; the probability of no change in political climate is then given by p_{ii}.

In the paper it is first proved that, due to the fact that the discount factor $v<1$, the total cost of the program $F_{E_i,k,r}$ will tend to a limit $F_{E_i,k}$ when the number of years, r, covered by it increases beyond all bounds. Then it is shown that if all elements of the transfer matrix P are strictly positive, the system will tend to a particular internal state for each possible external state. It is also shown that this "convergence in policy-space" will take place if the transfer matrix P is completely ergodic and at least one of the $p_{ii}>0$. Finally, it is shown that the same can be said of situations in which the restrictions, defining the requirements, and/or the cost functions are nonlinear. *H. F. Karreman* (Madison, Wis.)

Lur'e, A. L. 5639

An algorithm for solving a transportation problem by approximating by conditionally optimal plans. (Russian)

Vyčisl. Mat. 7 (1961), 151–160.

For the so-called transportation problem (viz., to find x_{ik}, $i=1,\cdots,n$, $k=1,\cdots,m$, such that $\sum_k x_{ik}=a_i$, $\sum_i x_{ik}=b_k$, $x_{ik}\geq 0$, $\sum_{i,k} c_{ik}x_{ik}=\min$, a_i, b_k, c_{ik} are given real numbers, a_i and b_k positive, $\sum_i a_i=\sum_k b_k$) the author adapts ideas from L. V. Kantorovič's linear-programming algorithm called "approximation by conditionally optimal plans" [*Mathematical methods of organization and planning of production* (Russian), Izdat. Leningrad. Goz. Univ., Leningrad, 1939; Dokl. Akad. Nauk SSSR **115** (1957), 441–444; MR **20** #769], expounds them in a fully self-contained fashion, and points out the resemblance to the (American-developed) so-called Hungarian method.

Consider a set of values x_{ik} (the "conditionally optimal plans") such that, if $c_{i_rk_p}>\min_i c_{ik_p}$, then $k_p=0$ in $x_{i_rk_p}$, $\sum_k x_{ik}\leq a_i$, $\sum_i x_{ik}\leq b_k$, $\sum_{i,k} x_{ik}=\max$. Find $N_k=b_k-\sum_i x_{ik}$. If $N_k=0$, end. If $N_k>0$, partition the index set $\{i\}$ into $\{i'\}$ and $\{i''\}$: If there is a k such that i_r satisfies $c_{i_rk}=\min_i c_{ik}$ and $N_k>0$, then $i_r\in\{i''\}$. Likewise, if there are i'' and k such that $c_{i_rk}=\min_i c_{ik}$, and $x_{i''k}>0$, then $i_r\in\{i''\}$. Other i belong to $\{i'\}$. Find $d=\min_{i',k'}(c_{i'k'}-\min_i c_{ik'})$, where k' is a k for which the number in the parentheses is positive for any i'. Every c_{ik} is augmented by d. With these improved c_{ik}, the routine begins anew.

The author says the method is most simple for small n and m. For larger n and m there are complications, arising from a fast increasing number of necessary iterations, which require certain complicated modifications of the routine. Practical applications of the method were shown by A. Aleksandrov, A. Lur'e, and Ju. Oleĭnik.
E. M. Fels (Pittsburgh, Pa.)

Weiss, George H. 5640

Optimal periodic inspection programs for randomly failing equipment.

J. Res. Nat. Bur. Standards Sect. B **67B** (1963), 223–228.

A system is assumed to fail in accordance with a known but arbitrary distribution of failure time. Both inspection and replacement take time; in addition, there is a probability, possibly positive, that any given inspection will fail to detect the failure. The problem posed is to choose that periodic inspection policy which minimizes expected down time of the system. (As the author notes, the optimal policy need not, in general, be periodic, but he seeks the optimum only among this restricted class because of its operational convenience.) It is assumed that replacement occurs only after failure is detected on an inspection. The optimal solution is found for the cases where inspection and replacement times are deterministic and where they are exponentially distributed. Some brief comparisons are made between this policy and the no-inspection (replacement at fixed time) policy.
K. J. Arrow (Stanford, Calif.)

Gomory, R. E.; Hu, T. C. 5641

Synthesis of a communication network.

J. Soc. Indust. Appl. Math. **12** (1964), 348–369.

From the authors' summary: "A communication network is a set of nodes connected by arcs. Every arc has associated with it a non-negative number called the branch capacity which indicates the maximum amount of flow that can pass through the arc. A communication network must have large enough branch capacities such that all message requirements (which can be regarded as flows of different commodities) can reach their destinations simultaneously. In general, these requirements vary with time. The present paper gives algorithms for min-cost synthesis of a communication network which is able to handle simultaneous flows of all time periods."

The time-varying synthesis problem for an m-arc network is first formulated as a linear program with a reasonable number of rows and an enormous number of columns. The authors exploit the special structure of this large linear program using decomposition methods to show that the problem can be reduced to a linear programming calculation involving only one $m\times m$ matrix, together with auxiliary $m\times m$ linear programming calculations of the type treated by L. R. Ford, Jr. and D. R. Fulkerson [Management Sci. **5** (1958), 97–101; MR **20** #4342].

A modest example is solved using both the primal and dual algorithms developed in the paper. It is stated that a synthesis problem for a ten-node twenty-arc network with two time periods was solved in ten minutes on an IBM 7094 using the dual method.

A useful survey of recent results in this area together with their references is included in the paper.

A remark on S. I. Zuhovickiĭ's paper, "On a problem of piecewise linear programming". (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 968–969.

It is shown that the minimization problem discussed in a paper by Zuhovickiĭ [same Ž. **3** (1963), 599–605; MR **28** #1741] is easily reduced to a standard linear programming problem. This was pointed out in the cited review of Zuhovickiĭ's paper. *L. Weiss* (Ithaca, N.Y.)

Rosen, J. B. 5643

Primal partition programming for block diagonal matrices.

Numer. Math. **6** (1964), 250–260.

Under consideration here are the l-block dual linear program (1) maximize $b_0'y+\sum_{i=1}^{l} b_i'x_i$ subject to $D_i y'+A_i'x_i\leq c_i$, $i=1,\cdots,l$, and the corresponding primal problem (2) minimize $\sum_{i=1}^{l} c_i'u_i$ subject to $\sum_{i=1}^{l} D_iu_i=b_0$, $A_iu_i=b_0$, $u_i\geq 0$, $i=1,\cdots,l$. (Lower case letters denote

column vectors and capital letters denote matrices. Transposition is indicated by a prime.) The following two paragraphs—excerpted (mutatis mutandis) from the author's introduction—provide an ample brief description of the algorithm.

Since (1) and (2) are dual linear problems, an optimal solution to either one also gives an optimal solution to the other. The method of solution described here gives a sequence of feasible solutions to (1) which are obtained by solving subproblems of (2). At each cycle a test is made for a complete problem optimum solution. When this test is satisfied, the optimum solution to (1) and (2) is given. If the test is not satisfied, a basis change is made in every non-optimal block and a new feasible solution is obtained with a non-decreased function value. If a finite solution exists, it is obtained in a finite number of cycles.

During the first cycle, l linear programming subproblems with m_i equations in the ith subproblem, where m_i is the number of equations in the ith block of (2), are solved. In every subsequent cycle, only a single linear programming problem with s equations, where s is the number of coupling equations in (2), is solved. The size of all subproblems remains unchanged throughout the solution procedure.

In addition to a demonstration of the validity of algorithm, experience with an IBM 7090/7094 computer program based on the algorithm is reported. Results are summarized on six test problems, the largest of which is a fifteen-block problem with 930 equations and 1200 variables. *R. W. Cottle* (Holmdel, N.J.)

Remark on a paper by F. W. Sinden.

J. Math. Anal. Appl. **9** (1964), 162–163.

This note clarifies a point concerning the treatment of linear programming as a special case of quadratic programming given in Section VI of Sinden [same J. **5** (1962), 378–402; MR **26** #3523]. *E. M. L. Beale* (London)

Charnes, A.; Cooper, W. W.; Kortanek, K. 5645

Duality in semi-infinite programs and some works of Haar and Carathéodory.

Management Sci. **9** (1962/63), 209–228.

Authors' summary: "By constructing a new infinite-dimensional space for which the extreme point-linear independence and opposite sign theorems of Charnes and Cooper continue to hold, and, building on a little-known work of Haar (herein presented), an extended dual theorem comparable in precision and exhaustiveness to the finite space theorem is developed. Building further on this, a dual theorem is developed for arbitrary convex programs with convex constraints which subsumes in principle all characterizations of optimality or duality in convex programming. No differentiability or constraint qualifications are involved, and the theorem lends itself to new computational procedures."

Mangasarian, O. L.; Rosen, J. B. 5646

Inequalities for stochastic nonlinear programming problems.

Operations Res. **12** (1964), 143–154.

This paper extends Madansky's inequalities for stochastic linear programming problems [Management Sci. **6** (1959/60), 197–204; MR **22** #1457] to nonlinear programming problems under appropriate convexity and continuity assumptions. The authors point out that, since their problems are nonlinear anyway, the calculation of one upper and one lower bound may involve only slightly more effort than two solutions of a deterministic problem of the same size. *E. M. L. Beale* (London)

★Mathematical theories of traffic flow.

Academic Press, New York-London, 1963. xi + 242 *pp.* $9.00.

This book, by setting out in a leisurely way the basic problems encountered by those concerned with a mathematical formulation of traffic flow, should persuade many readers to participate in the further development of this rather difficult subject. It is Volume 7 of the series of monographs on "Mathematics in Science and Engineering" and is written in a style which should make its contents quite accessible to the engineer-reader. The probabilist should not expect sophistication, which would be out of place in a book of this kind, and should not be deterred by the shortcomings of the mathematical presentation (e.g., an elliptic definition of the Poisson process on page 38, and a mysterious reference to Bayes on page 43). Chapter 1 summarises "Probability and Statistics" and Chapter 2 summarises "Theory of Queues"; most readers will know all this already. The book really begins with Chapter 3, "Fundamental Characteristics of Road Traffic", which deals with the flow-concentration diagram and the theory of car-following. Chapter 4, "Arrangement of Cars on a Road", is a study of the point-processes which arise in this context. Chapter 5, "The Simple Delay Problem", discusses delays to pedestrians trying to cross a road, and delays to vehicles at light-controlled intersections, etc. The "Miscellaneous Problems" dealt with in Chapter 6 include "left turning" (="right turning" in some parts of the world), "multi-laned highways", "sequences of traffic controls", "parking", "merging", "bottlenecks", and "the rush hour". The book concludes with a final chapter on "A Two-lane Road" and a discussion of "overtaking". There is a large bibliography.

The n-person bargaining game.

Advances in game theory, *pp.* 547–575. *Princeton Univ. Press, Princeton, N.J.*, 1964.

For a class of games in which strategic problems do not complicate the bargaining features, the author simplifies Harsanyi's first general bargaining theory [*Contributions to the theory of games*, Vol. IV, pp. 325–355, Princeton Univ. Press, Princeton, N.J., 1959; MR **21** #4062]. It should be noted that Harsanyi has substantially revised his approach [Internat. Economic Rev. 4 (1963), 194–220], avoiding the reviewer's example [Bull. Amer. Math. Soc. **66** (1960), 70–73; MR **22** #13315], where one player can do better fighting all the rest than sitting down to bargain with them in the manner proposed. The author's theory gives the same paradoxical solution (15, 15, 0) to the same example. *J. R. Isbell* (New Orleans, La.)

Cirlin, A. M. 5651

Determination of the spectral density of random processes as a problem of approximating a function with respect to its estimate. (Russian. English summary)

Avtomat. i Telemeh. 25 (1964), 1191–1197.

The determination of the spectral density of random processes by means of a decomposition of its estimate from a finite realization in a system of orthogonal functions is subject to the following conclusion. The accuracy of determination of coefficients of the decomposition depends on the scalar product of the dispersion of this estimate and the weight function of the decomposition. In particular, the accuracy increases when this scalar product decreases.

Additional conclusions are: (1) calculation of spectral density can be simplified by determining the coefficients of the decomposition in the selected system of orthogonal functions (instead of some selected ordinates); (2) by a choice of an adequate weight function one can diminish the effect of the lack of accuracy in the determination of spectral density; and (3) the method of moments suggested in a number of publications is not adequate for the determination of the random processes based on short realizations and a variable mathematical expectation.

Hackett, C. M., Jr. 5652

Word error rate for group codes detected by correlation and other means.

IEEE Trans. Information Theory IT-9 (1963), 24–33.

In this paper, the author derives general expressions for the probability of word error for several encoding/detection schemes using group codes. Correlation detection, digital decoding, Wagner codes, Wagnerised codes and direct transmission are the schemes treated, and in each case expressions are derived for the case where the additive channel noise is white and Gaussian. A good indication of the relative amounts of power required by two schemes operating at the same error rate is available from an asymptotic relationship as the signal to noise ratio approaches infinity. Numerical results are presented for three easily implemented codes.

Jelinek, Frederick 5653

Loss in information transmission through two-way channels.

Information and Control 6 (1963), 337–371.

A discrete two-way channel, related to the pioneering work of Shannon in 1961 [Proc. Fourth Berkeley Sympos. Math. Statist. and Prob., Vol. I, pp. 611–644, Univ. California Press, Berkeley, Calif., 1961; MR 24 #B1250] and which has been further developed by Fano and the present author [Fano, *Transmission of information*, M.I.T. Press, Cambridge, Mass., 1961; MR 24 #B442; Jelinek, IEEE Trans. Information Theory IT-10 (1964), 5–17; MR 29 #4615] is considered. Certain restrictions are put on the probability. The terminals are connected to finite-memory stationary signal sources. These signal sources generate channel inputs depending on sequences of past outputs and inputs. A number of interesting results are deduced which appear in seven theorems and some of their corollaries given in the paper. The following extract from the author's summary will give some idea of the results obtained.

"Expressions for average information transmission rates in the left-to-right and right-to-left directions can be developed and their sum will be a simple information measure. When mutually independent messages are to be transmitted in opposite directions through the channel, it is desirable that they be encoded into sequences of strategy functions which, together with the received signals, constitute inputs to a transducer whose outputs are the channel input signals. The message source-encoder-transducer combinations are stochastically equivalent to signal sources whose outputs are governed by appropriate probabilities. We can interpret the transducer-channel combination as a derived two-way channel whose inputs are the strategy functions and whose outputs are the outputs of the underlying channel. Expressions for the information transmission rate through the two directions of the derived channel are developed and are compared to the expressions for the average information about outputs of the equivalent signal sources, transmitted through the underlying two-way channel. The values of the former expressions are found to be less than or equal to the values of the latter, the difference constituting a 'coding information loss'. A condition on the transmission probabilities enables us to define a class of lossless channels. Similarly, another class is defined having the property that, regardless of the strategy code used, the information transmitted through the derived channel will be strictly less than the information transmitted through the underlying channel. The consequences of the above results on the random selection of message codes are

discussed. It is shown that one can obtain the number of variables to be optimized when best random codes for lossy channels are desired, by using the number of variables for lossless channels as an exponent to the product of the size of the input and output signal alphabets. For the lossy channel class a simplified encoding procedure must in practice be applied, but as can be demonstrated, it will not yield optimal codes."

Karmazin, M. A. 5654

Solution of a problem of Shannon. (Russian)

Problemy Kibernet. No. 11 (1964), 263–266.

Let A and B be discrete memoryless channels with input [output] alphabets of the same size, and let P and Q be the matrices of their respective channel probability functions. Let $\lambda(n, D|A)$ and $\lambda(n, D|B)$ be, respectively, the minimum average probabilities of error for codes of length D and word length n. Shannon [Information and Control **1** (1958), 390–397; MR **20** #6952] proved that if

$$A = \sum_{\alpha,\beta} g_{\alpha\beta} F_\alpha B G_\beta, \qquad g_{\alpha\beta} \geq 0, \qquad \sum_{\alpha,\beta} g_{\alpha\beta} = 1,$$

where F_α and G_β are stochastic matrices, then, for all n and D, $\lambda(n, D|B) \leq \lambda(n, D|A)$. The author proves that the converse is not true.

Rozen'blat-Rot, M. [Rosenblatt-Roth, M.] 5655

The concept of entropy in probability theory and its applications in the theory of transmission of information in communication channels. (Russian. French summary)

Teor. Verojatnost. i Primenen. **9** (1964), 238–261.

Let (S_i, Σ_i, μ_i) be σ-finite measure spaces, $i \in I$ the set of all integers. Let $(S, \Sigma, \mu) = \times_{i\in I} (S_i, \Sigma_i, \mu_i)$ and if $\alpha \subset I$, let $(S^\alpha, \Sigma^\alpha, \mu^\alpha) = \times_{i\in\alpha} (S_i, \Sigma_i, \mu_i)$. A stochastic process (not necessarily stationary) on (S, Σ) may be considered as a system of probability measures P^α on different Σ^α, $\alpha \subset I$. It is assumed that each P^α is absolutely continuous with respect to the restriction of μ to Σ^α, and let $\pi^\alpha = dP^\alpha/d\mu$ be the corresponding Radon-Nikodým derivative. The differential entropy of the process at time t is defined to be, if it exists, the limit as $n \to \infty$ of the expression $-n^{-1} \int_S \log \pi^{\alpha_n} d\mu$, where $\alpha_n = [t, t+n-1]$. This notion is used to obtain extensions of coding theorems of Shannon, McMillan and Feinstein.

Golomb, S. W.; Posner, E. C. 5657

Rook domains, Latin squares, affine planes, and error-distributing codes.

IEEE Trans. Information Theory **IT-10** (1964), 196–208.

Authors' summary: "A problem originally suggested in the context of genetic coding leads naturally to the concept of rook packing and error-distributing codes. It is shown how various concepts in the theory of Latin squares, and also in coding theory, are best expressed in the form of questions about the placing of rooks on k-dimensional hyperchessboards of side n. A new species of combinatorial design suggested by this is the concept of optimal coloring. It is shown that the optimal colorings in certain cases correspond to duals of desarguian projective planes. Light is thereby shed on the problems of the existence of both finite projective planes and close-packed single-error-correcting codes. In particular, the existence of a certain close-packed nonbinary single-error-correcting code, listed by Golay as the first unknown case, has been ruled out by a well-known result concerning Latin squares."

Massey, James L. 5660

Reversible codes.

Information and Control 7 (1964), 369–380.

A code is defined to be reversible if its code-word set is invariant under a reversal of the digits in each code word. Such codes may have application in certain data storage and retrieval systems. It is shown that cyclic codes and convolutional codes are reversible when and only when their code-generating polynomials are self-reciprocal. Reversible codes are quite rare therefore, but it is shown that an important subclass of the Bose-Chaudhuri codes consists entirely of reversible codes. Techniques are developed by which any nonreversible cyclic code can be converted into a reversible cyclic code with at least as much error-correcting power, but at the cost of increased code redundancy. The redundancy of the derived code is at most twice that of the original code, and the derived code can be decoded by a decoder constructed for the original code.

Similarly, it is shown how any nonreversible convolutional code can be converted into a reversible convolutional code with at least as much error-correcting power, but at the cost of increased code constraint length. Again the derived code can be decoded by substantially the same decoder as for the original code.

Vasil'ev, Ju. L. 5661

On ungrouped, close-packed codes. (Russian)

Problemy Kibernet. No. 8 (1962), 337–339.

In this note an alternative method for constructing close-packed $(n, 3)$-codes is presented. A lower bound on the ratio of the number of different strongly ungrouped close-packed codes to the number of all grouped $(n, 3)$-codes is derived; strongly ungrouped codes mean those which are not grouped or are not shifts of grouped codes.

In particular, the conjecture of Shapiro and Slotnick [IBM J. Res. Develop. **3** (1959), 25–34; MR **20** #5092] on the existence of essentially one close-packed (n, d)-code for a given n and d is disproved.

This last result was also announced by the author in another paper [Dokl. Akad. Nauk SSSR **142** (1962), 263–265] in connection with the theory of disjunctive normal forms.

S. Kotz (Toronto, Ont.)

Amar, V.; Putzolu, G. 5662

On a family of linear grammars.

Information and Control 7 (1964), 283–291.

An even linear grammar (ELG) is a linear grammar in which the productions are all of the form

$$\delta \to \varphi,$$
$$\delta \to \varphi\delta'\varphi' \qquad \text{with } |\varphi| = |\varphi'|,$$

where δ, δ' are auxiliary letters, φ, φ' are terminal words and $|\varphi|$ denotes the length of φ. It is easily seen that the subsets of the free monoid Σ^* (where Σ is finite) produced by ELG's properly include the regular sets. Nonetheless, these special linear languages have a number of properties similar to regular sets.

Define a quasi-congruence relation on Σ^* as an equivalence relation R on Σ^* with the property

$$(\varphi, \psi) \in R \Rightarrow (\forall\varphi', \varphi'')_{\Sigma^*}[|\varphi'| = |\varphi''| \Rightarrow (\varphi'\varphi\varphi'', \varphi'\psi\varphi'') \in R].$$

Every even linear language is the union of some equivalence classes of a finite index quasi-congruence relation on Σ^*, and conversely. It is shown that the even linear languages are exactly those sets recognized by finite automata which scan a tape starting from the center and proceeding outward in both directions at the same time.

A statistical self-adjusting model. I. (Russian. English summary)

Avtomat. i Telemeh. 25 (1964), 1442–1450.

Author's summary: "The theory of statistical decision functions is applied to the design of self-adjusting models. To deduce basic correlations the notions of the dual control theory are used."

Bellman, Richard; Bucy, Richard 5664

Asymptotic control theory.

J. Soc. Indust. Appl. Math. Ser. A Control **2** (1964), 11–18.

The authors initiate the discussion of the problem of minimizing the functional

$$(*) \qquad J(u) = \frac{1}{2}\int_0^T (u^2 + L(x))\,dt$$

over all functions u, where $\dot{x} = f(x) + u$, $x(0) = c$. Let $V(c, t) = \min_u J(u)$. Then, $V(c, T)$ is increasing in T and uniformly bounded if $f(x) = ax$ and $L(x)$ satisfies certain mild restrictions. Since the existence of a sufficiently smooth solution to the partial differential equation

$$(**) \qquad V_T = \tfrac{1}{2}L(c) + acV_c - \tfrac{1}{2}V_c^2$$

is a sufficient condition for the variational problem $(*)$ to have a solution, an explicit solution to $(**)$ subject to the boundary conditions

$$V(c, T)\,|_{T=0} = 0, \qquad a < 0,$$
$$V(c, T)\,|_{T=0} = ac^2, \qquad a > 0,$$

is obtained. Further problems are suggested.

Krivenkov, Ju. P. 5669

Sufficiency of the maximum principle for a linear problem of dynamic programming. (Russian)

Dokl. Akad. Nauk SSSR **156** (1964), 1277–1280.

Das Problem optimaler Prozesse bei beschränkten Phasenkoordinaten wird im Buch von L. S. Pontrjagin, V. G. Boltjanskiĭ, R. V. Gamkrelidze und E. F. Miščenko [*Mathematische Theorie optimaler Prozesse* (russisch), Fizmatgiz, Moskau, 1961; MR **29** #3316a; englische Übersetzung, Interscience, New York, 1962; MR **29** #3316b; deutsche Übersetzung, Oldenbourg, München, 1964; MR **29** #3316c] behandelt. Die Arbeit gibt hinreichende Bedingungen dafür, damit die Linearizierung der Aufgabe eine Lösung hat. Diese Linearizierung fällt mit der linearen Aufgabe der dynamischen Programmierung zusammen [R. Bellman, *Dynamic programming*, Princeton Univ. Press, Princeton, N.J., 1957; MR **19**, 820].

Z. Daróczy (Debrecen)

Kudrevič, Ja. [Kudrewicz, J.] 5670

Stability of non-linear systems with feedback. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1145–1155.

The author defines a system by the input-output functional relation $y=\Gamma(x)$, where x is the input and y is the output of the system. He then defines the pseudo-norm

$$\|x\| = \lim_{T\to\infty}\left[\frac{1}{T}\int_0^T |x(t)|^2\,dt\right]^{1/2},$$

which may be regarded as the average power of the signal x. He considers a system to be stable "in the energy sense" if $\|\Gamma(x)\|=0$ for all inputs x such that $\|x\|=0$. He introduces the gain

$$|\Gamma| = \sup_{x\in E}\frac{\|\Gamma(x)\|}{\|x\|},\qquad E=\{x:\|x\|<\infty\}.$$

The rest of the paper is based on the theorem: "If the gain $|\Gamma|$ of the open-loop system Γ is less than one, then the closed-loop system with input z described by the equation $x=\Gamma(x)+z$ is stable in the energy sense". After proving this theorem he proceeds to calculate the gain $|\Gamma|$ for a number of nonlinear systems obtaining, among other results, the well-known circle criterion for a linear feedback system with a time-varying gain element and a particular case of the Popov stability criterion. The informed reader will recognize a substantial similarity between this work and the work of I. Sandberg and G. Zames (see, e.g., G. Zames [Proc. Nat. Electronics Conf., Vol. 20, pp. 725–730, Nat. Electronics Conf., Inc., Chicago, Ill., 1964] and I. Sandberg [ibid., pp. 737–741; Bell System Tech. J. **43** (1964), 1581–1599; MR **30** #1416; ibid. **43** (1964), 1601–1608; 1815–1817]).

E. Polak (Cambridge, Mass.)

Langenhop, C. E. 5671

On the stabilization of linear systems.

Proc. Amer. Math. Soc. **15** (1964), 735–742.

The results of Romanenko [Dopovidi Akad. Nauk Ukraïn. RSR **1962**, 863–867; MR **26** #432] and Berezanski on stabilizable systems of differential equations are generalized. Define a square matrix of complex elements by $G=\begin{pmatrix}A & B\\ P & Q\end{pmatrix}$, where A is n-by-n, Q is m-by-m, and B and P are correspondingly sized. Let $S_r=\{\mu_k: k=1,2,\cdots,r\}$, where the (complex) μ_k need not be distinct. Take h to be the rank of the matrix $H=(B, AB,\cdots, A^{n-1}B)$. The principal result is that $h\geqq r-m$ is a necessary and sufficient condition that, for each S_r, there exist P and Q such that the spectrum of G contains S_r.

The theorem is applied in specialized form to systems of differential equations $dx/dt=Ax+bu$, $du/dt=px+qu$, where $G=\begin{pmatrix}A & b\\ p & q\end{pmatrix}$, q a complex scalar. The system (A,b) is "stabilizable" if, given a non-empty set S of $n+1$ or fewer numbers, p and q can be chosen so that G has S as its spectrum. Then (A,b) is stabilizable if and only if $b, Ab,\cdots, A^{n-1}b$ are linearly independent. In particular, if (A,b) is a control system with state x and control u, the spectrum of G can be made to lie in the left half-plane, so that $x(t)\to 0$ and $u(t)\to 0$ as $t\to\infty$.

Pyškin, I. V. 5672

An exact method for calculating transient processes and stability of sampled-data systems with finite sampling time. (Russian. English summary)

Avtomat. i Telemeh. **24** (1963), 1303–1316.

Author's summary: "Sampled-data systems with finite sampling time are analysed. With the help of the method of 'solution sewing' used for the solution of the canonical equations of the system corresponding to closed and open states of the key, there are obtained difference equations describing the system, and then the process at the system output. The process image is obtained as a ratio of two determinants whose elements are simple root functions of closed and open systems. The stability of such systems is considered."

Rapoport, I. M. 5673

On the stability of control processes. (Russian)

Dokl. Akad. Nauk SSSR **159** (1964), 288–291.

The author wishes to examine the stability of the linear time-varying feedback system described by the equations

$$(1)\qquad \begin{aligned} dx/dt &= A(t)x+a(t)u, \qquad v = (b(t), x), \\ u &= \int_{-\infty}^{t} v(t')r(t-t', t')\,dt'. \end{aligned}$$

In order to do this, he makes use of the "slow time" concept introduced by N. M. Bogoliubov and N. M. Krylov and writes his equations in the form

$$(2)\qquad \begin{aligned} dx/dt &= A(\tau)x+a(\tau)u, \qquad v = (b(\tau), x), \\ u(t) &= \int_{-\infty}^{t} v(t')r(t-t', \tau')\,dt', \end{aligned}$$

where $\tau=\varepsilon t$ is the slow time. He then seeks a solution of (2) in the form $x(t)=y(\tau)\exp\theta(t)$, $\theta'(t)=\lambda(\tau)$, $\|y(\tau)\|=\sqrt{(y(\tau), \overline{y(\tau)})}=1$. For $\varepsilon=1$ the norm of such a solution satisfies the differential equation $d\|x\|/dt=\operatorname{Re}\lambda(t)\|x(t)\|$, and hence the author uses as a criterion of local stability the following inequality: $\operatorname{Re}\lambda(t)<0$. The author computes the solution of (2) by an iterative method which results in a series representation for $\lambda(t)$, and then considers the first few terms of this series only.

Dreyfus, Stuart E. 5674

Some types of optimal control of stochastic systems.

J. Soc. Indust. Appl. Math. Ser. A Control **2** (1964), 120–134.

Although the results are not new, this paper has pedagogical value for its illuminating discussion of the effects of various control philosophies on three simple stochastic control situations. The continuous parameter examples are

$$\text{(I)}\qquad dx = (ax+bu)\,dt+dz, \quad \text{Error} = E\int_0^T u^2\,dt+Ex^2(T),$$

$$\text{(II)}\qquad dx = u\,dz, \qquad\qquad \text{Error} = Ex^2(T),$$

where z is a Wiener process and T is fixed. The author computes and compares the controls and errors for the (i) optimal "open-loop" control, (ii) optimum "open-loop" control re-initialized at each instant of time, and (iii) the feedback control derived from the principle of optimality.

H. J. Kushner (Providence, R.I.)

Egorov, A. I. 5675

Optimal control of processes in certain systems with distributed parameters. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 613–623.

Author's summary: "A case of the optimum control problem is considered when the process is described by differential equations with second-order partial derivatives. Necessary criteria for optimality are found. In the case when the differential equations are linear, the criteria found are locally sufficient."

W. H. Fleming (Providence, R.I.)

Fadden, Edward J.; Gilbert, Elmer G. 5676

Computational aspects of the time-optimal control problem.

Computing Methods in Optimization Problems (*Proc. Conf., Univ. California, Los Angeles, Calif.*, 1964), pp. 167–192. *Academic Press, New York*, 1964.

Given the system $\dot{x}=F(t)x+b(t)u$, $x(t_0)=x_0$, it was shown by Neustadt [J. Math. Anal. Appl. 1 (1960), 484–493; MR 23 #B1612] and Eaton [ibid. 5 (1962), 329–344; MR 25 #4214] that the minimal time regulator problem can be solved via the maximization of $T(\eta)$, where

$$f(T(\eta), \eta) = \left(\eta, x_0-\int_{t_0}^{t} X^{-1}(\xi)b(\xi)\operatorname{sgn}(b^T(\xi)X^{-1}(\xi)^T\eta)\,d\xi\right) = 0$$

and $X^{-1}(t)$ is the adjoint fundamental matrix solution of $F(t)$. The maximization of T is usually carried out iteratively by a steepest descent method on η. This paper represents a careful theoretical and experimental exploration of the geometrical aspects of the steepest descent method on η. It concludes that convergence can be improved by carrying out the descent in a transformed ρ-space which is related to η by a nonsingular linear transformation P. Methods for computing P are discussed.

Y.-C. Ho (Cambridge, Mass.)

Petrov, V. A.; Skvorcov, G. V. 5677

A problem on the analytic construction of controllers. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1399–1403.

Authors' summary: "Based on Pontrjagin's maximum principle, a problem of synthesis is solved for a relay controller providing a second-order system optimality according to energy consumption and control rate."

Sirazetdinov, T. K. 5678

On the theory of optimal processes with distributed parameters. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 463–472.

Author's summary: "A maximum principle is established as a necessary condition for optimality of control processes described by quasi-linear partial differential equations with several independent variables. In the case of a linear equation, the maximum principle is also a sufficient condition."

W. H. Fleming (Providence, R.I.)

Volin, Ju. M.; Ostrovskiĭ, G. M. 5679

On an optimal problem. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1414–1420.

Authors' summary: "Calculation of optimum conditions for a class of chemical-technological processes described by partial differential equations is considered."

Živogljadov, V. P. 5680

Application of statistical solution theory to control problems with indirect index. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1451–1461.

Author's summary: "The statistical solution theory is applied to the synthesis of optimal control systems whose parameters can be measured in definite time intervals so that the input control must be used. The obtained results are applied to Markov plants and delay systems. Some

examples of the synthesis of discrete and continuous control systems are described."

Bacon, Glenn C. 5681

The decomposition of stochastic automata.

Information and Control 7 (1964), 320–339.

Author's summary: "Finite-state stochastic sequential systems which are interconnections of two or more component systems exhibit a special structural property in their transition matrices as a consequence of the statistical independence of the next states of the component systems given the present states and the input to the interconnection. Along with the concept of a 'lumpable' stochastic matrix, this structural property is of central importance to the decomposition theory presented. These ideas allow a generalization to the stochastic case of the definitions used by Hartmanis [Information and Control **5** (1962), 25–43; MR **26** #2335] in his study of the decomposition of conventional switching circuits. With these definitions we are able to prove decomposition theorems for stochastic automata which reduce to those of Hartmanis in the deterministic case." *J. Hartmanis* (Schenectady, N.Y.)

Kim, Wan Hee; Chien, Robert Tien-Wen 5682

★Topological analysis and synthesis of communication networks.

Columbia University Press, New York-London, 1962. x+310 *pp.* $11.50.

Part I: Topological analysis of electrical networks. Fundamentals of the theory of linear graphs (Chapter 1); Analysis of the ordinary two-port networks (Chapter 2); Linear active multipoles. Part II: Flow-graph techniques for the solution of linear and sampled-data systems. Topological properties of signal-flow graphs (Chapter 1); Flow-graph analysis of sampled-data systems (Chapter 2); Flow-graph analysis of multirate sampled-data systems (Chapter 3). Part III: Analysis and synthesis of linear N-port networks. Formulation of N-port networks (Chapter 1); Analytic properties of Y- and Z-matrices (Chapter 2); Realization of a Y-matrix with $(n+1)$ nodes (Chapter 3); Generalized realization of a Y- and Z-matrix (Chapter 4). Part IV: Synthesis of single-contact switching networks and realization of loop and cut-set matrices. Fundamentals of the theory of contact networks (Chapter 1); Realization of loop and cut-set matrices. Part V: Analysis and synthesis of communication nets. Oriented communication nets (Chapter 1); Nonoriented communication nets (Chapter 2); Further discussion on communication nets (Chapter 3).

Koršunov, A. D. 5683

Lower bounds of complexity for contact networks which realize pairwise orthogonal functions of a Boolean algebra. (Russian)

Diskret. Analiz. No. 2 (1964), 42–47.

In this paper the number of contacts in a switching circuit containing transfer contacts only and realising a number k of pairwise orthogonal Boolean functions between a unique input terminal and k output terminals is found to be not less than $2k-2$. Application of this theorem shows that a tree circuit turns out to be one of such networks with the number of contacts being the possible minimum. *I. Cederbaum* (Tel-Aviv)

Kurki-Suonio, Reino 5684

On some sets of formal grammars.

Ann. Acad. Sci. Fenn. Ser. A I No. 349 (1964), 31 *pp.*

A presentation of some basic facts about regular sets and context-free languages is given. This includes characterization by finite-state automata and pushdown automata, respectively. The pushdown automaton discussed is a one-state device which accepts a word if the pushdown word at the end of the computation is an element of a pre-assigned finite set. No new results appear. *S. Ginsburg* (Van Nuys, Calif.)

Nečiporuk, É. I. 5685

On the complexity of networks in certain bases containing non-trivial elements with zero weights. (Russian)

Problemy Kibernet. No. 8 (1962), 123–160.

The author studies the problem of estimating the complexity, or cost, of circuits realizing Boolean functions of n variables. Various cases of this problem are distinguished according to the assumptions made concerning the class of admissible circuits, the basis from which the circuit elements are chosen, and the weights assigned to the basis elements. In the cases considered, the basis consists of a set E of elements of positive weight and a set Z of elements of weight zero. This corresponds to the practical problem of synthesizing circuits using minimal numbers of elements of certain types, while elements of other types may be used in unlimited number. Let $L(C)$ be the sum of the weights of the basis elements in the circuit C. If f is a Boolean function, let $L(f)=\inf L(C)$ for circuits C realizing f. The "Shannon function" $L(n)$ is defined to be $\max L(f)$ for Boolean functions f of n arguments. In the case where the admissible circuits are those called superpositions and the basis consists of elements of weight 0 realizing disjunction and conjunction and an element of weight 1 realizing inversion, exact expressions for $L(f)$ of the order of n are obtained. For certain other bases with non-empty set Z, asymptotic expressions for $L(n)$ are found. These have the form $A\cdot 2^n/n$ for superpositions, and the form $A\cdot 2^{(n/2)}$ for circuits of arbitrary topology. The author also obtains improvements in the lower and upper bounds for the minimal number of contacts in contact-rectifying circuits. *G. N. Raney* (Storrs, Conn.)

Ofman, Yu. [Ofman, Ju.] 5686

On the algorithmic complexity of discrete functions.

Dokl. Akad. Nauk SSSR **145** (1962), 48–51 (*Russian*); *translated as Soviet Physics Dokl.* 7 (1963), 589–591.

This paper studies by means of finite automata the complexity of discrete functions $d: D^k \to D^n$, where D^k is the k-dimensional vector space over the field of two elements. The complexity of d is defined by the minimal elements of the set of pairs (N, T), where N is the memory (or stages) required in an automaton which computes d, and T is the computation time of this automaton. (The author has assumed that the next state of a memory element can be only a function of the present states of two other memory elements.) A number of results are concerned with the rate of growth of N and T as the size of the problem grows. For example, it is shown that if $k=2m$, $n=m+1$ and d is the sum of two binary numbers of m digits, then d can be realized by an automaton with $N\sim m$ and $T\sim \log_2 m$. *J. Hartmanis* (Schenectady, N.Y.)

Pfeiffer, Paul E. 5687

★**Sets, events, and switching.**

McGraw-Hill Book Co., New York-Toronto-London, 1964. xiii+131 *pp.* $4.95.

This is an introductory book, written for undergraduate engineering students, although one would hope that mathematics majors would be exposed to it also. The author has very nicely combined material on sets, functions, Boolean algebra, and design of switching networks, so that a student may see the relationships between these areas without having to deduce it for himself. It is written in a very readable, yet not condescending, style. Each chapter is followed by a good selection of problems. On the slightly negative side, one notes that the definition of "minterm" appears on page 37, but this is not included in the index. And the inverse map f^{-1} of f is called the inverse function even if it is not a function. This book is certainly recommended for the audience for which it was written. *B. A. Galler* (Ann Arbor, Mich.)

Popkov, Ju. S. 5688

The influence of intense noise on periodic regimes in extremal sampled-data systems with independent search. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1462–1471.

Author's summary: "Error effect on periodic states in sampled-data extremal systems with independent search is analysed, based on the methods of statistic linearization and on the theory of Markov processes. Taking into account the frequency characteristic of the sampled-data extremal system with an error and correlation time less than the sampler repeating period, the author determines the error intensity which results in periodic state breakage. Data of theoretical and experimental study of a sampled-data extremal system with a second-order object and of a similar relay extremal system are described."

★**Logic, automata and algorithms [Логика. Автоматы. Алгоритмы].**

Gosudarstv. Izdat. Fiz.-Mat. Lit., Moscow, 1963. 556 *pp.* 1.45 *r.*

Bon manuel introductif (on y trouvera une présentation simple en général des notions de base dans les domaines suivants: automates finis (théorie et réalisation technique), réseaux neuroniques, algorithmes, fonctions récursives, machines de Turing), ce livre, selon les auteurs eux-mêmes, est destiné à exposer simplement aux ingénieurs la théorie, et aux mathématiciens la traduction technique de cette théorie. *F. Dejean* (Paris)

Blank, A. M. 5691

Expediency of automata. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1472–1483.

Author's summary: "A mathematical model is proposed for notions of 'expediency' and 'learning'. Peculiarities of finite automata possessing the expediency and the learning for an expediency partial criterion and peculiarities of functions producing expedient and learned finite automata are considered."

Černý, Ján 5692

A remark on homogeneous experiments with finite automata. (Slovak. English summary)

Mat.-Fyz. Časopis Sloven. Akad. Vied **14** (1964), 208–216.

Author's summary: "Some papers [e.g., E. F. Moore, *Automata studies*, pp. 129–153, Princeton Univ. Press, Princeton, N.J., 1956; MR **17**, 1140; S. Ginsburg, J. Assoc. Comput. Mach. **5** (1958), 266–280; MR **22** #10882] are concerned with the question whether there exists, for a given sequential machine, a homogeneous experiment which would bring it into a uniquely determined state, not depending on the initial state of the machine. The problem was solved for Moore's machines with distinguishable states. In the present paper the corresponding problem is treated for autonomous automata (i.e., without output). Necessary and sufficient conditions for the existence of such experiments are stated and estimates of their minimal length are established."

Dobrovidov, A. V.; Stratonovič, R. L. 5693

On the design of optimal automata functioning in random media. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1433–1441.

Authors' summary: "The synthesis of the automaton interacting in the optimal way with a random medium is considered, the sequence of the medium states being a Markov chain. Recurrent transformation of a posteriori probabilities is used. The quality of the optimum automaton operation is analysed and the automaton operation is compared with the linear policy [M. L. Cetlin, Dokl. Akad. Nauk SSSR **139** (1961), 830–833; MR **24** #B480]."

Dušskiĭ, V. A. 5694

Characteristic experiments with automata. (Russian)

Problemy Kibernet. No. 11 (1964), 257–262.

A simple experiment of length k for an automaton is an input word of k letters. A multiple experiment is an ordered n-tuple of simple experiments, and one such that consists of all simple experiments of length k is said to be complete of length k. An experiment $\bar{p}$ is characteristic for an automaton A if an automaton B is equivalent to A whenever $\bar{p}$ fails to distinguish them. It is shown that any automaton with n states that has a complete characteristic experiment has one of length n^2+n-1, and that for any

automaton A with more than one letter in its input and output languages and any simple experiment p, there is an automaton B, distinct from A, that p fails to distinguish from A. *E. J. Cogan* (Bronxville, N.Y.)

Even, Shimon 5695

Test for synchronizability of finite automata and variable length codes.

IEEE Trans. Information Theory IT-10 (1964), 185–189.

Author's summary: "A finite automaton is called synchronizable of Nth order if the knowledge of the last N outputs suffices to determine the state of the automaton at one time during the last N outputs (including the initial and the final states). In an analogous manner synchronizability of Nth order is defined for variable length codes. The paper describes a test for synchronizability on a more general model, the coding graphs, and shows that finite automata and variable length codes are special cases of it."

Schutzenberger, M. P. 5696

Certain elementary families of automata.

Proc. Sympos. Math. Theory of Automata (New York, 1962), pp. 139–153. *Polytechnic Press of Polytechnic Inst. of Brooklyn, Brooklyn, New York*, 1963.

Author's summary: "We attempt to relate the difficulty of the decision problem of certain algorithms (automata) with the underlying algebraic structure. In particular, we discuss the connection between 'push-down storage' and 'extension of a free group by a finite monoid'."

A. P. Ershov (Novosibirsk)

Marcinkiewicz, Józef 5697

★**Collected papers.**

Edited by Antoni Zygmund. With the collaboration of Stanisław Łojasiewicz, Julian Musielak, Kazimierz Urbanik and Antoni Wiweger. Instytut Matematyczny Polskiej Akademii Nauk.

Państwowe Wydawnictwo Naukowe, Warsaw, 1964. viii + 673 *pp*. (3 *plates*)

This volume contains a biography and an analysis of Marcinkiewicz's work by Zygmund; a supplementary bibliography of papers related to Marcinkiewicz's work; and the text of Marcinkiewicz's 55 papers (the two that originally appeared in Polish have been translated into English). Marcinkiewicz contributed new ideas to several fields, and it seems that their potentialities have not even yet been fully explored. A number of open problems are mentioned in Zygmund's analysis.

Stoïlow, S. 5698

★**Œuvre mathématique.**

Éditions de l'Académie de la République Populaire Roumaine, Bucharest, 1964. xix + 416 *pp*. *Lei* 30.00.

This volume contains a reprinting of 65 papers of Stoïlow, ranging from his dissertation [Gauthier-Villars, Paris, 1916] to a brief abstract of his lecture at the Fifth Austrian Congress of Mathematicians at Innsbruck in 1960. The volume is particularly valuable for the inclusion of many relatively inaccessible papers published between 1940 and 1946. In addition to the Foreword by M. Nicolescu, there is a brief account of Stoïlow's work by C. Andreian Cazacu.

Matematička Biblioteka 22. *Zavod za Izdavanje Udžbenika, Belgrade*, 1962. 192 *pp*. 600 *Dinara*.

This volume consists primarily of a collection of expository articles on various topics in mathematics. The articles and authors are as follows: Cyclic functional equations (pp. 5–23) by D. S. Mitrinović and D. Ž. Đoković; Application of functional analysis to the theory of partial differential equations (pp. 25–36) by S. Kurepa; Some applications of differential inequalities (pp. 37–45) by M. Bertolino; On some inequalities of orthogonal polynomials (pp. 47–53) by B. S. Popov; Three remarks on integration of differential equations by means of differentiation (pp. 55–59) by I. A. Šapkarev; Application of the calculus of residues to the calculation of some definite integrals (pp. 61–70) by D. Dimitrovski; The Staudt-Clausen Theorem (pp. 71–79) by K. Milošević-Rakočević; On nonsquare matrices (pp. 81–86) by M. Stojaković; On curves (pp. 87–96) by P. Papić; On the dimension of geometric constructions (pp. 97–104) by S. Mardešić; On polygons (pp. 105–128) by M. Jorgović; Convex bodies (pp. 129–141) by V. Devidé; On non-Euclidean Geometry (pp. 143–168) by D. Blanuša; On an analogue of Euler's rule (pp. 169–176) by S. Fempl; Several examples of the determination of the orbit of a point by means of vectors (pp. 177–180) by S. V. Pavlović; A direct proof of Steiner's theorem for an equilateral triangle (pp. 181–182) by V. Janeskoski. The papers are in Serbo-Croatian.

J. V. Wehausen (Berkeley, Calif.)

Mitrinović, D. S. (Editor) 5702

★**Zbornik matematičkih problema sa prilozima i numeričkim tablicama. I [Collection of mathematical problems with appendices and numerical tables. I].**

Third edition.

Zavod za Izdavanje Udžbenika, Belgrade, 1962. xvi + 503 *pp*. 1300 *Dinara*.

This collection of problems has been prepared by D. S. Mitrinović with the collaboration of D. D. Adamović, D. Ž. Đoković, Z. R. Popstojanović, and S. B. Prešić. It is divided into the following chapters, with the numbers in parenthesis giving the number of problems: Algebra (226); Theory of numbers (65); Analytic geometry and vectors (36); Differential calculus (128); Integral calculus (122); Sequences and series (97); Inequalities (256); Problems from various fields (248) (determinants, matrices, curvilinear and multiple integrals, differential and functional equations, special functions, real functions of a single variable, complex numbers and functions); Appendices and numerical tables. The problems have been gathered from many sources including journals such as the Amer. Math. Monthly, Math. Gazette, Mat. Tidsskr., etc., and various mathematical prize contests. They are well-selected, and the collection should prove to be very useful.

HISTORY AND BIOGRAPHY

Carruccio, Ettore 5704

Considerazioni sul significato di alcuni termini fondamentali degli Elementi di Euclide.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 226–234.

The author suggests that in Euclid's *Elements* the term "*εὐθεῖα*" stands for "line segment" and not for "indefinite line", and similarly "*ἐπίπεδος ἐπιφάνεια*" for "plane region" (superficie piana limitata). The term "*ἴσος*" always means "equal in extension" (hence "equivalent") and not "superimposable by motion". There remains, however, a certain ambiguity in Euclid's use of "*κύκλος*" and "*περιφέρεια*", circle and circumference.

D. J. Struik (Belmont, Mass.)

Szabó, Árpád 5705

The transformation of mathematics into deductive science and the beginnings of its foundation on definitions and axioms. II.

Scripta Math. **27**, 113–139 (1964).

In diesem zweiten Teil [für den ersten Teil siehe dieselben Scripta **27** (1964), 27–48A; MR **29** #1120] geht der Verfasser auf Einzelheiten mathematischer Natur ein. Die Pythagoreer räumen der Geometrie als einer Art von Erfahrungswissenschaft geringere Bedeutung ein als der Arithmetik. Die Definition der Einheit als das Unteilbare verrät den Einfluss des Parmenides und findet ihr Gegenstück in der Geometrie bei der Definition des Punktes. Terminologie und Bedeutung des Teilungsproblems hat zunächst mit der Halbierung zu tun und steht in Beziehung zu den Begriffen gerade und ungerade. Das Axiom vom Ganzen und vom Teil hängt zusammen mit Zenos Paradoxien, die wohl im Sinne der modernen Mengenlehre gedeutet werden sollten und alsdann durchaus sinnvoll sind. Die Pythagoreische Zahlenlehre steht nicht im Gegensatz zur Auffassung der Eleaten, ist vielmehr als eine Weiterbildung anzusehen.

★Archimedes in the Middle Ages. Vol. I: The Arabo-Latin tradition.

The University of Wisconsin Publications in Medieval Science, No. 6.

The University of Wisconsin Press, Madison, Wis., 1964. xxix + 720 *pp.* $12.00.

Einzelheiten über das Bekanntwerden Archimedischer Schriften im lateinischen Mittelalter hat der Verfasser schon in zahlreichen früheren Veröffentlichungen mitgeteilt. Hier haben wir den ersten Band einer sehr verdienstvollen Gesamtdarstellung vor uns, deren Ziel es ist, die zum Teil noch unedierten Ms. mit bibliographischer Einleitung, im lateinischen Wortlaut mit englicher Übersetzung und sorgfältigen sachlichen Erläuterungen festzuhalten. Hauptthema ist die Kreismessung, die in zwei frühesten Übersetzungen nach der arabischen Fassung des Thâbit ibn Qurra (um 890) vorliegen, die eine wohl von Plato v. Tivoli (um 1140, Barcelona, unvollständig), die andere von Gerhard v. Cremona (um 1170, Toledo, Vergleich mit der arabischen Revision des aṭ-Ṭûsî, um 1250). Anschließend erscheinen drei stark von Gerhard beeinflußte Fassungen, dann drei weitere mit selbständigen Einschüben und Zusätzen.

Die Kreismessung ist auch in einer Paraphrase der Banû Mûsâ (um 850) enthalten, die ebenfalls in der Revision des aṭ-Ṭûsî vorliegt und wiederum von Gerhard übersetzt wurde. Sie enthält außerdem die "Heronische" Dreiecksformel, der genauere Ausführungen in einem Anhang gewidmet sind, und Stücke aus *De sphaera et cylindro* einschließlich der Kommentare des Eutokios (Einschiebung zweier geometrischer Mittel, Dreiteilung des Winkels, Näheres wieder im Anhang). Etwas anderen Aufbau zeigen die Übertragung des sogenannten Pseudo-Bradwardine (etwa 14. Jh.) und die *Quaestio* des Albert v. Sachsen (um 1360?).

Noch vor der Übersetzung Archimedischer Schriften durch Moerbeke (1269) findet sich zunächst die Zusammenstellung einiger Hauptsätze aus *De sphaera et cylindro* und dann ein umfangreiches Ms. des Joh. de Tinemue des Titels *De curvis superficiebus* mit wichtigen späteren Zusätzen. In sechs Anhängen erscheinen weitere Quadraturen, die nicht aus Archimedes stammen (Jordanus, Pseudo-Campanus), die "Möndchenquadratur" (vielleicht lateinisch aus dem Griechischen von Grosseteste, um 1240) und lateinische Archimedes-Zitate aus dem 12. bis 15. Jh.

Das hervorragend ausgestattete Werk ist mit einer eingehenden Bibliographie, mit einem umfangreichen und terminologisch besonders wichtigen Wortverzeichnis, mit einem Verzeichnis der zitierten Sätze aus Euklids Elementen, mit einer Übersicht über die angezogenen lateinischen Ms. und mit einem umfangreichen Namen- und Sachverzeichnis versehen. Schon aus dem bisherigen läßt sich Wichtiges über das Wiederaufleben der Archimedischen Betrachtungsweise erkennen. Weiteres erwarten wir von der Fortsetzung des Werkes, der wir mit größtem Interesse entgegensehen.

Meigne, Maurice 5710
★Recherches sur une logique de la pensée créatrice en mathématiques.
Préface de Georges Bouligand.
Librairie Scientifique et Technique, Albert Blanchard, Paris, 1964. 132 *pp.* 18.00 *F.*
Der Verfasser entwickelt die Idee einer schöpferischen Logik der Mathematik. Gegenüber formalisierten Theorien wird der Einwand grundsätzlicher Unvollkommenheit erhoben, da der Sinn einer mathematischen Theorie nicht vollständig formal erfaßbar sei und die mathematische Forschung auf unformalisierbaren schöpferischen Intuitionen beruhe. Im Hinblick auf eine schöpferische Logik werden insbesondere Untersuchungen der Geometrie, Analysis und Gruppentheorie diskutiert. Die hierbei entwickelten Aspekte können nach Ansicht des Referenten zwar für heuristische Überlegungen und interpretative Vorstellungen von Bedeutung sein, betreffen aber nicht das besondere Anliegen der mathematischen Logik und Grundlagenforschung, mathematische Theorien in mathematisch exakter Weise zu untersuchen. Das Buch ist nicht frei von mathematischen Fehlern. So wird auf S. 29 die falsche Behauptung aufgestellt, daß die Menge der arithmetischen Ausdrücke (die etwa aus natürlichen Zahlen oder Zahlenvariablen und dem Additionszeichen gebildet werden können) nicht abzählbar sei.
K. Schütte (Kiel)

Devidé, Vladimir 5711
★Matematička logika. Prvi 1: Klasična logika sudova [Mathematical logic. Part 1: The classical propositional logic].
Posebna Izdanja Matematičkog Instituta, Kniga 3.
Matematički Institut u Beogradu, Belgrade, 1964. 228 *pp.*
In the Serbo-Croatian mathematical literature there is no book on mathematical logic; this is, perhaps, the reason why the Mathematical Institute in Belgrade incorporated this textbook in its series "Special Editions", which is supposed to cover only monographs, large original papers, and mathematical tables. The book is written in Serbo-Croatian, it is dedicated to the Japanese people, and it has an English summary.

This is a first introduction to mathematical logic; the present first volume is concerned only with propositional calculus, and in some 220 pages covers about the same material as the first 44 pages of the book of Mendelson; however, there are no problems and exercises, but there is an original part enumerating all possible bases of the propositional calculus: the beginning reader will know that there exist exactly two one-member bases, 34 two-member bases (all are quoted), and 10 three-member bases (all are quoted, too).

Detailed contents: Chapter 1 (Introduction) explains "the most serious, deepest, and most difficult, but also most brilliant, crisis of mathematics", i.e., the antinomies. Chapter 2 (Propositional algebra) contains usual material about functors, truth-values, bases, duality, and electrical switching networks. All bases with one, two and three members are enumerated. Chapter 3 (Propositional algebras as Boolean structures) describes the elements of lattice theory and Boolean algebra. Chapter 4 (Propositional logic) uses a slightly different axiom-system from that of Hilbert and Bernays; other axiom-systems are also exhibited, and the equivalence with the author's system is shown for many of them. Chapter 5 (Some properties of axiom-systems for propositional logic) discusses consistency, completeness, non-categoricity, and similar topics.

The exposition is lengthy, enthusiastic, and annoying. However, with some effort, the reader can learn from this book the basic facts of the propositional calculus.

Enumerative quantifiers and predicate calculus.
Acta Math. Sinica **14** (1964), 218–230 (*Chinese*); *translated as Chinese Math.* **5** (1964), 239–253.

Singletary, Wilson E. 5714
Correction to "A complex of problems proposed by Post".
Bull. Amer. Math. Soc. **70** (1964), 826.

The author modifies the semi-Thue system σ and the propositional calculus $\mathfrak{P}_\sigma$ upon which the results in an earlier paper [same Bull. 70 (1964), 105–109; MR 28 #2040] depend. For σ, each word G_i and $\bar{G}_i$ is now required to have at least two letters. For $\mathfrak{P}_\sigma$, p_1 is replaced by $[p_1 \& p_3]$ and q_1 by $[q_1 \& q_2]$ throughout Axioms 3, 4 and 7; r_1 is replaced by $[r_1 \& r_3]$ in Axiom 7.

It is not known whether the original σ and $\mathfrak{P}_\sigma$ have the required properties. *G. F. Rose* (Pacific Palisades, Calif.)

Weinberger, Ota 5715

Théorie des propositions normatives. Quelques remarques au sujet de l'interprétation normative des systèmes K_1 et K_2 de M. Kalinowski. (Polish and Russian summaries)

Studia Logica 9 (1960), 7–25.

Skolem, Th. 5716

Studies on the axiom of comprehension.

Notre Dame J. Formal Logic 4 (1963), 162–170.

The author considers three forms of the axiom of comprehension.

(1) $(z_1)\cdots(z_n)(\mathsf{E}y)(x) \quad (x \in y \Leftrightarrow \varphi(x, z_1, \cdots, z_n)),$

(2) $(z_1)\cdots(z_m)(\mathsf{E}y)(x)$

$$\Bigl(x \in y \Leftrightarrow \prod_{u_1}\cdots\prod_{u_n} \varphi(x, z_1, \cdots, z_m, u_1, \cdots, u_n)\Bigr),$$

(3) $(\mathsf{E}y)(x) \quad \Bigl(x \in y \Leftrightarrow \prod_{u_1}\cdots\prod_{u_n} \varphi(x, u_1, \cdots, u_n)\Bigr).$

In (1), φ is either a propositional constant or is built up from atomic expressions $u \in v$ by negation, conjunction, and disjunction, and there are no further variables in φ other than $x, z_1, \cdots, z_n$. In (2), φ also contains the variables $u_1, \cdots, u_n$ and each $\prod_{u_i}$ is either a universal quantifier or existential quantifier with respect to u_i. In (3), φ contains no variables other than $x, u_1, \cdots, u_n$. In a previous paper [same J. 1 (1960), 13–22; MR 26 #4890], the author constructed a denumerable model M satisfying (1) for all φ without negation. Now he shows that M satisfies (2) for all φ without negation. In the cited paper it was indicated that there is no finite model for which (1) holds for negation-free φ. Here the author exhibits a five-element model satisfying (3) for all negation-free φ. Next, a denumerable model is given for which (1) holds for all φ in which no atomic formula $u \in u$ or $u \bar{\in} u$ occurs. Then the author gives a simpler proof of an earlier result of his, namely, the construction of a denumerable model satisfying (1) in 3-valued logic. All the models discussed also satisfy the axiom of extensionality. Finally, two number-theoretic models are exhibited which satisfy certain weak subtheories of Zermelo-Fraenkel-Skolem set theory. *E. Mendelson* (Flushing, N.Y.)

Vasil'ev, Ju. L. 5717

Comparison of the complexity of terminal and minimal disjunctive normal forms. (Russian)

Problemy Kibernet. No. 10 (1963), 5–61.

A disjunctive normal form (d.n.f.) is said to be terminal if removal of any disjunct or any conjunct within a disjunct leads to a non-equivalent d.n.f. If T is a d.n.f., let $Z(T)$ be the number of occurrences of letters in T, and let $I(T)$ be the number of disjuncts in T. If f is a given truth function, and $\mathfrak{T}(f)$ is the set of all terminal d.n.f.'s representing f, let $R(f) = \max Z(T_1)/Z(T_2)$ and $Y(f) = \max I(T_1)/I(T_2)$ for all T_1, T_2 in $\mathfrak{T}(f)$. If $p^{(n)}$ denotes the set of all truth functions of n variables, let $R(n) = \max R(f)$ and $Y(n) = \max Y(f)$ for all functions f in $p^{(n)}$. The author proves that $2^{n-8\sqrt{n}} \le Y(n) \le 2^{n-\log n}$ and $2^{n-8\sqrt{n}} \le R(n) \le 2^n$. Various additional results and applications are given. *E. Mendelson* (Flushing, N.Y.)

Rasiowa, H. 5718

On modal theories.

Acta Philos. Fenn. Fasc. 16 (1963), 201–214.

The author collects in this paper her results (and those of R. Sikorski) concerning the metatheory of pure and applied formal theories of modal logic. The language L of such modal theories is that of first-order logic with one additional unary propositional connective, necessity I. The basic semantical notions are introduced roughly as follows. Let J be a nonempty set, and let $\mathfrak{A}$ be a complete topological Boolean algebra. Let $\mathfrak{M}$ be a mapping associating with each m-place predicate of L a function from J^m into $\mathfrak{A}$. The mapping $\mathfrak{M}$ is extended to L in the obvious way by associating with the logical operations the corresponding Boolean operations in $\mathfrak{A}$; the interior operation of $\mathfrak{A}$ is associated with I, and g.l.b. and l.u.b. are associated with the quantifiers. $\mathfrak{M}$ is called a realization of L in I and $\mathfrak{A}$. An assignment v of elements of J to the free variables $x_1, \cdots, x_n$ occurring in a formula α of L is said to satisfy α in $\mathfrak{M}$ if $\mathfrak{M}$ maps α onto a function $\alpha_{\mathfrak{M}}(x_1, \cdots, x_n)$ for which $\alpha_{\mathfrak{M}}(vx_1, \cdots, vx_n)$ is the unit element of $\mathfrak{A}$. A wealth of interesting material is covered in survey fashion. The main results are generalizations of the fundamental notions and results concerning first-order theories and intuitionistic logic to modal theories. *E. Engeler* (Minneapolis, Minn.)

Büchi, J. Richard 5719

Turing-machines and the Entscheidungsproblem.

Math. Ann. 148 (1962), 201–213.

This paper provides (as the author remarks) the first really elegant proof of the unsolvability of the decision problem for q.t. (quantification theory—without identity). It also contains an extremely short proof of an improved version of Trachtenbrot's theorem (that the non-satisfiable sentences cannot be recursively separated from those satisfiable in a finite domain). The improvement obtained by the author is the addition "not even if only sentences of the form $E \& AEA$ are considered". This, of course, implies that the set of finitely satisfiable sentences is not recursive, again even if only sentences of the form $E \& AEA$ are considered.

The reviewer urges that this paper be regarded as the henceforth standard proof of Church's and Trachtenbrot's theorems. The problems Büchi mentions at the end of the paper (the "unrestricted domino problem" and the problem "T2") have been solved by students of Wang, but the solutions are not yet in print. *H. Putnam* (Cambridge, Mass.)

Pour-El, Marian Boykan; Howard, William A. 5720

A structural criterion for recursive enumeration without repetition.

Z. Math. Logik Grundlagen Math. 10 (1964), 105–114.

The authors generalize the result that the recursively enumerable sets are recursively enumerable without repetition (Friedberg) in the following way: any recursively enumerable class F with a partial recursive height function is recursively enumerable without repetition. By a height function is meant a function h defined on the finite subsets of members of F with the properties: (1) monotonicity: if $A \subseteq B$, then $h(A) \leq h(B)$; (2) convergence (the authors call this "the ascending chain condition"): if $A_1 \subseteq A_2 \subseteq A_3 \subseteq \cdots$ is an ascending sequence of finite subsets of a fixed member of F, then the associated sequence of heights $h(A_1)$, $h(A_2)$, $\cdots$ eventually becomes constant; (3) unboundedness: for every finite subset A of a member of F, there exists a finite subset B, not necessarily of the same member of F, such that $A \subset B$, $h(A) < h(B)$.

The proof is by a complicated "priority" argument. In following the proof, the following remarks may be of help (the authors give little motivation). The first two conditions enable one to associate a "height" with each member of F, namely, if $S \in F$ is finite, "height" $(S) = h(S)$; if $S \in F$ is infinite, "height" $(S) = \max(h(S_i))$, S_i a finite subset of S. It can easily be proved from (1) and (2) that this maximum exists. Note that the "height" of $S \in F$ can be successively approximated from below by taking finite subsets, and that the approximations must eventually all be correct. The condition (3) implies that a finite subset of any member of F is also a finite subset of some member of F with "height" as great as one pleases. These facts allow one to modify Friedberg's original proof to obtain the theorem.

Several corollaries are obtained by the authors, including Friedberg's original result.

H. Putnam (Cambridge, Mass.)

Mostowski, A. 5721

On invariant, dual invariant and absolute formulas.
Rozprawy Mat. **29** (1962), 38 *pp.*

This paper is about the simple theory of types T_ω. A model $\mathscr{M}$ of T_ω consists of a pair $\langle R, S\rangle$, where $R = (R_0, R_1, \cdots)$ is a sequence of sets and $S = (S_0, S_1, \cdots)$ is a sequence of binary relations S_i between elements of R_i and R_{i+1}. The standard model $\mathrm{St}(R_0)$ is the model in which each R_{i+1} is the power set of R_i and each S_i is the ϵ relation between R_i and R_{i+1}. Let N be a ternary relation. We say that n represents N in a model $\mathscr{M}$ if (1) the set R_0 of individuals of $\mathscr{M}$ contains the field of N, (2) n is in R_5 and is a set of "ordered triples" of elements of R_0 in the sense of $\mathscr{M}$, and (3) $N(x, y, z)$ holds if and only if the "ordered triple" (x, y, z) belongs to n in the sense of $\mathscr{M}$. Let K be a class of models and let Φ be a formula of T_ω with a single free variable of order 5. We say that Φ is absolute with respect to K if for every $\mathscr{M}$ in K and every ternary relation N over R_0 which is represented in $\mathscr{M}$ by an element n, the conditions (a) n satisfies Φ in $\mathscr{M}$ and (b) N satisfies Φ in $\mathrm{St}(R_0)$ are equivalent. Φ is said to be invariant with respect to K if (a) implies (b), and dual invariant with respect to K if (b) implies (a). The main theorems are necessary conditions, in terms of first-order model theory, for a formula Φ of T_ω to be absolute, invariant, or dual invariant. We state two of the main results below. Let Z be a set of closed formulas of T_ω which are true in every standard model with infinitely many individuals. Let K be the set of all models $\mathscr{M}$ in which all formulas of Z are true. Theorem: If Φ is absolute with respect to K, then there is a first-order closed formula $S(M, N)$ with a unary predicate variable M and a ternary predicate variable N such that, for all infinite sets M and ternary relations N over M, N satisfies Φ in $\mathrm{St}(M)$ if and only if $S(M, N)$ holds. The author attributes to Scott the remark that the above theorem can also be proved using a result of the reviewer [Nederl. Akad. Wetensch. Proc. Ser. A **64** (1961), 477–495; MR **25** #3816] concerning ultraproducts. In the next theorem we assume further that Z is recursively enumerable and every formula in Z holds in all standard models. Theorem: If Φ is invariant with respect to K, then there is a first-order formula $F(M, N, Q_1, \cdots, Q_k)$ such that for all M and $N \subset M^3$, N satisfies Φ in $\mathrm{St}(M)$ if and only if there exists a model $\langle I, M, N, Q_1, \cdots, Q_k\rangle$ of F such that $I - M$ is infinite. There is also a similar result for dual invariant formulas Φ. The proofs are based upon formalizing in first-order logic the semantics for T_ω, and considering the models of the first-order theory so obtained. The author also states, proves, and uses a reformulation of a joint result of Ehrenfeucht and Mostowski [Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **9** (1961), 369–373; MR **26** #6043] concerning compact spaces of models.

H. J. Keisler (Madison, Wis.)

van Rootselaar, B. 5722

Algebraische Kennzeichnung freier Wortarithmetiken.
Compositio Math. **15**, 156–168 (1963).

An algebraic characterization is given of the free arithmetics of words studied by Vučković [Acad. Serbe Sci. Publ. Inst. Math. **14** (1960), 9–60; MR **22** #A3087]. It is used to establish some new properties of these arithmetics. A structure which is an additive semi-group with identity and right cancellation, is a multiplicative semi-group with identity, satisfies $0 \cdot x = 0$ and the left distributive law, and has no proper divisors of zero is called a near semi-ring ("Fasthalbring"). Let H be a near semi-ring with multiplicative center Z. Let ALE be the set of near semi-rings satisfying the following three conditions. Condition A: there is a mapping $\alpha: H \to Z$ satisfying (A1) $\alpha(x+y) = \alpha(y)$ if $y \neq 0$; (A2) $\alpha(x \cdot y) = \alpha(x) \cdot \alpha(y)$; (A3) $\alpha(c) = c$ if $c \in Z$; (A4) $\alpha(x) = 0$ implies $x = 0$. Condition L: for all $x \in H$, $y + \alpha(x) = x$ is solvable in H. Since by additive right cancellation the solution y is unique, define $\beta: H \to H$ by $\beta(x) = y$. Condition E: for all $x \in H$ there is a natural number i such that $\beta^{(i)}(x) = 0$. In what follows let $H \in$ ALE and Z be its multiplicative center and let $V(n)$ $[V(\omega)]$ be the free arithmetic of words on n letters [on a countably infinite alphabet]. It is shown that for all H, if Z is a finite cyclic group of order n, $n > 1$, then H is isomorphic to $V(n)$ and that if Z is an infinite cyclic semi-group with identity, then H is isomorphic to $V(\omega)$. (Here, $+$ and $\cdot$ of the near semi-ring are identified with the first addition and multiplication of the arithmetic upon which the other additions and multiplications are dependent.) Noting that the additive semi-group generated by the elements of Z is just H, define

$$\lambda xy\, x - y : H \times H \to H$$

by (1) if $x, y \in Z$, then $x - y = 0$ whenever $x = y$, $x - y = x$ otherwise, (2) if $x = x_k + x_{k-1} + \cdots + x_1$ and $y = y_k + y_{k-1} + \cdots + y_1$ and $x, y \in H$, then $x - y = (x_k - y_k) + \cdots + (x_1 - y_1)$. For x, $y \in H$, define $x \leq y$ if and only if there exists

$t \in H$ such that $x+t=y$. Then under the assumption that the cancellation law holds in Z, the following are shown to hold in H: (a) the cancellation law, (b) $w\cdot(x-y)=w\cdot x-w\cdot y$, and (c) if $w\neq 0$ and $w\cdot x\leq w\cdot y$, then $x\leq y$. For both $V(n)$ and $V(\omega)$ the multiplicative centers consist of the empty word together with the letters of the alphabet, and in these centers cancellation holds. Thus (a), (b), and (c) hold for $V(n)$ and $V(\omega)$.

Nerode, A. 5723

A decision method for p-adic integral zeros of diophantine equations.

Bull. Amer. Math. Soc. **69** (1963), 513–517.

This paper gives a simple decision method for p-adic integral zeros of Diophantine equations. Since there is already a disproof procedure (show that f has no zeros mod p^n for some n), the problem reduces to giving a proof procedure. This is given in two theorems: (1) that a polynomial f has a zero in p-adic integers if and only if f has a zero in p-adic algebraic integers; and (2) that $ZA(p)$, the p-adic algebraic integers, can be construed naturally as a computable domain, i.e., the operations of addition and multiplication can be performed effectively in $ZA(p)$. Then the required proof procedure is to simply exhibit a zero of f in $ZA(p)$ and verify that it is a zero by computation. (1) is proved by the author via elimination, while the author's proof of (2) depends essentially on the Hensel-Rychlik theorem.

H. Putnam (Cambridge, Mass.)

Robinson, Julia 5724

The undecidability of exponential Diophantine equations.

Logic, Methodology and Philosophy of Science (*Proc.* 1960 *Internat. Congr.*), *pp.* 12–13. *Stanford Univ. Press, Stanford, Calif.*, 1962.

This paper announces the negative solution (obtained by the author jointly with Martin Davis and the reviewer) of the decision problem for exponential Diophantine equations (i.e., Diophantine equations in which exponentiation as well as addition and multiplication is permitted). The result is a consequence of the stronger result, obtained by the above authors, that every recursively enumerable set or relation is exponential Diophantine. Indeed, it has even been shown by Davis, the reviewer and the author that every recursively enumerable set is just the set of non-negative values taken on by an exponential polynomial, and analysis of the proof shows that a function $f(x_1,\cdots,x_n,2^y)$ will always suffice, f a polynomial. Whether or not every recursively enumerable set is Diophantine is still unknown; indeed, it is not even known whether or not there is a polynomial f (in n variables) whose non-negative values are just the prime numbers.

Salomaa, Arto 5725

On the reducibility of events represented in automata.

Ann. Acad. Sci. Fenn. Ser. A I No. 353 (1964), 16 *pp.*

Let $\mathfrak{N}_k=\langle N_k,\lambda,r_1,\cdots,r_k\rangle$ be the free k-monadic algebra on one generator (N_k is the set of words on k symbols). A subset $\alpha\subseteq N_k$ is reducible if there exists a homomorphism $\rho:\mathfrak{N}_k\to\langle S,s_0,r_1',\cdots,r_k'\rangle$ and a subset $S'\subseteq S$ with $\mathrm{card}(S')<\mathrm{card}(\alpha)$ and $\rho^{-1}(S')=\alpha$. In the first section of the paper the author proves some properties of reducible sets. The second section is a study of "the representation theory of finite events".

J. W. Thatcher (Yorktown Heights, N.Y.)

Salomaa, Arto 5726

Axiom systems for regular expressions of finite automata.

Ann. Univ. Turku. Ser. A I No. 75 (1964), 29 *pp.*

For any regular expression α, $|\alpha|$ is the regular set denoted by α, and $\alpha=\beta$ is a valid equation if $|\alpha|=|\beta|$. The author considers the problem of axiomatizing the valid equations. Two deductive systems for equations are defined. Both $\vdash_1$ and $\vdash_2$ use the rules of equational deducibility and in addition: (1) If $\lambda\notin\beta$ and $\vdash_1\alpha=\beta\alpha\cup\gamma$ $[\vdash_1\alpha=\alpha\beta\cup\gamma]$, then $\vdash_1\alpha=\beta^*\gamma$ $[\vdash_1\alpha=\gamma\beta^*]$; (2) If $\vdash_2\alpha=\alpha\cup\gamma\beta^n\delta$ for every $n\geq 0$, then $\vdash_2\alpha=\alpha\cup\gamma\beta^*\delta$. In these rules, α,β,γ and δ are arbitrary regular expressions. Because the author deals with regular expressions (as opposed to terms in $\cup$, $\cdot$, $*$, and variables over regular sets), the condition of the first rule can be stated syntactically. The author exhibits a simple axiom set which is complete with respect to the infinitistic system ($\vdash_2$). A complete axiomatization is given for the valid equations between expressions on one symbol using $\vdash_1$. The problem of obtaining a complete axiomatization of all valid equations using either equational deducibility or $\vdash_1$ remains open.

Flor, Peter 5730

Über die Wertmengen fastperiodischer Folgen.

Monatsh. Math. **67** (1963), 12–17.

The author shows that for any bounded, countable set of real numbers which is dense in itself there exists a one-to-one function k from the integers onto the set with the property of being an "almost periodic sequence", i.e., for every ε there is an n such that $a \equiv b \pmod n$ implies $|k(a) - k(b)| < \varepsilon$. The proof is by an explicit construction. A second construction shows that for any bounded countable set of real numbers there exists an almost periodic sequence whose range is the set and which assumes each value in the set periodically. The author points out that the conditions given are (trivially) necessary as well as sufficient. *H. Putnam* (Cambridge, Mass.)

Katona, Gy. 5731

Intersection theorems for systems of finite sets.

Acta Math. Acad. Sci. Hungar. **15** (1964), 329–337.

Let $k \leq m < \omega$, and let $M = \{0, 1, \cdots, m-1\}$. Find a set A such that (1) each $a \in A$ is a subset of M; (2) for all $a, b \in A$, $a \cap b$ has power at least k; (3) A has the maximum power among all sets satisfying conditions (1) and (2). Erdős, Chao Ko, and Radó [Quart. J. Math. Oxford Ser. (2) **12** (1961), 313–320; MR **25** #3839] conjectured that if $m+k$ is even, then the set A of all $a \subseteq M$ of power $|a| \geq \frac{1}{2}(m+k)$ has the desired properties (1), (2), (3). The author proves their conjecture. For the case that $m+k$ is odd he also obtains a solution: A is the set of all $a \subseteq M$ of power $|a| > \frac{1}{2}(m+k)$ together with all $a \subseteq M - \{m-1\}$ of power $|a| = \frac{1}{2}(m+k-1)$. *H. Bose Majumder, N. C. 5733b

Category of some sets related to the distance set of the Cantor set.

Bull. Calcutta Math. Soc. **55** (1963), 91–95.

Part I of #5733a appeared in Proc. Nat. Inst. Sci. India Part A **27** (1961), 289–294 [MR **24** #A2537]. Let C be the Cantor set on $[0, 1]$. Then for almost all d the set E_1 of pairs (x, y) of points of C such that $y - x = d$ has the cardinal number of the continuum. The author deduces a new proof of this from results in his earlier paper [Bull. Calcutta Math. Soc. **52** (1960), 1–13; MR **24** #A3444]. In the second paper he shows that E_1 is a residual set, and that the set E_2 of numbers d such that there are only finitely many pairs (x, y) of points of C with $y - x = d$ is of first category. *R. Slater, M. 5736

On a class of order-types generalizing ordinals.

Fund. Math. **54** (1964), 259–277.

The author investigates those order types for which the right half of every Dedekind cut has a first term. (Ordinals constitute the special case in which the type itself also has a first term.) He classifies these types in several ways, considers order-preserving maps between them, and presents an exhaustive discussion of their possible factorizations. *L. Gillman* (Rochester, N.Y.)

Sierpiński, W. 5737

Sur les ensembles raréfiés de nombres naturels.

Essays on the foundations of mathematics, pp. 300–303. *Magnes Press, Hebrew Univ., Jerusalem,* 1961.

Un ensemble E de nombres naturels est dit raréfié [muni de la propriété P] si, en le rangeant en ordre croissant $e_1 < e_2 < e_n$, l'on a

$$\lim_{n\to\infty} (e_{n+1} - e_n) = \infty \quad \left[\limsup_{n\to\infty} (e_{n+1} - e_n) = \infty\right].$$

La réunion d'un nombre fini d'ensembles raréfiés de nombres naturels est un ensemble raréfié (Théorème 1). La propriété P est plus faible que la propriété d'être raréfié. On ne sait pas si l'ensemble des nombres premiers est la réunion d'un nombre fini d'ensembles raréfiés. L'ensemble des nombres n^m ($n \in N$, $m \in N \setminus \{1\}$) possède la propriété P (Théorème 2) et d'après l'hypothèse de Pillai [Bull. Calcutta Math. Soc. **37** (1945), 15–20; MR 7, 145] est raréfié. *Đ. Kurepa* (Zagreb)

On a number of commuting transformations.

Comment. Math. Univ. Carolinae **4** (1963), 132–136.

Let X be an n-element set. A transformation is a mapping of X into itself. The author proves that any given transformation commutes with at least n different transformations. *G. Grätzer* (University Park, Pa.)

Dickmann, Maximo Alejandro 5739

König's theorem and the axiom of choice. (Spanish. English summary)

Rev. Un. Mat. Argentina **21**, 198–214 (1963).

L'auteur commence par établir un théorème en connexion directe avec le théorème connu de König de la théorie des nombres cardinaux; puis il démontre la proposition suivante: Si $\{A_\xi\}$, $\{B_\xi\}$, $\xi \in Z$, $Z \neq \varnothing$, sont deux familles d'ensembles satisfaisant aux conditions suivantes. (i) $\exists \alpha \in Z$, $\overline{\overline{B}}_\alpha \geqq \overline{\overline{Z-J}}+2$ avec $J=\{\xi \mid \xi \in Z,\ \overline{\overline{B}}_\xi \geqq 2\}$, (ii) $B_\xi \neq \varnothing$, $\forall \xi \in Z$, (iii) $\overline{\overline{J}} \geqq 2$, (iv) $\overline{\overline{A}}_\xi \leqq \overline{\overline{B}}_\xi$, $\forall \xi \in Z$, alors $\overline{\overline{\bigcup A_\xi}} \leqq \overline{\overline{\prod B_\xi}}$ $(\xi \in Z)$, et fait voir que ce théorème implique le précédent et aussi l'axiome du choix. Il prouve enfin que le théorème établi est le plus général relativement aux relations entre produits et sommes de familles arbitraires de nombres cardinaux. Toute une série d'exemples sont donnés, en vue de justifier l'indépendance et la nécessité des hypothèses. *A. Sade* (Marseille)

Gavrilov, G. P. 5740

On the cardinality of sets of closed classes of finite height in $P_{\aleph_0}$. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 503–506.

Let P be the set of all functions whose arguments and values lie in a fixed denumerable set. A subclass of P is said to be closed if it is closed under composition of functions. P is defined to be the only class of height 0. If M is any closed subclass of P, M is said to be of height $n+1$ if, for any function f in $P-M$, the closure under composition M_f of the class $M \cup \{f\}$ has height $\leq n$, and, for at least one such f, M_f has height n. Denote by $K(n)$ the collection of all classes of height n. This paper proves that $K(1)$ has cardinality 2^c. The author also states that, for any n, $K(n)$ can be shown to have cardinality 2^c. *E. Mendelson* (Flushing, N.Y.)

Kurepa, Đuro 5741

On universal ramified sets. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **18** (1963), 17–26.

Let α be a non-limit ordinal. Hausdorff [*Grundzüge der Mengenlehre*, Veit, Leipzig, 1914] constructed an $\aleph_\alpha$-universal totally ordered set of cardinal $\exp \aleph_{\alpha-1}$. J. B. Johnston [Proc. Amer. Math. Soc. 7 (1956), 507–514; MR **20** #3090] constructed an $\aleph_\alpha$-universal partially ordered set of cardinal $\exp \aleph_\alpha$. The present author constructs an $\aleph_\alpha$-universal ramified set of cardinal $\exp \aleph_{\alpha-1}$. (A ramified set is a partially ordered set in which the predecessors of each element form a chain.) *L. Gillman* (Rochester, N.Y.)

Vopěnka, Petr 5742

The independence of the continuum hypothesis. (Russian. English summary)

Comment. Math. Univ. Carolinae **5** (1964), *suppl. I*, 48 *pp.*

The following theorems are proved in this paper. (1) If the Gödel-Bernays set theory Σ^* is consistent, then it remains consistent after adjunction of any of the formulas (i) $2^{\aleph_0} \geq \aleph_n$; (ii) $2^{\aleph_0} \geq \aleph_\omega$; (iii) $2^{\aleph_0} \geq \aleph_{\omega_1}$, etc. (2) Let In be the axiom: "There is at least one regular aleph $\aleph$ with a positive limit index". If $\Sigma^* + \mathrm{In}$ is consistent, then it remains consistent after adjunction of the axiom: "There is a regular aleph with a positive limit index such that $\aleph \leq 2^{\aleph_0}$".

These theorems were proved earlier by Cohen [Proc. Nat. Acad. Sci. U.S.A. **50** (1963), 1143–1148; MR **28** #1118; ibid. **51** (1964), 105–110; MR **28** #2962] for Zermelo-Fraenkel set theory. The author's proof, while using essential ideas of Cohen's proof, differs considerably from the latter.

The first difference is that the author does not construct a semantical model for $\Sigma^* + $ (i) (or $\Sigma^* + \mathrm{In} + $ (ii)) but interprets these systems in Σ^*. In other words, he defines a class E of ordered pairs (by a normal formula) and proves that the axioms of $\Sigma^* + $ (i) [respectively, (ii)] are transformed in theorems of Σ^* if one substitutes E for $\in$. Since there are only finitely many axioms in Σ^* this proof can be carried out in Σ^* and does not require metamathematical arguments.

The basic tool is—as in Cohen's work—the notion of forcing. This notion is, however, for the author not a metamathematical one: He defines (again by a normal formula) a class Forc of triples $\langle p, \alpha, \beta \rangle$, where p is an open subset of a topological space c and α, β are ordinals. The formula $\langle p, \alpha, \beta \rangle \in$ Forc means that p forces the "limited statement $F_\alpha \in F_\beta$", where F_α and F_β are polynomials defined as in Cohen's paper.

The operation of adjunction of new sets to a given model is replaced in the author's proof by the ultraproduct operation. The field of his relation E consists of continuous functions φ defined on open dense subsets of c whose values are polynomials, discrete topology being used in the space of polynomials. A pair $\langle \varphi, \psi \rangle$ belongs to E if the union $\bigcup \{p : \langle p, \varphi(p), \psi(p) \rangle \in \text{Forc}\}$ belongs to a fixed ultrafilter $j \subset P(c)$ containing all open dense subsets of c. Functions φ which are not almost equal to a constant thus define "new sets".

The model ∇ obtained in this way satisfies the axioms of Σ; an additional construction is necessary to verify that the axiom of choice be true in the model.

In order to obtain the proofs of Theorems 1 and 2, the author has still to choose a suitable space c. He shows that formulas (i) and (ii) are satisfied in ∇ if c is the topological product of ν copies of the Cantor discontinuous space, where ν is $\aleph_n$, $\aleph_\omega$, $\aleph_{\omega_1}$ in case (i), and ν is the first regular aleph with a positive limit index in case (ii).

Finally, the author shows that there is an ordinal ν^* of the model ∇ (which can be made arbitrarily large by a suitable choice of ν) such that cardinals of ∇ which are $< \nu^*$ are absolute (i.e., coincide with cardinals of the model Δ constructed in ∇).

It is obvious that the author's method is not necessarily limited to the choice of c specified above but can be adapted to a multitude of other situations.

All proofs in the paper are given in full and with a

laudable precision; as it often happens, the precision is pushed so far that it sometimes makes the reading very hard. *A. Mostowski* (Warsaw)

Vopěnka, Petr; Bukovský, Leo 5743

The existence of a PCA-set of cardinal $\aleph_1$.

Comment. Math. Univ. Carolinae **5** (1964), 125–128.

The authors show that for a suitable ordinal ν the model V constructed by Vopěnka [cf. #5742 above] has the property that the formula $\mathrm{card}(L \cap N^N) = \aleph_1 < 2^{\aleph_0}$ is satisfied in V. Using a theorem of Addison [Fund. Math. **46** (1959), 337–357; MR **22** #A1523], who showed that $L \cap N^N \in \mathrm{PCA}$, the authors conclude that if the Gödel-Bernays set theory Σ is consistent, then the theorem "every non-denumerable PCA-set of irrationals is of power $2^{\aleph_0}$" is undecidable in Σ. *A. Mostowski* (Warsaw)

Erdős, P. 5744

An interpolation problem associated with the continuum hypothesis.

Michigan Math. J. **11** (1964), 9–10.

The note deals with families of analytic functions $f: K \to K$, K being the set of complex numbers. Such a family F is said to have the property P_0 provided that for every $z \in K$ the set $\{f(z); f \in F\}$ is countable. Answering a question of Wetzel, the author proves the following. If $c > \aleph_1$, every family F of analytic functions with the property P_0 is countable. If $c = \aleph_1$, some family of analytic functions with the property P_0 has cardinal c. The author asks whether for some family of distinct analytic functions f_α $(\alpha < \Omega_c)$ the set $\{f_\alpha(z)\}_\alpha$ has cardinal $< c$ for every complex number z. *Đ. Kurepa* (Zagreb)

Keisler, H. Jerome 5745

Ultraproducts and saturated models.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 178–186.

The author introduces the notion of an α-saturated structure, which is a refinement of the notion of a homogeneous universal model. A structure $\mathfrak{A}$ is said to be α-saturated, where α is a cardinal number, if for each sequence $\{a_\lambda\}_{\lambda<\xi}$, where $\xi < \alpha$, and every set Γ of formulas of the first-order language of $\mathfrak{A}$ with constants for the members of $\{a_\lambda\}_{\lambda<\xi}$ and with x as the only free variable if for every finite $\Lambda \subseteq \Gamma$ $(\exists x) \bigwedge_{\varphi \in \Lambda} \varphi(x)$ is true in $\mathfrak{A}$, then also $(\exists x)(\bigwedge_{\varphi \in \Gamma} \varphi(x))$ is true in $\mathfrak{A}$. The central theorem asserts that for appropriate sets I and ultrafilters D on I and for all structures $\mathfrak{A}_i$, $i \in I$ (of appropriate type), the ultraproduct $\prod_{i \in I} \mathfrak{A}_i/D$ is α-saturated. A consequence of this is that, assuming the generalized continuum hypothesis, two structures are elementary equivalent if and only if they have isomorphic ultrapowers. The paper contains a further discussion of the connections between the author's notion of good ideals [Ann. of Math. (2) **79** (1964), 338–359; MR **29** #3383] and α-saturated structures. The paper concludes with several (counter-)examples.

A. Lévy (Jerusalem)

Gaifman, Haim; Specker, E. P. 5746

Isomorphism types of trees.

Proc. Amer. Math. Soc. **15** (1964), 1–7.

A normal $\aleph_\alpha$ tree is any tree $(A, \leq)$ satisfying the following five conditions (N_1)–(N_5). (N_1) Every row is of power $\aleph_\alpha$; (N_2) Every node of the second [first] kind has $\aleph_\alpha$ points [a single point]; (N_3) Every point x of A has successors in every row of rank $> \rho(x)$ [$\rho(x)$ is the rank of x]; (N_4) Every path (i.e., every subchain that is an initial section) has $< \aleph_{\alpha+1}$ points; (N_5) To every path of cardinality $< \aleph_\alpha$ corresponds some point $x \in A$ which is a successor of every point of the path (for $\alpha = 0$ see the "suites distinguées" of the reviewer [Publ. Math. Univ. Belgrade **4** (1935), 1–138; Ph.D. Dissertation, Univ. Paris, Paris, 1935, in particular, p. 99]).

The authors prove the following. For every ordinal α such that $\aleph_\alpha^{\aleph_\xi} = \aleph_\alpha$ for every ordinal $\xi < \alpha$ there are at least $\aleph_{\alpha+2}$ isomorphism types of normal $\aleph_\alpha$ trees (the authors announce that the stronger wording also holds and is obtained from the foregoing by the substitution: "at least $\aleph_{\alpha+2}$" by "exactly $2^{\aleph_{\alpha+1}}$"). The proof is based on the existence of normal $\aleph_\alpha$ trees (cf. Aronszajn: $\alpha = 0$ in the reviewer's thesis [loc. cit.] and particularly in the reviewer's papers [Publ. Math. Univ. Belgrade **6/7** (1937), 129–160; Acta Math. **75** (1943), 139–150; MR **7**, 195]; see also Specker [Colloq. Math. **2** (1949), 9–12; MR **12**, 597]) and by the formation of new trees by the composition of those given. *Đ. Kurepa* (Zagreb)

Halberstam, H.; Laxton, R. R. 5748

Perfect difference sets.

Proc. Glasgow Math. Assoc. **6**, 177–184 (1964).

Let Π be the projective plane over $\mathrm{GF}(p^n)$, and C a collineation of Π of period $q = p^{2n} + p^n + 1$. If the points of Π are denoted by $0, 1, \cdots, q-1$, where $C(i) = i+1$, then the points of any line of Π form a perfect difference set mod q, called a Singer difference set (S.d.s.). The authors give a new proof of the theorem that the only multipliers of such a set are the powers of p (mod q). They then show that if A and B are any two S.d.s.'s (mod q), there is an integer t with $(t, q) = 1$ such that tA and B are equivalent (i.e., translates of each other mod q). Combining these results, it follows that the number of inequivalent S.d.s.'s (mod q) is $\varphi(q)/3n$. {Actually the paper deals only with the case where C is the collineation induced in $\Pi = \mathrm{GF}(p^{3n})^*/\mathrm{GF}(p^n)^*$ by the map $\alpha \to \zeta\alpha$ of $\mathrm{GF}(p^{3n})^*$

onto itself, where ζ is a generator of $GF(p^{2n})^*$. However, it is easily seen using canonical forms that every S.d.s. is equivalent to one obtained in this way.}

On the lottery problem. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **9** (1964), 155–158.

Let S be a system of combinations of k elements out of a set E of n elements such that every combination of l elements has at least d elements in common with a combination of S. Let N be the number of combinations of S and $N_0 = \min_S(N)$. The authors prove

(1) $$N_0 \geq \frac{n(n-l+1)}{k(l-1)^2};$$

(2) $$N_0 \sim \frac{n(n-l+1)}{k(l-1)^2};$$

(3) If $k \leq 5$ and $n/(l-1)$ is integral and $\equiv 1$ $(k-1)$, then equality holds in (1).

H. B. Mann (Madison, Wis.)

Lindström, Bernt 5750

On a combinatory detection problem. I. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **9** (1964), 195–207.

The present paper is an outgrowth of a paper by H. S. Shapiro and S. Söderberg on a coin-weighing problem [Amer. Math. Monthly **70** (1963), 1066–1070]. A family of subsets $T_1, T_2, \cdots, T_m$ of a given set S of $|S| = n$ elements is a detecting family for S if each subset M of S is uniquely determined by the m numbers $|M \cap T_i|$ $(i = 1, \cdots, m)$. The basic problem is to evaluate $f(n) = \min m$ over the class of all detecting families for S. It is easy to verify that $f(4) = 3$ and $f(5) = 4$, but the evaluation of $f(n)$ for general n appears hopelessly difficult. P. Erdős and A. Rényi, as well as B. Gordon, L. Moser, and the author, have shown that

(1) $$\liminf_{n\to\infty} \frac{f(n)\log n}{n} \geq \log 4.$$

The main result of this paper is that

(2) $$\limsup_{n\to\infty} \frac{f(n)\log n}{n} \leq \log 4,$$

whence

(3) $$\lim_{n\to\infty} \frac{f(n)\log n}{n} = \log 4.$$

This confirms a conjecture of Erdős and Rényi on the existence of the limit. A critical theorem in the derivation of (2) is the inequality

(4) $$f(k2^{k-1}) \leq 2^k - 1 \qquad (k = 2, 3, \cdots),$$

and this is derived by the construction of a certain "detecting matrix". The paper also contains another derivation of (1) based on information theory. The paper concludes by developing an analogous theory for a related detection problem of Erdős and Rényi.

H. J. Ryser (Syracuse, N.Y.)

Lindsey, John H., II 5751

Assignment of numbers to vertices.

Amer. Math. Monthly **71** (1964), 508–516.

The author proves the following theorem. The class of assignments of numbers to vertices of a rectangular parallelepiped of lattice points $(a_1, a_2, \cdots, a_n)$ in n-dimensions of sides l_1, $l_1 \geq l_2 \geq \cdots \geq l_n$, where $0 \leq a_i \leq l_i$, $1 \leq i \leq n$, which minimize the sum of the absolute values of the differences of the numbers assigned to neighboring vertices (two vertices agreeing in all but one coordinate being called neighbors) is exhausted by assignments of the following type: For any fixed i such that $l_i = l_n$, we number the points $(a_1, \cdots, a_n)$ such that $a_i = \pi(1)$; the order in which these points are numbered is governed by induction on n. Then we number the points $(a_1, \cdots, a_n)$ such that $a_i = \pi(2)$, etc., where π is a permutation of $0, 1, \cdots, l_i$.

N. S. Mendelsohn (Winnipeg, Man.)

Carlitz, L.; Riordan, J. 5752

Two element lattice permutation numbers and their q-generalization.

Duke Math. J. **31** (1964), 371–388.

A two-element lattice permutation can be described in a two-dimensional lattice as a path leading from $(0, 0)$ to a point (n, m) (where $0 \leq m \leq n$) with the conditions that the path has minimum length, viz., $m + n$, and that it does not contain points (a, b) with $a < b$. It can also be described as an election for two candidates A, B with final vote (n, m), which is such that none of the partial results gives a majority for B (in the paper it is less accurately said that all partial results correctly predict the winner). The number $a_{n,m}$ of such two-element lattice permutations was determined in 1887 by J. Bertrand [see P. A. MacMahon, *Combinatory analysis*, Vol. I, Section III, Chapter V. Cambridge Univ. Press, Cambridge, 1915] as

$$a_{n,m} = (n+1-m)(n+1)^{-1}\binom{n+m}{m}.$$

The authors consider $a_n(x) = \sum_{m=0}^{n} a_{n,m} x^m$ and show that this nth degree polynomial is characterized by the property that $(1-x)^{n+1}a_n(x)$ has the form $1 - xP_n(x(1-x))$, where P_n is again an nth degree polynomial; in fact, $P_n(u) = \sum_{m=0}^{n} a_{m,m} u^m$. A number of relations are derived for the generating function $a(x, y) = \sum_{n=0}^{\infty} x^n a_n(y)$.

The authors consider these formulas as the special cases $(q = 1)$ of a q-generalization. They define the nth degree polynomial $a_n(x, q)$ by the condition that there exist $c_0, \cdots, c_n$ such that

$$(x)_{n+1} a_n(x, q) = 1 - x \sum_{m=0}^{n} c_m (qx)^m (x)_m,$$

where $(x)_k$ denotes $(1-x)(1-qx)\cdots(1-q^{k-1}x)$. The coefficients $a_{n,m}(q)$ of this polynomial are studied in several ways.

{The reviewer remarks that $a_{n,m}(q)$ has the following combinatorial interpretation: It is the sum of all $q^{k_1+\cdots+k_m}$, where $k_1, \cdots, k_m$ are integers subject to the conditions $1 \leq k_1 \leq \cdots \leq k_m \leq n$, $k_1 \geq 1, \cdots, k_m \geq m$.}

N. G. de Bruijn (Eindhoven)

Carlitz, L. 5753

The generating function for $\max(n_1, \cdots, n_k)$.

Portugal. Math. **21** (1962), 201–207.

For $k \geq 1$ and $1 \leq r \leq k$, define M_r^k (briefly, M_r) to be the k-place function that selects the rth smallest member from a given set of k real numbers. Thus $M_1 = \min$, $M_k = \max$, while for $k = 3$, M_2 coincides with the function sometimes called "mid". The author evaluates the (formal) multiple power series

$$\mathfrak{M}_r^k = \sum_{n_1,\cdots,n_k=0}^{\infty} M_r(n_1, \cdots, n_k) x_1^{n_1} \cdots x_k^{n_k}$$

in closed form. To illustrate, we give the closed expressions for $(1-x_1)(1-x_2)(1-x_3)\mathfrak{M}_r^3$, $r = 1, 2, 3$. These are, respectively,

$$\frac{x_1x_2x_3}{1-x_1x_2x_3} \qquad (r = 1);$$

$$\frac{x_1x_2}{1-x_1x_2} + \frac{x_2x_3}{1-x_2x_3} + \frac{x_3x_1}{1-x_3x_1} - 2\frac{x_1x_2x_3}{1-x_1x_2x_3} \qquad (r = 2);$$

$$\frac{x_1}{1-x_1} + \frac{x_2}{1-x_2} + \frac{x_3}{1-x_3} - \frac{x_1x_2}{1-x_1x_2} - \frac{x_2x_3}{1-x_2x_3} - \frac{x_3x_1}{1-x_3x_1} + \frac{x_1x_2x_3}{1-x_1x_2x_3} \qquad (r = 3).$$

On a restricted random walk.

Norske Vid. Selsk. Forh. (*Trondheim*) **37** (1964), 91–94.

The random walk is of unit steps, right or left, on a line, with no steps to the left of the start point. It is shown that g_{nk}, the number of such walks with n steps and final point k, is given by

$$g_{n,n-2k} = \binom{n}{k} - \binom{n}{k-1}, \qquad k = 0, 1, \cdots, m,$$

with m the integral part of $\frac{1}{2}n$ ($g_{n,n-2k-1} = 0$). As an immediate consequence, the total number with n steps, the sum of the g_{nk}, is $\binom{n}{m}$, a result also obtained (without specific identification in present terms) by Ora Engelberg [J. Appl. Probability **1** (1964), 168–172; MR **28** #4561]. It is interesting to notice that $g_{n,n-2k} = a_{n-k,k}$, where a_{nm} is the number of lattice permutations with n elements of one kind, m of a second, and $n \geq m$ (the numbers associated with the simplest ballot problem), a mapping which gives the main result at once. *J. Riordan* (Murray Hill, N.J.)

Erdős, P.; Moser, L. 5756

On the representation of directed graphs as unions of orderings. (**Russian summary**)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **9** (1964), 125–132.

If m voters each rank n candidates in order of preference, an oriented graph may be formed in which an arc is oriented from vertex i to vertex j if and only if candidate i is ranked above candidate j by more than half the voters. Let $m(n)$ denote the smallest number of voters for which it is possible to obtain every oriented graph with n vertices in this way. Stearns [Amer. Math. Monthly **66** (1959), 761–763; MR **21** #7799] showed that $m(n) > c_1 n/\log n$, and here it is shown that $m(n) < c_2 n/\log n$, where the c_i denote constants.

It is also shown that if $f(n)$ denotes the largest integer t such that every tournament with n vertices contains a transitive subtournament with t vertices, then $[\log_2 n] + 1 \leq f(n) \leq 2[\log_2 n] + 1$.

Fillmore, Peter A. 5757

An Archimedean property of cardinal algebras.

Michigan Math. J. **11** (1964), 365–367.

The concept of cardinal algebra has been introduced and investigated by A. Tarski [*Cardinal algebras*, Oxford Univ. Press, New York, 1949; MR **10**, 686]. A cardinal algebra A can be partially ordered by defining $a \leq b$ to mean $a + x = b$ for some $x \in A$. The author proves that if $na \leq (n+1)b$ holds for all $n < \infty$ ($a, b \in A$), then $a \leq b$.

Perles, Micha A. 5758

A proof of Dilworth's decomposition theorem for partially ordered sets.

Israel J. Math. **1** (1963), 105–107.

A theorem of Dilworth's states that if P is a partially ordered set in which the maximal number of elements in an independent subset is k, then P is the union of k chains. The author gives a simple inductive proof of this theorem when $|P|$ is finite and indicates how the general case can be deduced from the finite case.

J. McLaughlin (Ann Arbor, Mich.)

Perles, Micha A. 5759

On Dilworth's theorem in the infinite case.

Israel J. Math. **1** (1963), 108–109.

In answer to a question attributed to P. Erdős, the author exhibits, for each infinite cardinal $\aleph_\alpha$, a partially ordered set T_α such that (1) $|T| = \aleph_\alpha$, (2) T_α contains no infinite independent subset, (3) T_α is not decomposable into less than $\aleph_\alpha$ chains. This shows the impossibility of extending Dilworth's theorem [#5758 above] to the case where the cardinals of the independent subsets are not bounded.

Holland, Samuel S., Jr. 5760

Distributivity and perspectivity in orthomodular lattices.

Trans. Amer. Math. Soc. **112** (1964), 330–343.

A lattice L with 0 and 1 is "orthocomplemented" if L admits an order-reversing involution $a \to a^{\perp}$ such that $a^{\perp}$ is a complement of a for every a, and is "orthomodular" if $b = a \vee (b \wedge a^{\perp})$ for every $b \geqq a$. The lattice of projections in a von Neumann algebra is not modular, in general, but is always orthomodular, and the general question raised here is, roughly, whether it is possible to erect a structure theory of complete orthocomplemented lattices that will generalize projection lattices in the manner in which the theory of continuous geometries englobes the structure theory of the lattice of projections of a finite von Neumann algebra. By way of answer the author examines nine theorems that are valid in the lattice projections of an arbitrary von Neumann algebra (as well as in an arbitrary continuous geometry) and shows that two of them (when suitably reformulated) remain valid in a complete orthocomplemented lattice, but that the other seven do not. The more interesting of the two results that do generalize concerns the basic problem of adding perspectivities and goes as follows. Write $a \perp b$ if $b \leq a^{\perp}$ and $a \sim b$ if there exists an x such that $a \wedge x = b \wedge x = 0$ and $a \vee x = b \vee x = a \vee b$ ("strong perspectivity"). Let $\{a_\alpha\}$ and $\{b_\alpha\}$ be similarly indexed families in a complete orthocomplemented lattice L and suppose (1) $a_\alpha \vee b_\alpha \perp a_\beta \vee b_\beta$ for $\alpha \neq \beta$, and (2) $a_\alpha \sim b_\alpha$ for all α. Then $\bigvee_\alpha a_\alpha \sim \bigvee_\alpha b_\alpha$. *A. Brown* (Ann Arbor, Mich.)

Grätzer, G. 5761

Boolean functions on distributive lattices.

Acta Math. Acad. Sci. Hungar. **15** (1964), 195–201.

The author extends the notion of a Boolean function on a Boolean algebra, which was investigated in an earlier paper of the author [Rev. Math. Pures Appl. 7 (1962), 693–697], to a Boolean function on a distributive lattice L (with 0 and 1). A Boolean function on L is defined by the property that it enjoys the substitution property under any congruence relation on L. With every Boolean function $f(x_1, x_2, \cdots, x_n)$ there is associated a characteristic function φ of 2^n into L, and it is shown that φ determines f uniquely. Necessary and sufficient conditions are stated in order that a function $\varphi: 2^n \to L$ be a characteristic function. From this result several other results are derived. A Boolean function f is a lattice polynomial if and only if its characteristic function φ is monotone, and if and only if L contains no proper Boolean interval. It is also shown that a Boolean function f on a distributive lattice L with 0 and 1 can be uniquely extended to any Boolean algebra B that contains L as a sublattice. The author also investigates those Boolean functions which are automorphisms or dual-automorphisms. If $f(x)$ is a Boolean function on L, then the correspondence $x \to f(x)$ is an automorphism if and only if $f(x) = x$. *Ph. Dwinger* (Delft)

Karolinskaja, L. N. 5762

Congruence lattices on distributive lattices. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 1037–1054.

A class K of universal algebras is said to be abstract if $A \in K$ and $A \cong B$ imply $B \in K$. The author gives a characterization of congruence lattices $\Theta(L)$ for a given abstract class of distributive lattices L. These $\Theta(L)$ are characterized by the property of containing a sublattice C satisfying certain conditions. These conditions are satisfied by the sublattice C of all congruence relations $\Theta(I_a)$, defined as the smallest congruence relation under which the principal ideal I_a generated by $a \in L$ is a congruence class. Then L can be recognized as isomorphic to C. {Reviewer's remark: The condition (III) in Theorem 1 may be omitted.} *E. T. Schmidt* (Budapest)

van Albada, P. J. 5763

A self-dual system of axioms for Boolean algebra.

Nederl. Akad. Wetensch. Proc. Ser. A **67** = *Indag. Math.* **26** (1964), 377–381.

The author shows that a class B which (i) contains elements 0, 1 and a dual a' to any element a, (ii) is closed under addition and multiplication, and (iii) satisfies the (demonstrably independent) axioms

$$a(b+c) = ab+ac, \qquad (b+c)a = ba+ca,$$

$$a+bc = (a+b)(a+c), \qquad a+0 = 0+a = a,$$

$$aa' = 0, \qquad a1 = a, \qquad a+a' = 1$$

for all elements a, b, c, is a Boolean algebra. Thus, a Newman algebra is a Boolean algebra if and only if $a+bc = (a+b)(a+c)$ for all elements.

On representation of polyadic algebras.

Norske Vid. Selsk. Forh. (*Trondheim*) **37** (1964), 36–41.

A relatively short new proof of the well-known representation theorem for locally finite polyadic algebras is given. The paper is almost self-contained and includes a discussion of the equivalence of the representation theorem and the Gödel completeness theorem.

H. J. Keisler (Madison, Wis.)

Gaifman, H. 5765

Infinite Boolean polynomials. I.

Fund. Math. **54** (1964), 229–250.

The summary of results given in the Introduction to this important paper can hardly be improved by the reviewer. "This work treats Boolean polynomials (on a fixed set of variables) in which the operations of join, $\bigvee$, and meet, $\bigwedge$, may apply to sets of arbitrary high powers. Thus if X is any set of such polynomials, then $\bigvee X$ and $\bigwedge X$ are Boolean polynomials as well. If the variables of such a polynomial are given values in a complete Boolean algebra, then the polynomial has a value in this Boolean algebra, which is defined in a natural way, and two polynomials which always yield the same values for the same variables are identified. The main result of Part I is that the Boolean polynomials in $\aleph_0$ variables do not constitute a set."

Boolean polynomials are defined using Bernays set theory without the axiom of choice. The properties of the Boolean polynomials mentioned above are established, and the principal result that the Boolean polynomials in $\aleph_0$ variables do not form a set is proved. From this it follows directly that there is no completely free Boolean algebra with $\aleph_0$ generators. This corollary provides a negative answer to a question posed by L. S. Rieger [Fund. Math. 38 (1951), 35–52; MR 14, 347; errata,

MR 14, p. 1278]. The same result is proved more generally for the class of complete, (δ, ∞)-distributive Boolean algebras, generated by δ elements, where δ is any infinite regular cardinal. These results have been obtained independently using different methods by A. W. Hales [ibid. 54 (1964), 45–66; MR 29 #1162]. The results on Boolean polynomials are also used to prove theorems on the power of the free α-complete Boolean with β generators; for example, if B is such an algebra then the cardinality of B is at least $\max\{\alpha, \beta\}$. *R. S. Pierce* (Seattle, Wash.)

Some properties of Bernoulli schemata. (Russian. English summary)

Mat.-Fyz. Časopis Sloven. Akad. Vied **14** (1964), 83–88.

Die Verfasser definieren eine Invariante in einer Booleschen σ-Algebra mit einem gegebenen Automorphismus. Es sei $A(n)$ die Algebra von allen Teilmengen einer Menge mit n Elementen, in der ein Mass definiert ist, welches den Wert $1/n$ für alle Mengen, die nur einen Punkt besitzen, erreicht. In einem gewissen cartesischen Produkt $P(n)$ von abzählbar vielen Exemplaren der Algebra $A(n)$ wird ein Automorphismus auf eine natürliche Weise definiert. Mit Hilfe der eingeführten Invariante wird gezeigt, dass für $n \neq m$ die Algebren $P(n)$, $P(m)$ nicht isomorph sind. Ähnliche Resultate sind auch für gewisse Quotientenalgebren von $P(n)$ in Kraft, welche die Verfasser Bernoullische dynamische Systeme nennen.

Andreoli, Giulio 5767

Catene booleane e markowiane di partizioni; tassinomie ed algoritmi sugli alberi.

Ricerca (Napoli) (2) **13** (1962), *settembre–dicembre*, 3–12.

A given set is partitioned into pairwise disjoint subsets, and this initial partitioning is iterated for the subsets, altogether an indexed number of times. The final class of subsets, together with the intermediate stages, can be regarded as a hierarchy of Boolean orthonormal algebras under the usual operations. But the process also provides what is known as a "tree" in the literature of finite mathematics. In the set-theoretic interpretation certain measure-theoretic concepts are applicable. If each subset within a partition is assigned a measure (say area), then the chain of partitions created can be typical of a Markov chain. A given sequence (chain) of successive partitions

$$\Pi^{(0)}, \Pi_r', \Pi_{rs}'', \Pi_{rst}''', \cdots, \Pi^{(\nu)}$$

is called by the author a "taxonomy" (tassinomia). For the tree analogy, an intermediate or final subset determines an oriented path through the taxonomy.

There is defined a "product" of two partitions of a set (the totality of intersection sets) and through this a product of two taxonomies over the same initial set. Two partitions are called independent if the measure of the Boolean (set) product is the numerical product of the subset measures; the paper deals only with independent partitions. Some algorithmic properties are developed, as well as a sum operation and an exploration of lattice properties under the suitable bound definitions. Taxonomies over two initial sets are handled via Cartesian product. The paper is exploratory and vaguely suggestive of eventual application to stochastic processes.

Andreoli, Giulio 5768

Algoritmi booleani subordinati ad algoritmi numerici conversi. Algebre di Frobenius-Boole.

Ricerca (Napoli) (2) **14** (1963), *gennaio–aprile*, 3–9.

A hypercomplex system in which the usual operator ring or field is replaced by a Boolean algebra, with the structure constants belonging to the minimal (zero-one) algebra, is identified as a "Frobenius algebra" if, when $A_rA_s = A_t$ for the underlying group, the constants $\gamma_{rs\rho}$ are unity for $\rho = t$ and zero otherwise. A generalization introduced is to allow $u_ru_s = \sum \gamma_{rs\rho} u_\rho$, where the ρ take on exclusively zero and unit values.

A primitive Frobenius-Boolean algebra is essentially an n-atomic Boolean algebra whose atoms are the basis elements, and any Frobenius algebra is a direct sum of such primitive algebras. An algebra is "convex" if in any basis the structure constants are non-negative. Those Frobenius algebras whose basis elements are precisely the elements of the underlying group are convex algebras. The Boolean algebra of n atoms is a particular case of a transition algebra; and in the opposite sense a transition algebra is a convex algebra in which the coefficient set is related to a Boolean algebra.

Théorie générale de la disjonction.

C. R. Acad. Sci. Paris **258** (1964), 34–37.

The author studies disjoint subsets of a φ-space [N. Bourbaki, *Les structures fondamentales de l'analyse*, Livre I, Théorie des ensembles, Chapitre III, § 4, no. 5; ibid. Chapitre III, § 3, no. 3; Actualités Sci. Indust., No. 1243, Hermann, Paris, 1956; MR 17, 1062]. He generalizes the notion of linear or algebraic disjointness of two sets. The paper is a statement of results, detailed proofs to be published at a later date. *S. Rubinstein* (Seattle, Wash.)

Dlab, V. 5770

A generalization of dependence relations.

Proc. Colloq. Abelian Groups (Tihany, 1963), pp. 49–50. *Akadémiai Kiadó, Budapest*, 1964.

Apart from an exposition of an earlier paper [Publ. Math. Debrecen **9** (1962), 324–355; MR 27 #81], the author gives without proof the following result. Let δ be a generalized algebraic dependence relation for S. Then there exist a set L and a one-to-one mapping ϕ of $\mathfrak{P}(S)$ onto $\mathfrak{P}(L)$ such that

$$X_1 \subseteq X_2 \quad \text{if and only if} \quad \phi(X_1) \subseteq \phi(X_2)$$

and

$$[x, X] \in \delta \quad \text{if and only if} \quad (\phi(x)) \cap \phi(X) \neq \varnothing.$$

O. Pretzel (Berlin)

Foster, Alfred L.; Pixley, Alden F. 5771
Semi-categorical algebras. II.
Math. Z. **85** (1964), 169–184.

Part I appeared earlier [same Z. **83** (1964), 147–169; MR **29** #1165]. As in Part I, the authors consider algebras of arbitrary but fixed species $S=(n_1, n_2, \cdots)$. At first, semi-primal algebras are characterized in terms of properties of the lattice of congruence relations. Notation: With each set $\mathfrak{U}$ of S-identities is associated the equational class $C(\mathfrak{U})$ of all algebras of species S satisfying the members of $\mathfrak{U}$. The members of $C(\mathfrak{U})$ are called $\mathfrak{U}$-algebras or, if $\mathfrak{U}$ consists of the identities $|\mathfrak{A}|$ satisfied by an algebra $\mathfrak{A}$, $\mathfrak{A}$-algebras. When all of the algebras of $C(\mathfrak{U})$ have permutable congruence relations [a distributive lattice of congruence relations], then $\mathfrak{U}$ is said to be a permutable [distributive] set of identities. Theorem 3.1: An algebra $\mathfrak{A}$ is semi-primal if and only if (a) $\mathfrak{A}$ is finite, having at least two elements; (b) The subalgebras of $\mathfrak{A}$ are simple and have no proper automorphisms and no two distinct subalgebras of more than one element are isomorphic; (c) The identities $|\mathfrak{A}|$ are both permutable and distributive.

While every subalgebra of a semi-primal algebra is simple, this is not generally true of semi-categorical algebras. This leads to the definition: $\mathfrak{A}$ is quasi-simple if all homomorphic images of subalgebras of $\mathfrak{A}$ are isomorphic with subdirect products of subalgebras of $\mathfrak{A}$. Theorem 5.4 (general representation theorem): If $\mathfrak{A}$ is a finite algebra having at least two elements and satisfying (a) $\mathfrak{A}$ is quasi-simple, and (b) $|\mathfrak{A}|$ are distributive identities, then $\mathfrak{A}$ is semi-categorical. Theorem 6.1 (on direct product representations): If $\mathfrak{A}$ is a semi-categorical algebra having permutable identities and having no simple subalgebras, then every finitely generated $\mathfrak{A}$-algebra is isomorphic with the direct product of subalgebras of $\mathfrak{A}$. There is also a partial converse of this theorem. Applications to semi-categorical lattices and to commutative rings.

H.-J. Hoehnke (Berlin)

Grätzer, G. 5772
On the class of subdirect powers of a finite algebra.
Acta Sci. Math. (*Szeged*) **25** (1964), 160–168.

Let $\mathfrak{A}$ be a finite algebra with a finite number of finitary operations, and let $\mathrm{Sp}(\mathfrak{A})$ denote the class of sub-direct products of copies of $\mathfrak{A}$. The author gives a sufficient condition for $\mathrm{Sp}(\mathfrak{A})$ to be an elementary class (defined by a single closed sentence). The condition is too complicated to give here in detail, but it may be stated roughly as follows: For some positive integer N, every finite system of equations with no solution in $\mathfrak{A}$ entails a similar system with at most N unknowns. The chain of length n, considered as a lattice, satisfies this condition with $N=n$, whence the class of n-bounded lattices is elementary, a result of Anderson and Blair [Math. Ann. **143** (1961), 187–211; MR **25** #2988]. The theorem also covers several other well-known examples and carries over to relational systems with minor changes. The author gives an example to show that $\mathrm{Sp}(\mathfrak{A})$ is not always elementary and concludes by listing a number of related problems.

P. J. Higgins (London)

Janov, Ju. I. 5773
Systems of identities for algebras. (Russian)
Problemy Kibernet. No. 8 (1962), 75–90.

Let $F(X)$ be the free algebra of some finitary species $(n_1, \cdots, n_m)$, $m<\aleph_0$, X being the set of free generators, card $X=\aleph_0$. For any binary relation Σ on $F(X)$ let its closure $R\Sigma$ be the least congruence such that $f\Sigma g$ ($f, g \in F(X)$) implies $\eta(f)R\Sigma\eta(g)$ for any endomorphism $\eta: F(X)\to F(X)$. For any algebra A of the given species define $\Sigma(A)$ on $F(X)$ by putting $f\Sigma(A)g$ if and only if $\vartheta(f)=\vartheta(g)$ for any homomorphism $\vartheta: F(X)\to A$. The existence of a finite A with $R\Delta\neq\Sigma(A)$ for all finite $\Delta\subset\Sigma(A)$ has been proved by R. C. Lyndon [Proc. Amer. Math. Soc. **5** (1954), 8–9; MR **15**, 676]. The closure operation R satisfying $\Sigma\subset R\Sigma=RR\Sigma$ and $R\Sigma(A)=\Sigma(A)$ is replaced by the author by S_n ($n=1, 2, \cdots$) defined in the following manner. Consider all mappings $\sigma: X\to X$ with card $\sigma(X)\leq n$ and their extensions to homomorphisms $\bar\sigma: F(X)\to F(X)$. Define $fS_n\Sigma g$ if and only if $\bar\sigma(f)R\Sigma\bar\sigma(g)$ for all $\bar\sigma$'s described above. Hence $R\Sigma\subset S_n\Sigma$, and since $S_nS_n\Sigma=S_n\Sigma$, we have $RS_n\Sigma=S_nR\Sigma=S_n\Sigma$ for any natural n. The author proves that for any finite A with card $A=n$ there exists a finite $\Delta\subset\Sigma(A)$ with $S_n\Delta=\Sigma(A)$.

The paper also concerns some other questions. Equationally complete Σ's are considered (i.e., those for which $R\Sigma$ is maximal) and for this property a necessary and sufficient condition is found. Next, some conditions are given for A under which $\Sigma(A)\subset\Sigma(A')\neq F(X)\times F(X)$ for some algebra A' with $\Sigma(A')=R\Delta$ for some finite Δ.

The author uses the language of formulae, identities, etc., rather than the language of free algebras and homomorphisms used here by the reviewer for brevity. For R and S_n intrinsic definitions are given.

Bojarincev, A. E. 5774
Some generalizations of Wilson's theorem. (Russian)
Ural. Gos. Univ. Mat. Zap. **3**, *tetrad* 3, 21–24 (1962).

It is well known that Wilson's congruence, $(p-1)!\equiv -1 \pmod p$, holds if and only if $p>1$ is prime. The author proves these generalizations. If $m>0$ is an integer, and $p\geq m$, then p is prime if and only if $(m-1)!(p-m)!\equiv(-1)^m \pmod p$. If also n is a positive integer, then p is prime if and only if

$$\frac{(m-1)!(np-m)!}{(n-1)!p^{n-1}}\equiv-(-1)^{m+n} \pmod p.$$

If $n>0$ is even, and $p\nmid n$, then p and $p+n$ are both prime if and only if $[(n!-1)p-n](p-1)!\equiv n \pmod{p(p+n)}$.

W. J. LeVeque (Ann Arbor, Mich.)

Brown, J. L., Jr. 5775
Generalized bases for the integers.
Amer. Math. Monthly **71** (1964), 973–980.

The author proves the following theorem: Let f_i, k_i, m_i ($i=1, 2, 3, \cdots$) be integers, the f_i being positive and the k_i and m_i being non-negative. Any integer n such that $-\sum_1^N m_if_i\leq n\leq\sum_1^N k_if_i$ can be expressed uniquely in the form $n=\sum_1^N \alpha_if_i$, where each α_i is an integer satisfying

$-m_i \leq a_i \leq f_i$ if and only if $f_{s+1} = 1 + \sum_1^s (k_i + m_i) f_i$. A number of interesting special cases are studied.

Vorobyov, N. N. [Vorob'ev, N. N.] 5777

★The Fibonacci numbers.

Translated and adapted from the first Russian edition (1951) by Norman D. Whaland, Jr., and Olga A. Titelbaum. Survey of Recent East European Mathematical Literature, a project conducted by Alfred L. Putnam and Izaak Wirszup. Topics in Mathematics.

D. C. Heath and Co., Boston, Mass., 1963. v+47 pp. \$1.40.

This is one of a series of booklets "Topics in Mathematics" translated and adapted from the Russian series of Popular Lectures in Mathematics. As stated, "the purpose of these booklets is to introduce the reader to various aspects of mathematical thought and to engage him in mathematical activity of a kind that fosters habits leading to independent creative work. The series will make available to students of mathematics at various levels, as well as to other interested readers, valuable supplementary material to further their mathematical knowledge and development." "Each booklet is largely self-contained."

This particular booklet is elementary in nature, and can be interesting to people with two years of high-school algebra: students, as well as those who work mathematical problems for recreation. It deals with the elementary properties of Fibonacci numbers, their applications to geometry, and their connection with the theory of continued fractions.

Specifically, the contents are as follows: A historical introduction. Chapter 1, simplest properties of Fibonacci numbers—sums, sums of squares and other sums, connections with binomial coefficients, the Binet formula, sums of related series, computing Fibonacci numbers with large indices. Chapter 2, number-theoretical properties of the Fibonacci numbers—euclidean algorithm, commensurable and incommensurable line segments, properties of greatest common divisors, divisibility properties of Fibonacci numbers. Chapter 3, the Fibonacci numbers and continued fractions—definitions of continued fractions, convergents, particular continued fractions, Fibonacci numbers and the euclidean algorithm, continued fraction expansion of real numbers. Chapter 4, the Fibonacci numbers and geometry—mean proportional, the Golden Section, regular decagons, Golden Rectangles.

On the whole, the translators have rendered a valuable service in making the contents of this booklet accessible to English-speaking students.

Ehrhart, Eugène 5778

Sur un problème de partition d'un nombre.

C. R. Acad. Sci. Paris **259** (1964), 2746–2747.

Let $a_1 = 2, \cdots, a_{16} = 53$ be the first 16 primes, and write C_n for the number of solutions of the equation $\sum_{i=1}^{16} a_i X_i = 0$ in integers $X_i \geq 0$. There is a polynomial $P(n)$ of degree 15 such that C_n is the nearest integer to $P(n)$.

B. J. Birch (Manchester)

Ehrhart, Eugène 5779

Sur la partition des nombres.

C. R. Acad. Sci. Paris **259** (1964), 3151–3153.

Author's summary: "The functions C_n, C_n' which count, respectively, the non-negative and the positive solutions of the diophantine equation $\sum_{i=1}^{k} a_i X_i = n$ are related by $C_n' = (-1)^{k-1} C_{-n}$. Application: If the a's are coprime by pairs, then $C_n = P(n) + \psi(n)$, where $\psi(n)$ is periodic; $P(n)$ can now be given a relatively concise form."

{The reviewer presumes that the a's are positive integers and that, for $-n<0$, C_{-n} is defined to be $P(-n)+\psi(-n)$; owing to the lack of a definition for C_{-n}, the proof appears incomplete, though the results are essentially correct.}

On Catalan's problem.

Acta Arith. **9** (1964), 285–290.

Catalan's equation $x^p - y^q = 1$ is discussed for the case p, q prime, $p>3$, $q>3$, $p\equiv 3 \pmod 4$, and q does not divide the class number $h(p)$ of the quadratic field $k(\sqrt{-p})$. If these conditions hold and if there is a non-zero integral solution x, y, then it is shown that $p^q \equiv p \pmod{q^2}$, $x \equiv 0 \pmod{q^2}$, and $y \equiv -1 \pmod{q^{2p-1}}$. If we also have $p>q$ and $q\equiv 3 \pmod 4$, then the roles of p and q can be reversed to obtain additional conditions. These results imply that Catalan's equation is unsolvable for a large number of pairs p, q.

Una osservazione sull'ultimo teorema di Fermat. (English summary)

Rend. Accad. Sci. Fis. Mat. Napoli (4) **30** (1963), 281–286.

On sait que le dernier (ou grand théorème) de Fermat s'énonce comme suit : L'équation diophantienne

$$(1) \qquad x^n = y^n + z^n,$$

n entier >2, est impossible en entiers rationnels tous $\neq 0$. On sait que ce théorème n'a pas encore été démontré pour tout nombre premier n.

Dans cette note, l'auteur établit un critère pour l'existence éventuelle de solutions de l'équation (1) en entiers positifs tous $\neq 0$. Il y expose en effet une méthode ramenant la recherche de solutions éventuelles de (1) à celle des solutions représentant un certain nombre impair

positif moyennant une forme canonique (quadratique binaire), m étant un nombre positif impair, il s'agit d'une représentation de la forme

$$(2) \qquad m = \xi x^2 - \eta y^2.$$

L'auteur note cette forme $(\xi, -\eta)$, où ξ et η sont supposés premiers entre eux, et où x et y sont des entiers positifs premiers entre eux et respectivement premiers avec η et ξ. Il démontre le théorème suivant : Si un nombre positif impair est représentable par (2), alors il est représentable, d'une infinité de façons, par des nombres positifs qui peuvent être rangés, à partir de deux solutions minimales, en deux suites de nombres croissants. Moyennant ce théorème, il arrive à un critère pour l'existence éventuelle d'une solution (ξ^k, η^k, ζ^k), qui représente ζ^{2k+1} par la forme $(\xi, -\eta)$, $2k+1 \geq 3$, ξ et η étant supposés de parité différente, donc ζ impair (ξ^k, η^k, ζ^k) étant une solution primitive en entiers positifs de l'équation (1) que nous écrirons sous la forme

$$(1') \qquad x^n - y^n = z^n,$$

$$(1'') \qquad \xi^{2k+1} - \eta^{2k+1} = \zeta^{2k+1}.$$

(1″) peut évidemment s'écrire sous la forme $\xi(\xi^k)^2 - \eta(\eta^k)^2 = \zeta^{2k+1}$ d'où il résulte que (ξ^k, η^k) est une solution représentant ζ^{2k+1} moyennant la forme canonique $\xi x^2 - \eta y^2$.

A propos de l'équation $\xi x^2 - \eta y^2 = \zeta^{2k+1}$, il est connu, d'après la théorie des formes quadratiques, que le produit $\xi\eta$ doit être un résidu quadratique de ζ^{2k+1}, et partant, de ζ. L'auteur démontre finalement que, s'il existe une solution ξ^k, η^k de l'équation $\xi x^2 - \eta y^2 = \zeta^{2k+1}$, (ξ^k, η^k) doit être la solution minimale absolue parmi l'infinité de solutions représentant ζ^{2k+1} par cette forme. Ainsi le critère de l'auteur réduit le problème de Fermat à la détermination d'une méthode donnant la solution minimale absolue pour tout nombre impair ζ^{2k+1} représentable par une certaine forme canonique, quadratique binaire $(\zeta, -\eta)$ pour laquelle le produit $\xi\eta$ est un résidu quadratique de ζ, où x et y désignent toujours deux entiers positifs premiers entre eux et premiers respectivement, avec η et ξ. *A. Gloden* (Luxembourg)

Postnikova, L. P. 5782

Distribution of solutions of the congruence

$$x^2 + y^2 \equiv 1 \pmod{p^n}.$$

(Russian)

Mat. Sb. (*N.S.*) **65 (107)** (1964), 228–238.

Let p be a prime >3, n any natural number ≥ 13, and let $A(T, T_1)$ denote the number of solutions of the congruence $x^2 + y^2 \equiv 1 \pmod{p^n}$ such that $y \not\equiv \pm 1 \pmod{p}$, $0 \leq x \leq T$, $0 \leq y \leq T_1$. It is proved that for $1 \leq T \leq p^n$ and $p^{(4n+12)/6} \leq T_1 \leq p^n$

$$A(T, T_1) - TT_1 p^{-n-1}\{p - 2 - (-1)^{(p-1)/2}\} \ll e^{7n \log^2 n} T_1^{1-1/(84n^2 \log 3n)}.$$

The proof is a combination of I. M. Vinogradov's method with an elementary form of p-adic analysis, no knowledge of the latter being presupposed.

{There are plenty of misprints and some minor inaccuracies such as $12(n-1)^2 \geq 15n^2$ on p. 236, but they can be eliminated. A reference to Vinogradov's theorem [*Selected works* (Russian), p. 369, Izdat. Akad. Nauk SSSR, Moscow, 1952; MR **14**, 610] (where there are puzzling misprints) should be replaced by one to his original paper [Izv. Akad. Nauk SSSR Ser. Mat. **14** (1950), 199–214, p. 209; MR **12**, 161].} *E. Fogels* (Riga)

Rumsey, Howard, Jr.; Posner, Edward C. 5783

On a class of exponential equations.

Proc. Amer. Math. Soc. **15** (1964), 974–978.

The purpose of the paper is the proof of the following theorem. Let a be an odd integer or $a=2$, and let q_s $(1 \leq s \leq j)$ and r_t $(1 \leq t \leq k)$ be $j+k$ distinct primes, all prime to a. Then the equation $a^x = B + C$ $(B = q_1^{y_1} \cdots q_j^{y_j}$, $C = r_1^{z_1} \cdots r_k^{z_k})$ has only a finite number of solutions in non-negative integers x; $y_1, \cdots, y_j$; $z_1, \cdots, z_k$. All such solutions may be found in a finite number of steps. The fact that the number of solutions is finite follows from a more general statement in Gel'fond [*Transcendental and algebraic numbers* (Russian), GITTL, Moscow, 1952; MR **15**, 292; English transl., p. 37, Dover, New York, 1960; MR **22** #2598]. The fact that all solutions may be found constructively seems new. The proof is based on the factorization of a^{2x} in the field $R((-BC)^{1/2})$ (R is the field of rationals) and follows readily from the following lemma. Let D be a positive integer, H an algebraic integer in $R((-D)^{1/2})$, not a unit, u a unit in $R((-D)^{1/2})$ and $(p_1, p_2, \cdots, p_m)$ a fixed set of rational primes, all relatively prime to H. Then there exist effectively computable constants $X_1, \cdots, X_m$ such that $x_i \geq X_i$ $(1 \leq i \leq m)$ implies that $uH^r - \bar{u}\bar{H}^r = p_1^{x_1} p_2^{x_2} \cdots p_m^{x_m}(-D)^{1/2}$ has no solutions in non-negative integers r; $x_1, \cdots, x_m$. The proof of the lemma is obtained by considering separately the three particular cases $u = \pm 1$; $u = \pm i$, $D = 1$; $u = \frac{1}{2}(\pm 1 \pm i3^{1/2})$, $D = 3$.

Periodische Jacobische Algorithmen für eine unendliche Klasse algebraischer Irrationalzahlen vom Grade n und einige unendliche Klassen kubischer Irrationalzahlen.

J. Reine Angew. Math. **214/215** (1964), 76–83.

In three recent papers [same J. **212** (1963/64), 31–38; MR **27** #5727; ibid. **213** (1963/64), 137–146; MR **29** #2434; Math. Nachr. (to appear)] the author studied periodic continued fractions for special nth roots. The present paper contains the following new results. (1) Let D, d, n be integers such that $n\geq 3$, $d|D$, $n-1\leq d\leq D/(n-1)$, and let $\omega=\sqrt[n]{(D^n+dD)}$, $f_s=f_s(\omega, D)=\sum_{i=0}^{s}\binom{n-1+i-s}{i}\omega^{s-i}D^i$ $(s=1,\ 2,\ \cdots,\ n-1)$, $f_0=f_0(\omega, D)=1$. Then the system of $n-1$ numbers f_1/d, f_2/d^2, $\cdots, f_{n-1}/d^{n-1}$ produces a pure periodic Jacobi algorithm with a primitive period of length n if $D\neq d^{n-1}$ and of length 1 if $D=d^{n-1}$. Explicit expressions for the form of this period are given here. (2) Let d, D be integers, $d|D$. If $\omega=\sqrt[3]{(D^3+dD)}$, then the numbers $(\omega+2D)/d$, $(\omega^2+\omega D+D^2)/d^2$ form a pure periodic Jacobi algorithm with a primitive period of length 3 or 1 according as $D\neq d^2$ or $D=d^2$, respectively. The form of the primitive period is given in this paper. *E. Frank* (Chicago, Ill.)

Bernstein, Leon 5787

Periodische Kettenbrüche beliebiger Periodenlänge.

Math. Z. **86** (1964), 128–135.

The following theorems are proved concerning the explicit form of two periodic continued fractions of arbitrarily prescribed length. Each continued fraction represents a given binomial quadratic surd. (1) Let a and n be integers, $N=\frac{1}{2}(n-1)$, and the integer

$$x_n=2^{-n+1}\sum_{i=0}^{N}\binom{n}{2i+1}a^{n-2i-1}(a^2+4)^i,\qquad n=1,2,\cdots.$$

Let d be an integer such that (A) $D=\frac{1}{2}(a+d\cdot x_{n+1})$ is integral. Then $\sqrt{(D^2+1+d\cdot x_n)}=[D,\overline{a,a,\cdots,a,2D}]$, a continued fraction with period of length $n+1$. A number d of the type required by (A) does not exist if a is odd and simultaneously $n+1$ is divisible by 3. (2) Let a and b be integers, $a|b$, and the integer

$$f_n(ab)=2^{-2n-1}\sum_{i=0}^{n}\binom{2n+2}{2i+1}(ab)^{n-i}(ab+4)^i,$$

$$n=0,1,\cdots.$$

Let d be an integer such that (B) $D=\frac{1}{2}[b+adf_n(ab)]$ is integral. Then

$$\sqrt{(D^2+2D:a-df_{n-1}(ab))}=[D,\overline{a,b,a,b,\cdots,a,b,a,2D}],$$

a continued fraction with period of length $2n+2$. A number d of the type required by (B) does not exist if b is odd and simultaneously $n+1$ is divisible by 3.

It is shown that, for any irrational number θ and for any prime P, at least one of the numbers

$$P^2\theta,\ \theta,\ \theta+1/P,\ \cdots,\ \theta+(P-1)/P$$

has a simple continued fraction whose partial denominators a_n satisfy $a_n>P-2$ for infinitely many indices n.

W. T. Scott (Tempe, Ariz.)

Šalát, Tibor 5789

Eine metrische Eigenschaft der Cantorschen Entwicklungen der reellen Zahlen und Irrationalitätskriterien. (Russian summary)

Czechoslovak Math. J. **14** (89) (1964), 254–266.

Let $\{q_n\}$ be an infinite sequence of integers larger than 1, and for each $x\in[0, 1)$ let

$$x=\sum_{n=1}^{\infty}\frac{\varepsilon_n(x)}{q_1\cdots q_n}$$

be the Cantor expansion of x relative to $\{q_n\}$, so that $\varepsilon_n(x)$ is an integer such that $0\leq\varepsilon_n(x)\leq q_n-1$ always, and $\varepsilon_n(x)<q_n-1$ for infinitely many n. It is shown that, for almost all x, $\liminf\varepsilon_n(x)/q_n=0$, and that if $\limsup q_n=\infty$, then for almost all x, the set of limit points of $\{\varepsilon_n(x)/q_n\}$ is the whole interval $[0, 1]$. The proofs use the notion of a homogeneous set and the following condition for homogeneity. Let $Q_n=q_1\cdots q_n$, and let i_n^k be the interval $[k/Q_n, (k+1)/Q_n)$ for $0\leq k<Q_n$. Let B be a measurable set in $[0, 1)$. Then B is homogeneous if $\operatorname{mes}(B\cap i_n^k)=\operatorname{mes}(B\cap i_n^{k'})$ for all k, $k'<Q_n$.

As an application, the author considers four sufficient conditions for the irrationality of x, in terms of the Cantor expansion of x, given by A. Oppenheim [Amer. Math. Monthly **61** (1954), 235–241; MR **15**, 781] and P. H. Diananda and A. Oppenheim [ibid. **62** (1955), 222–225; MR **16**, 908]. (For example, x is irrational if 1 is a limit point of $\{\varepsilon_n/q_n\}$.) He shows, for each of three of the four cases, that the condition is satisfied by almost all x if $\{q_n\}$ has one kind of behavior, and by almost no x otherwise. The remaining condition is shown to hold for almost all x under certain circumstances.

Freiman, G. A. 5790

Inverse problems in additive number theory. VIII. On a conjecture of P. Erdős. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 3 (40), 156–169.

The present paper depends primarily on Part VII of the series [same Izv. **1962**, no. 6 (31), 131–144; MR **26** #2420]. It gives an affirmative response to a conjecture of P. Erdős contained in one of his problem collections [Monographies de L'Enseignement Mathématique, No. 6, pp. 81–135; L'Enseignement Mathématique, Université, Genève, 1963; MR **28** #2070]: Let A be a set of non-negative numbers arranged as an increasing sequence, $a_0=0$, $a_i<a_{i+1}$. Let $A(x)$ be the number of elements of A which are less than or equal to x; let $A_2(x)$ be the similar function for $A+A$. Suppose $\lim_{x\to\infty}A(x)/x=0$, then $\delta=\limsup_{x\to\infty}A_2(x)/A(x)\geq 3$. The proof is by the method of trigonometrical sums over parallelepipeds defined by vectors of partial sequences

from A. Several other theorems are obtained of which the following (Theorem 4) may be given without further definitions: If $\delta \leqq 4.1$ and $\lim_{x\to\infty} A(x)/x = 0$, there are infinitely many $a_i \in A$ such that $2a_i < a_{i+1}$.

J. D. Swift (Los Angeles, Calif.)

Freiman, G. A. 5791

On the addition of finite sets. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1038–1041.

This paper is primarily concerned with the structure of sets $K = \{a_0, a_1, \cdots, a_{k-1}\}$ of integers such that the sum set $K+K$ of numbers of the form $a_i + a_j$ (each representable number being counted once only) has comparatively few members. The author shows that such sets are obtained by a linear map from the integral points in a convex set in affine space of comparatively small dimension. More precisely, he proves the following (Theorem 1). Suppose that the number T of elements of $K+K$ satisfies $T < Ck$, where $C \geqq 2$, and suppose that k is sufficiently large. Then there exists an integer $n \leqq [C-1]$, a homomorphism φ of the additive group Z_n of integral points in n dimensions into the corresponding group Z_1 in one dimension and a convex subset D of n-dimensional space such that (1) $K \subset (D \cap Z_n)\varphi$; (2) the sets $D \cap Z_n$ and $(D \cap Z_n)\varphi$ are "isomorphic up to the first degree", i.e., φ is an isomorphism and induces an isomorphism in the sets of sums of pairs of elements; (3) the number of elements in $D \cap Z_n$ is at most $c_1 k$, where $c_1 = c_1(C)$.

The proof is rather complicated and depends essentially on earlier work of the author [Izv. Vysš. Učebn. Zaved. Matematika **1962**, no. 3 (28), 151–157; MR **27** #2464; ibid. **1964**, no. 6 (43), 168–178; see also #5790 above].

In conclusion, the author states a similar result about sets D in n-dimensional euclidean space which satisfy an inequality $\mu^*(2D) \leqq C\mu^*(D)$, where μ^* is the outer Lebesgue measure and C is a constant; it is mentioned that there are similar results for lower asymptotic density of sequences of integers.

J. W. S. Cassels (Cambridge, England)

Mullender, P. 5792

Some remarks on a method of Mordell in the Geometry of Numbers.

Acta Arith. **9** (1964), 301–304.

The "method" of the title leads to an inequality connecting the critical determinant of an n-dimensional star body with that of a related $(n-1)$-dimensional star body. Several authors [see, e.g., C. G. Lekkerkerker, J. Reine Angew. Math. **206** (1961), 20–25; MR **26** #2401] have attempted to analyse the underlying principles of the method; the present paper seeks to elucidate it further.

Let $F(x)$, $G(x)$ be the distance functions of two star bodies K_F, K_G of finite type in n-dimensional Euclidean space, X. Suppose that K_F possesses a group Ω of automorphs such that the adjoint of an automorph of K_F is an automorph of K_G; that is, there is a group of non-singular matrices, A, such that $F(Ax) = F(x)$, $G(\tilde{A}x) = G(x)$ for all $x \in X$, where $\tilde{A}$ is the transposed inverse of A. The main theorem reads as follows. Suppose that there are in X a k-dimensional linear sub-space R and an $(n-k)$-dimensional linear sub-space S, perpendicular to R, such that (a) the k-dimensional and $(n-k)$-dimensional star bodies $R \cap K_F$ and $S \cap K_G$ are of finite type in R, S, respectively; (b) to any k-dimensional linear sub-space R' of X such that the k-dimensional star body $R' \cap K_F$ is of finite type in R' there corresponds an automorph of K_F in Ω transforming R' into R. Then, for $k = n-1$,

$$(\Delta_{K_F})^k \geq \left(\frac{\Delta_{R\cap K_F}}{\Delta_{S\cap K_G}}\right)^n \cdot (\Delta_{K_G})^{n-k},$$

where Δ_{K_F} denotes the critical determinant of K_F, etc.

The integer k is introduced in order to indicate possible generalizations of the theorem. However, it is not easy to see what the right generalization should be, and it may be a difficult problem to solve, if indeed there is a solution at all. For an example of a particular case in which the method can be carried further, see a paper by the reviewer [Mathematika **2** (1955), 132–140; MR **17**, 1060].

The number of representations of a number as a sum of two squares.

Amer. Math. Monthly **70** (1963), 1081–1082.

The authors obtain what they call an apparently new expression for $r_2(n)$ (the number of representations of n as sum of two squares) in the form

$$r_2(n) = 4 \prod \left\{\left[\frac{\alpha+2}{2}\right] + (-1)^{[p/2]}\left[\frac{\alpha+1}{2}\right]\right\},$$

where $n = 2^\lambda \prod p^\alpha$ is the canonical factorization of n. {Reviewer's remark: This is the same as (16.9.5) in Hardy and Wright's *An introduction to the theory of numbers* [fourth edition, Clarendon, Oxford, 1960].}

M. V. Subbarao (Edmonton, Alta.)

Horadam, E. M. 5795

Ramanujan's sum for generalised integers.

Duke Math. J. **31** (1964), 697–702.

Let $\{p\}$ be a sequence of real numbers (generalized primes) such that $0 < 1 < p_1 < p_2 < \cdots$. Form the set $\{l\}$ of all p-products $p_1^{v_1} p_2^{v_2} \cdots$, where the v_i are integers $\geqq 0$, of which all but a finite number are 0. These numbers are called generalized integers; it is assumed that no two are equal if their v's are different. Also the l's are numbered so that $0 < 1 < l_2 < l_3 < \cdots$. Ramanujan's sum for $\{l\}$ is defined by means of

$$c(l_n, l_r) = \sum_{d \mid (l_n, l_r)} \mu(l_r/d) d.$$

More generally the author defines

$$c_k(l_n, l_r) = \sum_{\substack{d \mid l_r \\ d^k \mid l_n}} \mu(l_r/d)d^k,$$

thus generalizing the function

$$c_k(n, r) = \sum_{(x, r^k)_k = 1} e(nx, r^k)$$

introduced by E. Cohen [same J. **22** (1955), 543–550; MR **17**, 238]. The present paper generalizes a number of results concerning $c_k(n, r)$, and also some properties of the class E_k of k-even functions, that is, functions $f(l_n, l_r)$ such that

$$f(l_n, l_r) = f((l_n, l_r^k)_k, l_r).$$

The class E_k for functions of integers has been studied by P. J. McCarthy [J. Reine Angew. Math. **203** (1960), 55–63; MR **22** #2574]. For example, it is proved that if $f(l_n, l_r) \in E_k$, then

$$f(l_n, l_r) = \sum_{d \mid l_r} \alpha(d) c_k(l_n, d),$$

where

$$\alpha(d) = \frac{1}{l_r^k} \sum_{\delta \mid l_r} f\left[\left(\frac{l_r}{\delta}\right)^k, l_r\right] c_k\left[\left(\frac{l_r}{d}\right)^k, \delta\right].$$

L. Carlitz (Durham, N.C.)

Carlitz, L. 5796

Extended Bernoulli and Eulerian numbers.

Duke Math. J. **31** (1964), 667–689.

Extensions of Bernoulli and Eulerian numbers and polynomials are studied by the author. The extended Bernoulli numbers $\beta(n)$ and polynomials $\beta(n, z)$ are defined by

$$\frac{\log \zeta(s)}{\zeta(s) - 1} = \sum_{n=1}^{\infty} \beta(n)/n^s, \qquad \zeta(s) = \sum_{n=1}^{\infty} 1/n^s,$$

$$\frac{(\zeta(s))^z \log \zeta(s)}{\zeta(s) - 1} = \sum_{n=1}^{\infty} \frac{\beta(n, z)}{n^s},$$

respectively, while the extended Eulerian numbers $H(n, \lambda)$ and polynomials $H(n, \lambda, z)$ are defined by

$$\frac{1 - \lambda}{\zeta(s) - \lambda} = \sum_{n=1}^{\infty} \frac{H(n, \lambda)}{n^s},$$

$$\frac{(1 - \lambda)(\zeta(s))^z}{\zeta(s) - \lambda} = \sum_{n=1}^{\infty} \frac{H(n, \lambda, z)}{n^s}, \qquad \lambda \neq 1.$$

A number of algebraic properties of these numbers and polynomials are discussed, most of which are generalizations of the corresponding properties of the Bernoulli and Eulerian numbers and polynomials. Expressions for $\beta(n)$, $H(n, z)$ are obtained for special values of n, and multiplication theorems are proved, e.g.,

$$\sum_{j=0}^{m-1} \beta\left(n, mh, z + \frac{j}{m}\right) = m\beta(n, h, mz),$$

where

$$\frac{h \log \zeta(s)}{(\zeta(s))^h - 1} (\zeta(s))^{hz} = \sum_{n=1}^{\infty} \frac{\beta(n, h, z)}{n^s}, \qquad h \neq 0.$$

On a problem about the Epstein zeta-function.

Proc. Cambridge Philos. Soc. **60** (1964), 855–875.

Let $h(m, n) = \alpha m^2 + 2\delta mn + \beta n^2$, where $\alpha\beta - \delta^2 = 1$, an write $Q(m, n) = 2 \cdot 3^{-1/2}(m^2 + mn + n^2)$ and

$$Z_h(s) = \sum \sum \{h(m, n)\}^{-s},$$

the summation being over all integers m, n with th exception of $m = n = 0$. The series converges for Re $s > 1$ The reviewer [Proc. Glasgow Math. Assoc. **1** (1953) 149–158; MR **15**, 507], Cassels [ibid. **4** (1959), 73–80 MR **22** #7975], the author [#5798a below] and Dianand [#5798b below] proved that $Z_h(s) \geq Z_Q(s)$ for real $s >$ where the sign of equality is needed only if h is equivalen to Q. The author considers the three-dimensional analogu of this problem and makes the conjecture that, for $s >$ $Z_f(s) \geq Z_R(s)$, strict inequality holding except when f i equivalent to R. Here

$$f(m, n, p) = am^2 + bn^2 + cp^2 + 2rnp + 2spm + 2tmn,$$

the determinant being $\frac{1}{2}$, and

$$R(m, n, p) = m^2 + n^2 + p^2 + mp + np.$$

The zeta-functions $Z_f(s)$ and $Z_R(s)$ are defined similarl by infinite series that are absolutely convergent fo Re $s > \frac{3}{2}$. This conjecture he is unable to prove, but b very complicated analysis he shows that the form R give a local minimum for $Z_f(s)$. *R. A. Rankin* (Glasgow

Ennola, Veikko 5798

A lemma about the Epstein zeta-function.

Proc. Glasgow Math. Assoc. **6**, 198–201 (1964).

Diananda, P. H. 5798

Notes on two lemmas concerning the Epstein zeta function.

Proc. Glasgow Math. Assoc. **6**, 202–204 (1964).

The reviewer's paper [same Proc. **4** (1959), 73–80; MR **2** #7975] contained a silly blunder which apparentl vitiated the whole argument. Ennola notes the blunder an shows that it can be rectified by a more elaborate argu ment on the same general lines as the original on Diananda shows that the proof of the reviewer's resul can be considerably simplified.

J. W. S. Cassels (Cambridge, Englan

Grosswald, E. 579

Considerations concerning the complex roots of Rie mann's zeta-function.

Publ. Math. Debrecen **10** (1963), 157–170.

The results are too elaborate to quote in detail, but th general idea is to connect the upper bound θ of the re parts of the zeros of $\zeta(s)$ with the behaviour of functio such as

$$F(x) = \sum_{n=1}^{\infty} \frac{(-x)^n}{\zeta(2n)\varphi(n)}, \qquad \Psi(u) = \sum_{n=2}^{\infty} \frac{u^{n-2}}{\zeta(\frac{1}{2}n)\varphi(\frac{1}{2}n)}.$$

M. Riesz proved that, when $\varphi(s) = \Gamma(s)$, a necessary an sufficient condition for the Riemann hypothesis ($\theta = \frac{1}{2}$) that $F(x) = O(x^\alpha)$ as $x \to \infty$, for every fixed $\alpha > \frac{1}{4}$. Theorem extends results of this type to general classes Φ and of functions

into a different shape. Theorem 4 asserts that, if, for some φ in Φ, the integral function $\Psi(u)$ is of order $<\frac{1}{2}$ (or of order $\frac{1}{2}$ and minimal type), then $\theta=1$. Another type of result gives analogues, for various arithmetical functions $R_1(x)$, of the theorem that $R(x)=\psi(x)-x$ is $O(x^\alpha)$ if $\alpha>\theta$ but not if $\alpha<\theta$. (This seems to be the intention of Theorem 3 and the succeeding remarks, though the italicized statement of the theorem appears to be nothing more than a list of definitions.) [The basic assumptions about $\varphi(s)$ are stated in a form that does not seem to accord with what is assumed in proofs. Thus, on p. 158, the hypothesis (I) is stated only for fixed σ and varying t, and (II) for fixed t and varying σ; but any normal application of Cauchy's theorem, such as the one on p. 162, presumes uniform estimates of the integrand. There are other inaccuracies of presentation.]

A. E. Ingham (Cambridge, England)

Nevanlinna, Veikko 5800

Über die elementaren Beweise der Primzahlsätze und deren äquivalente Fassungen.

Ann. Acad. Sci. Fenn. Ser. A I No. 343 (1964), 52 *pp.*

The prime number theorem (PNT) asserts that

$$\text{(I)}\qquad \pi(x)\sim x/\log x,\qquad x\to\infty,$$

where $\pi(x)$ is the number of primes $p\leq x$. (I) is known to be equivalent to the following assertions:

$$\text{(II)}\qquad \vartheta(x)\sim x,\qquad x\to\infty,$$

where $\vartheta(x)$ denotes the sum $\vartheta(x)=\sum_{p\leq x}\log p$, and

$$\text{(III)}\qquad \psi(x)=\sum_{p^r\leq x}\log p=\sum_{n\leq x}\Lambda(n)\sim x,\qquad x\to\infty,$$

where the function $\Lambda(n)$ is defined as being $\log p$ when n is a prime p or one of its powers and 0 otherwise [e.g., A. E. Ingham, *The distribution of prime numbers*, p. 13, Cambridge Univ. Press, London, 1932].

All previous proofs up to 1948 have been by "transcendental" arguments involving some appeal to the theory of functions of a complex variable, but then A. Selberg and P. Erdős [see, e.g., J. G. van der Corput, Math. Centrum Amsterdam Scriptum No. 1 (1948); MR **10**, 597] succeeded in producing an elementary proof of the PNT, not depending on analytical ideas remote from the problem itself. In various versions elementary proofs were given by A. Selberg [Ann. of Math. (2) **50** (1949), 305–313; MR **10**, 595], P. Erdős [Proc. Nat. Acad. Sci. U.S.A. **35** (1949), 374–384; MR **10**, 595], and others.

The purpose of this paper is essentially to give a simple elementary proof of the PNT and to deduce its equivalent formulas while exhibiting the parallelism running through the proofs. The starting point in the first chapter of this paper is Selberg's asymptotic formula:

$$\text{(a)}\qquad \rho(x)\log x+\int_{1-}^{x+}\rho(x/t)\,d\psi(t)=O(x)\qquad(\rho(x)=\psi(x)-x),$$

which is effected to this form from Selberg's original formula through application of the method of T. Tatuzawa and K. Iseki [Proc. Japan Acad. **27** (1951), 340–342; MR **13**, 725]. The PNT is then deduced first by eliminating the differential $d\psi$ to get Selberg's inequality:

$$\text{(b)}\qquad |\rho(x)|\log^2 x\leq 2\int_2^x|\rho(x/t)|\log t\,dt+O(x\log x).$$

After the substitution of $r(x)=e^{-x}\rho(e^x)=e^{-x}\psi(e^x)-1$ the author deduces from this inequality by elementary arguments $r(x)=o(1)$, which is equivalent to the PNT [Soc. Sci. Fenn. Comment. Phys.-Math. **27** (1962), no. 3; MR **26** #2416].

The second chapter starts with the following notations:

$$\varepsilon(x)=\int_{1-}^{x+}d\psi(t)/t-\log x+C,$$

$$M(x)=\sum_{n\leq x}\mu(n),$$

$$B(x)=\sum_{n\leq x}\mu(n)/n=\int_{1-}^{x+}dM(t)/t,$$

where C is the Euler constant, and μ denotes the Möbius function. Then it is shown that as $x\to\infty$

$$\text{(IV)}\qquad \varepsilon(x)=o(1),$$

$$\text{(V)}\qquad M(x)=o(x),$$

$$\text{(VI)}\qquad B(x)=o(1)$$

are each equivalent to the formula (III). Selberg's asymptotic formula is derived for the function $\varepsilon(x)$, and through the use of the ideas of Pitt [*Tauberian theorems*, Oxford Univ. Press, London, 1958; MR **21** #5109] and Selberg, a new variant of Selberg's proof is given. The equivalence of (III), (IV), (V), and (VI) is proved by showing the logical relations among them. It is shown that if $\rho(x)$ in (a) and (b) is replaced by $M(x)$ or $B(x)$, then an almost complete analogy for the asymptotic expression and inequality of Selberg holds.

In the third chapter the author deduces the PNT for arithmetical progressions corresponding to (I), (II), and (III), which was first proved in an elementary way by Selberg [Canad. J. Math. **2** (1950), 66–78; MR **11**, 419]. Here again, the lemma of Tatuzawa and Iseki is used to derive Selberg's asymptotic formula and inequality. Then the method in the chapter is carried out, resulting in the almost complete analogy with the first chapter. Finally, an elementary proof is given of Dirichlet's theorem about primes in arithmetic progressions [cf., e.g., A. Selberg, Ann. of Math. (2) **50** (1949), 297–304; MR **10**, 595].

Breusch, Robert 5801

An asymptotic formula for primes of the form $4n+1$.

Michigan Math. J. **11** (1964), 311–315.

By an elementary method (based on factoring of the number $\prod(r^2+s^2)$, $1\leq r\leq n$, $1\leq s\leq n$) the author proves the asymptotic formula

$$\sum_{p\leq x}p^{-1}\log p=\tfrac{1}{2}\log x+O(1),$$

where p runs through the primes $4n+1$ (or $4n-1$). The author notes that a similar proof can still be given for progressions $6n\pm1$.

E. Fogels (Riga)

Fogels, E. 5802

On the abstract theory of primes. I.

Acta Arith. **10** (1964/65), 137–182.

The theory in question arises from replacing the positive integers by a countable multiplicative semigroup G of real numbers $a\geq1$ with some asymptotic distribution law.

The role of the primes is taken over by the generators of G. To get the equivalent of arithmetic progressions, G is split into classes H_i $(i=1,\cdots,h)$ forming a group K under the multiplication given by: If $a \in H_i$, $a' \in H_j$, then $aa' \in H_k$ with $k=k(i,j)$. The class H_i corresponds to an arithmetic progression.

The author's aim is to get, under suitable assumptions, an upper estimate for the smallest generator of G in H_i, valid simultaneously for all i. A parameter D is introduced corresponding to the common difference in an arithmetic progression, and it is supposed that $D>3$, $1 \leq h \leq D^{c_0}$, $c_0>0$. The asymptotic distribution law which is assumed is $\sum 1 = \alpha x + O(D^{c_1}x^{1-\theta})$ for large x, where the summation is over all $a \in H_i$ such that $a \leq x$, and $\alpha = D^l$; the constants l, c_1, θ do not depend on i.

For even h let K_j be any subgroup of K with index 2. Then it is shown that

$$\lim_{x\to\infty}\Big(\sum_{a\in K, a\leq x} a^{-1} - \sum_{a\in K_j, a\leq x} a^{-1}\Big) = C_j = C_j(D).$$

Now the main theorem is: (i) If $\theta > \frac{1}{2}$, there is a $c>0$ such that for any $x \geq 1$, H_i has a generator in the interval (x, xD^c). For odd h this holds also if $\theta \leq \frac{1}{2}$. (ii) For even h and $\theta \leq \frac{1}{2}$, the conclusion of (i) holds if there is a $c_2>0$ such that $C_j > D^{-c_2}$ for any j (in this case c also depends on c_2). (iii) Let $\pi(x, H_i)$ be the number of generators (generalized primes) in H_i not exceeding x. Then constants c_3, c_4 exist such that $\pi(x, H_i) > D^{-c_3}x/\log x$ for $x > D^{c_4}$.

The proof, running to over twenty-five lemmas, is long, involved, and not easy to follow. The method is analytical in nature and employs the following zeta-functions and L-series: $\zeta(s,H) = \sum_{a\in H} a^{-s}$, $\zeta(s,\chi) = \sum_a \chi(a)a^{-s}$ (χ is a character of the group K and $\chi(a)$ is $\chi(H)$ for all $a \in H$). One then has, as for the ordinary case, $\zeta(s,\chi) = \prod_b [1-\chi(b)b^{-s}]^{-1}$, where b runs over all generators of G.

Partitions with equal products.

Proc. Amer. Math. Soc. **15** (1964), 987–990.

The author proves the following theorem: If k is an integer ≥ 3, there exists an $N(k)$ such that every $n \geq N(k)$ can be partitioned into k parts in $(k-1)$ different ways so that the products of the integers in these $(k-1)$ partitions are equal. What is more, the integers which occur in all these partitions are pairwise different.

A new method in probabilistic number theory. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 307–364.

This paper is a continuation of the author's previous investigations on topological methods in number theory [Učen. Zap. Elabužsk. Gos. Ped. Inst. **8** (1960), 3–[illegible]; Izv. Vysš. Učebn. Zaved. Matematika **1961**, no. 1 (2[illegible]), 119–129; MR **27** #6249; ibid. **1961**, no. 3 (22), 66–[illegible]; MR **28** #77; ibid. **1963**, no. 5 (36), 71–88; MR **28** #78].

The ring S of integer rational numbers may be to[pologized] by means of the topology for which the princi[pal] ideals constitute a neighbourhood base of 0. By co[m]pletion of S we get a compact topological ring $\mathfrak{S}$; t[he] elements of $\mathfrak{S}$ are called polyadic numbers. The set $\mathfrak{S}$ [is] also a bicompact topological group; accordingly, th[ere] exists a normed Haar measure μ on $\mathfrak{S}$. The completion [of] μ is a probabilistic measure P.

The author gives a number of applications of the theo[ry] of measure P and the corresponding integral calculus [to] the value distribution theory of the arithmetical functi[ons] and to the calculation of their means.

In particular, the author obtains some results on t[he] almost periodicity of the arithmetical functions due [to] Erdős, Hartman, Kac, van Kampen and Wintner [K[ac], van Kampen and Wintner, Amer. J. Math. **62** (194[0]), 107–114; MR **1**, 203; van Kampen and Wintner, ibid. [62] (1940), 613–626; MR **2**, 41; van Kampen, ibid. **62** (194[0]), 627–634; MR **2**, 41; Erdős and Wintner, ibid. **62** (194[0]), 635–645; MR **2**, 41; Hartman and Wintner, ibid. [62] (1940), 753–758; MR **2**, 41; Wintner, ibid. **67** (194[5]), 173–193; MR **6**, 260; Wintner, ibid. **67** (1945), 481–4[?]; MR **7**, 147]. From Kolmogorov's three series criterion [for] the convergence of the series of the independent rand[om] variables he deduces the Erdős theorem [J. London Ma[th.] Soc. **13** (1938), 119–127] on the sufficient condition [for] the existence of the asymptotic distribution law of addit[ive] number-theoretic functions. He also proves a theorem [of] Rényi [Acad. Serbe Sci. Publ. Inst. Math. 8 (1955), 1[?]–162; MR **17**, 944], a theorem of Hardy and Ramanu[jan] [Quart. J. Pure Appl. Math. 48 (1917), 76–92], and so[me] results of the reviewer [*Probabilistic methods in the the[ory] of numbers* (Russian), Gosudarstv. Izdat. Politič. i Nau[č.] Lit. Litovsk. SSR, Vilna, 1959; MR **22** #A134; sec[ond] enlarged edition, 1962; MR **26** #3691].

J. Kubilius (Vilni[us])

Roth, K. F. 5[806]

Remark concerning integer sequences.

Acta Arith. **9** (1964), 257–260.

Let N be a positive integer, and let $\mathcal{N}$ be a set of disti[nct] positive integers not exceeding N. For each integer [q,] $0 < m \leq N$, and each residue class $h \pmod q$, denote [by] $\Phi_{q,h}(\mathcal{N}; m)$ the number of elements of $\mathcal{N}$ not exceed[ing] m and in the residue class, and by $\Phi_{q,h}^*(\mathcal{N}; m)$ t[he] corresponding "expectation",

$$\Phi_{q,h}^*(\mathcal{N}; m) = \eta\Phi_{q,h}(\mathcal{J}; m),$$

where $\mathcal{J}$ is the set $\{1,\cdots,N\}$ and

$$\eta = N^{-1}\sum_{\substack{n\leq N\\ n\in\mathcal{N}}} 1.$$

For each m and q, define

$$V_q(m) = \sum_{h=1}^{q}\{\Phi_{q,h}(\mathcal{N}; m) - \Phi_{q,h}^*(\mathcal{N}; m)\}^2.$$

It is shown that for every positive integer Q,

$$\sum_{q=1}^{Q} q^{-1}\sum_{m=1}^{N} V_q(m) + Q\sum_{q=1}^{Q} V_q(N) > c\eta(1-\eta)Q^2N,$$

where c is an absolute constant. Qualitatively and crudely speaking, this theorem shows that unless a sequence of integers has density nearly 0 or 1, its elements cannot be too evenly distributed simultaneously among all residue classes. *W. J. LeVeque* (Ann Arbor, Mich.)

Kesten, H. 5807

The discrepancy of random sequences $\{kx\}$.

Acta Arith. **10** (1964/65), 183–213.

For $0 \leq a \leq b \leq 1$, let

$$f(\xi; a, b) = 1 \quad \text{if } a \leq \xi \leq b,$$
$$= 0 \quad \text{if } 0 \leq \xi < a \text{ or } b < \xi \leq 1,$$
$$f(\xi+1; a, b) = f(\xi; a, b),$$

and for $1 < b \leq 1+a$, put

$$f(\xi; a, b) = f(\xi; a, 1) + f(\xi; 0, b-1).$$

For each real x, let

$$D_N(x) = N^{-1} \sup_{0 \leq a \leq b \leq 1+a} \left| \sum_{k=1}^{N} f(kx; a, b) - N(b-a) \right|.$$

The principal result of this deep paper is that for every fixed $\varepsilon > 0$,

$$\lim_{N\to\infty} \operatorname{mes}\left\{ x \in [0;1] : \left| \frac{N D_N(x)}{\log N \log\log N} - \frac{2}{\pi^2} \right| > \varepsilon \right\} = 0.$$

The proof depends on a fairly explicit, but rather complicated, connection between $D_N(x)$ and the continued fraction expansion of x.

K. Mahler (Canberra)

Ramanujam, C. P. 5811

Sums of m-th powers in p-adic rings.

Mathematika **10** (1963), 137–146.

Let K be an algebraic number field, and m a positive integer. Siegel has conjectured that there is a $G(m)$ such that every totally positive integer of large enough norm that is a sum of mth powers of integers of K is a sum of at most $G(m)$ such mth powers. The point is that $G(m)$ should be independent of the particular field K. The reviewer [Proc. Cambridge Philos. Soc. **57** (1961), 449–459; MR **26** #1306] has shown that to prove Siegel's conjecture it is enough to deal with the $\mathfrak{p}$-adic analogue.

Suppose then that A is the ring of integers of a $\mathfrak{p}$-adic field, whose residue class field has p^f elements, and let $J_m(A)$ be the subring generated by mth powers of elements of A. The author proves that each element of $J_m(A)$ is a sum of at most $8m^5$ mth powers.

The author first analyses what $J_m(A)$ looks like in the unramified case; the proof of his theorem in this case is then natural. Next, by a device, he deals quite simply with the case where the residue class field is large ($p^f \geq m$). Finally, he forces through the case $p^f < m$; the details of this part are (unavoidably) rather messy.

The author's final estimate $8m^5$ for the number of variables necessary is surprisingly good, though by no means best possible. The reviewer has proved a similar (less precise but slightly more general) theorem [Acta Arith. **9** (1964), 169–176; MR **29** #3462].

Jakovlev, A. V. 5814

The immersion problem for fields. (Russian)

Dokl. Akad. Nauk SSSR **150** (1963), 1009–1011.

The author considers the problem of constructing the extension field K of a normal extension field k of a field k_0, where the Galois group $\mathfrak{G}$ of K over k_0 and the Galois group $\mathfrak{F}$ of k over k_0 lie in an exact sequence

$$1 \to \mathfrak{A} \to \mathfrak{G} \xrightarrow{\pi} \mathfrak{F} \to 1;$$

here $\mathfrak{A}$ is periodic of period n, π is the restriction map of Galois groups and k contains a primitive nth root of unity.

This problem is reduced to a group extension problem $0 \to C \to X \to \hat{\mathfrak{A}} \to 0$, where $\hat{\mathfrak{A}} = \mathrm{Hom}_z(\mathfrak{A}, C)$ and C is the multiplicative group of k. *S. Rubinstein* (Seattle, Wash.)

Lur'e, B. B. 5815

On the problem of imbedding with a kernel without center. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 1135–1138.

We are given a finite group G and a homomorphism φ of G onto the Galois group F of a normal field extension k/k_0. The problem of imbedding is to find a Galois algebra A over k_0 with Galois group G such that the subalgebra fixed by $B = \ker \varphi$ is k_0-isomorphic to k, and such that the automorphism induced by $g \in G$ on this subalgebra is isomorphic to that induced by $\varphi(g)$ on k.

The author makes a simple reduction of this problem when B has no center, essentially factoring G by the centralizer of B. He then combines this technique with results of Delone and Faddeev [Mat. Sb. (N.S.) **15** (**57**) (1944), 243–284; MR **6**, 200] to reduce the problem in several special cases (e.g., when B is meta-cyclic without center) to compatibility of G with k.

Kolchin, E. R. 5816

The notion of dimension in the theory of algebraic differential equations.

Bull. Amer. Math. Soc. **70** (1964), 570–573.

The author introduces a highly important measure of the size of the solution set of a system of algebraic (ordinary or partial) differential equations and announces some of its properties whose proofs and details will appear in a forthcoming book. This measure is a certain numerical polynomial $\omega_\mathfrak{p}$ in one indeterminate (in the sense [of] Zariski and Samuel) defined for every prime different[ial] polynomial ideal $\mathfrak{p}$; it is called the differential dimensi[on] polynomial of $\mathfrak{p}$ and is somewhat related to Hilber[t's] "characteristic function" for homogeneous polynom[ial] ideals. This polynomial contains more information abo[ut] $\mathfrak{p}$ than the differential dimension of $\mathfrak{p}$ which can be deriv[ed] from it easily. In particular, two distinct prime different[ial] ideals $\mathfrak{p}$, $\mathfrak{p}'$ with $\mathfrak{p} \subset \mathfrak{p}'$ have distinct differential dimensi[on] polynomials $\omega_\mathfrak{p}$, $\omega_{\mathfrak{p}'}$ with $\omega_\mathfrak{p} > \omega_{\mathfrak{p}'}$ with respect to a suitab[le] total ordering of these numerical polynomials. While [it] is only a birational invariant, several differential [bi]rational invariants can be derived from it, for examp[le] the typical differential dimension and the differential ty[pe] of $\mathfrak{p}$ which, in classical terminology, describe the numb[er] of arbitrary functions and the number of their variab[les] on which the solution of the corresponding syst[em] depends. *A. Jaeger* (Cincinnati, Oh[io])

ABSTRACT ALGEBRAIC GEOMETRY

Matsumura, Hideyuki; Monsky, Paul 58[20]

On the automorphisms of hypersurfaces.

J. Math. Kyoto Univ. **3** (1963/64), 347–361.

The authors consider a hypersurface $H_{n,d}$ of degree d [in] the projective space P_{n+1} of dimension $n+1$ and the gro[up] $\mathrm{Aut}(H_{n,d})$ of all biregular transformations of $H_{n,d}$ o[nto] itself. The main results are as follows. (1) If $H_{n,d}$ is no[n]singular and $n \geq 2$, $d \geq 3$, then $\mathrm{Aut}(H_{n,d})$ is finite except [in] the case $n = 2$, $d = 4$. (2) If $H_{n,d}$ is generic over the pri[me] field and if $n \geq 2$, $d \geq 3$, then $\mathrm{Aut}(H_{n,d})$ is trivial except [in] the case that the ground field has characteristic $p > 0$ a[nd]

$n=2$, $d=4$. The proofs use a theorem of Severi and Lefschetz, according to which any positive divisor on a non-singular $H_{n,d}$ is cut out by a hypersurface in P_{n+1} provided that $n \geq 3$, and which reduces to the consideration of the group of all projectivities leaving $H_{n,d}$ invariant as a whole. From then on one needs a rather elementary but lengthy examination of polynomial algebra.

Samuel, Pierre 5820

Le théorème de Hahn-Banach en géométrie algébrique.

Univ. e Politec. Torino Rend. Sem. Mat. **20** (1960/61), 127–134.

A discussion of a number of results proved elsewhere [e.g., J. Reine Angew. Math. **204** (1960), 1–10; MR **24** #A3165]. The main result concerns a morphism $f: V' \to V$ of normal varieties, the groups $\mathfrak{G}$ of divisors on V whose support does not contain $f(V')$ and $\mathfrak{G}'$ of divisors on V' with real coefficients, and affirms the existence of a homomorphism $\mathfrak{G} \to \mathfrak{G}'$ which is of local character, preserves positivity, and is the correct thing for divisors of functions.

★**Einführung in die Theorie der algebraischen Zahlen und Funktionen.**

Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften, Mathematische Reihe, Band 27.

Birkhäuser Verlag, Basel-Stuttgart, 1963. 338 *pp.* *sFr.* 59.00.

Three books peacefully coexist between the covers of this work: one on algebraic functions of one variable, an introduction to algebraic number theory, and an exposition of modular forms with some applications to analytic number theory. Their association is rather loose, and occasionally a turn of the page means not only a change of scene but a new cast of characters as well. However, the modular forms gain by being placed in the context of algebraic function theory and serve to illustrate it as well, while the elementary substratum common to algebraic numbers and functions is well known.

The book on algebraic functions has the usual material leading up to the Riemann-Roch theorem and the Abel-Jacobi theorem for Riemann surfaces. Most books stop there, but this one goes on to the higher differentials, reduction modulo p, and a long chapter on correspondences ending with the Riemann hypothesis for function fields. The approach is algebraic, studying a function field K of transcendence degree 1 over its constant field k, but it is not invariant: almost always the author proves his result first for a field $k(x)$, and then extends it by studying the layer $K/k(x)$. In other words, the corresponding Riemann surface is thought of as a finite covering of the sphere, rather than as an abstract complex manifold.

The ideal theory is done simultaneously for number and function fields, using both the Dedekind and the Kronecker approaches (the account of the latter is quite elegant). Valuations are not introduced explicitly, nor are the completions. For those with concrete tastes or analytic backgrounds, the same material is redone from scratch (for function fields) via power series and Puiseux expansions; then come the Riemann-Roch theorem and the differentials. After that is the chapter on Riemann surfaces—the basic facts of their construction and topology are assumed, but summarized rapidly—going as far as the Abel-Jacobi theorem, but not discussing uniformization. Finally, we have the chapter on correspondences, done both field-theoretically, as in Deuring's works, and in the classical case by Riemann surface theory. Roquette's proof of the Castelnuovo inequality is given.

The book on number theory is of more modest dimensions: beyond the aforementioned chapter on ideal theory, there is an account of the Hilbert ramification theory, a rapid treatment of class number and the unit theorem, the Minkowski estimates, and quadratic and cyclotomic fields.

The book on modular forms must be hunted for, but it is all there. An appendix to the first chapter gives in twenty pages the elementary facts about the general symplectic group of nth degree, gives the fundamental domain for $n=1$, proves the transformation law for theta functions, and discusses their connection with quadratic forms, including proofs of the reciprocity law and the sign of the Gauss sum. The modular forms appear in the chapter on Riemann surfaces. The account is classical, including Eisenstein series and the forms of level N, the theta functions being special cases. Finally, in the last chapter on correspondences, we get the ring of modular correspondences, its representation on the differentials and its connection with the Ramanujan conjecture—this last being proved at the end of the book for a special case by using the Riemann hypothesis for function fields.

Naturally, in all of this one of the author's problems has been that the pages of a book are linearly ordered, but their mathematical content cannot be. The sequence of topics he has opted for is as good as any, but will be particularly hard on anyone interested in the Riemann-Roch theorem, essential steps of the proof (which is modeled after Dedekind and Weber) being strewn over three chapters. Three or four different definitions of divisor are given and proved equivalent. One of these, the "linear divisor", is apparently a purely ad hoc invention to enable the author to give the linear core of the theorem in Chapter I; here it is shown to be formally somewhat like Minkowski's theorem on linear forms, and the two appear side by side as a sort of prologue to the rest.

The expository style is variable. In places it is leisurely; in others (particularly the number theory and theta functions) rapid. Theorems are not numbered or even labeled as theorems; they are distinguished only by italic script, and sometimes have to share the same sentence with discussion. The notations and running hypotheses are rarely included in the statements, but must usually be extracted from the context (which in at least one case means the preceding chapter). Little local problems (conflicting notation, interpolations in proofs without warning, discontinuities of argument) are also troublesome. In one place a starred—and thus presumably omittable—section is used essentially in the very next paragraph.

The above do not make the book unreadable, but they do add extrinsic difficulties to a hard enough subject. There are good historical notes, as well as brief summaries of the existing state of things. The book is really a text, not a monograph, despite the virtual absence of exercises. For those interested in algebraic functions, it is probably a better source than the comparable book of Chevalley

[*Introduction to the theory of algebraic functions of one variable*, Amer. Math. Soc., New York, 1951; MR 12, 64]; it is more discursive, attempts to illuminate the subject by using a variety of methods, and of course goes much further. The treatment of the other two subjects is more or less classical; it is the best source for the theory of modular correspondences, however. The general shortcomings of the field-theoretic approach for the study of higher-dimensional problems, and even for the deeper aspects of the one-dimensional case, have been noted elsewhere, and more passionately; no other method, however, will take one so far in such a short space. The book is recommended for those studying algebraic functions, as well as for those interested in the other two subjects in a fairly broad context.

A. Mattuck (Cambridge, Mass.)

Gröbner, Wolfgang 5822

Applicazioni delle serie di Lie nella geometria algebrica.

Univ. e Politec. Torino Rend. Sem. Mat. **20** (1960/61), 217–226.

A one-dimensional Lie series is defined as the expansion, in powers of t, of the function $\exp(tD)f(z)$, where

$$D = \vartheta_1(z)\frac{\partial}{\partial z_1} + \cdots + \vartheta_n\frac{\partial}{\partial z_n},$$

and where $\vartheta_1(z), \cdots, \vartheta_n(z), f(z)$ are holomorphic functions of $z_1, \cdots, z_n$ in a certain domain. Similarly, one may define a d-dimensional Lie series by means of the function $\exp(t_1D_1 + \cdots + t_dD_d)$, where $D_1, D_2, \cdots, D_d$ are differential operators analogous to D.

If V_d is an irreducible algebraic variety of a projective space S_n of homogeneous coordinates $(x_0, x_1, \cdots, x_n)$, all the forms containing V_d constitute a prime ideal $(f_1, f_2, \cdots, f_l)$, say. Writing $f_{ik} = \partial f_i/\partial x_k$, we can form $d+1$ operators

$$D_j = \vartheta_{j0}\frac{\partial}{\partial x_0} + \vartheta_{j1}\frac{\partial}{\partial x_1} + \cdots + \vartheta_{jn}\frac{\partial}{\partial x_n} \quad (j = 0, 1, \cdots, d)$$

associated with V_d. The author shows that the parameters $t_1, t_2, \cdots, t_d$ which appear in the corresponding Lie series are simple integrals (not in general of the first species) attached to V_d.

L. Roth (London)

Hoyt, William L. 5823

Embeddings of Picard varieties.

Proc. Amer. Math. Soc. **15** (1964), 26–31.

Let V be a subvariety of a projective space. Assume that V is an irreducible normal variety. Let H be a hypersurface of degree d in the ambient projective space. When we denote by $P(V)$, $P(V\cdot H)$ the Picard varieties of V, $V\cdot H$, respectively (assuming always that $V\cdot H$ is defined, irreducible and normal), there is a natural homomorphism λ of $P(V)$ into $P(V\cdot H)$. The reviewer proved that λ is a purely inseparable injection and that it is surjective when $\dim V > 2$ [Natur. Sci. Rep. Ochanomizu Univ. **4** (1954), 164–171; MR **16**, 163] when H is a generic hypersurface over a defining field of V. In this paper the author proves that λ is an injection (i.e., an everywhere biregular, birational isomorphism of $P(V)$ into $P(V\cdot H)$) for almost all H, provided that the degree of the hypersurface H is sufficiently large.

A correction to "On the moduli of Abelian varieties with multiplications".

J. Math. Soc. Japan **16** (1964), 182.

The author remarks that G. Shimura pointed out that Lemma 1, p. 370, of the author's paper [same J. **15** (1963), 367–386; MR **28** #3995] does not hold when k is an imaginary extension. He indicates the modifications in subsequent results. *R. J. Crittenden* (Providence, R.I.)

Barsotti, Iacopo 5826

Metodi analitici per varietà abeliane in caratteristica positiva. Capitoli I, II.

Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 1–25.

This paper is devoted to an extension of the theory of Witt vectors. The new objects which are introduced arise in connection with points of order p^n on an abelian variety in characteristic p and will be used to study these varieties —the endomorphisms, the local analytic group, etc.

Let R be a ring of characteristic p in which every element has a unique pth root, which contains a perfect subfield k, and which is assumed also to be complete under a reasonable topology. Vect R denotes then the (topological) ring of infinite Witt vectors over R. The new objects bear approximately the same relation to the Witt vectors as Laurent series do to ordinary power series.

First Cov R (the Witt covectors) is introduced as the set of sequences $(\cdots, x_{-2}, x_{-1})$ from R satisfying a suitable convergence condition. Like the Witt vectors, they are added by certain universal formulas for the components, and there are natural operators t, π, and p on them. Cov R is a topological (Vect k)-module. The bivectors $(\cdots, x_{-1}, x_0, x_1, \cdots)$ are then defined as those sequences for which $(\cdots, x_n)$ is a covector for all n. They form a topological group which is completable to Biv R. This last is a complete topological ring, as well as a topological (Vect R)-module. Finally, the topology in R permits the introduction of analysis—the exponential, logarithmic and Artin-Hasse exponential series are introduced and briefly studied.

A. Mattuck (Cambridge, Mass.)

Lubin, Jonathan 5827

One-parameter formal Lie groups over $\mathfrak{p}$-adic integer rings.

Ann. of Math. (2) **80** (1964), 464–484.

Soit $\mathfrak{o}$ un anneau de valuation discrète complet, de caractéristique 0, d'idéal maximal $\mathfrak{p}$ tel que le corps résiduel $k=\mathfrak{o}/\mathfrak{p}$ soit de caractéristique $p>0$. L'auteur étudie les lois de groupe formel à un paramètre F à coefficients dans $\mathfrak{o}$, et spécialement l'anneau des endomorphismes formels $\mathrm{End}_{\mathfrak{o}}(F)$ d'une telle loi de groupe. En associant à un tel endomorphisme (qui est une série formelle à coefficients dans $\mathfrak{o}$) le coefficient de son terme du premier degré, il montre qu'on obtient un isomorphisme de $\mathrm{End}_{\mathfrak{o}}(F)$ sur un sous-anneau fermé de $\mathfrak{o}$. D'autre part, par réduction mod $\mathfrak{p}$, la loi de groupe F donne une loi de groupe formel F^* sur k; si la hauteur h de F^* est finie, on montre que l'homomorphisme $\mathrm{End}_{\mathfrak{o}}(F) \to \mathrm{End}_k(F^*)$ est injectif, ce qui a pour conséquence que $\mathrm{End}_{\mathfrak{o}}(F)$ a un corps des fractions qui est une extension de $\mathbf{Q}_p$ dont le degré est un diviseur de h. On en déduit que lorsqu'on considère des anneaux de valuation discrète complets assez grands $\mathfrak{o}'$ contenant $\mathfrak{o}$, $\mathrm{End}_{\mathfrak{o}'}(F)$ devient indépendant de $\mathfrak{o}'$ (anneau absolu des endomorphismes de F). L'auteur montre ensuite que si les coefficients des termes de degré total $\le p^h$ dans F appartiennent à un sous-anneau de $\mathfrak{o}$ dont le corps des fractions est une extension non ramifiée de $\mathbf{Q}_p$, alors $\mathrm{End}_{\mathfrak{o}}(F)$ est intégralement clos, et son corps des fractions une extension non ramifiée de $\mathbf{Q}_p$. Ceci l'amène à considérer une classe spéciale de lois de groupe F, dites "pleines", pour lesquelles l'anneau absolu d'endomorphismes $\mathrm{End}(F)$ est intégralement clos et de rang h (égal à la hauteur de F^*) sur $\mathbf{Z}_p$; l'auteur montre que si en outre $\mathfrak{o}/\mathfrak{p}$ est algébriquement clos, ces lois de groupe sont déterminées à isomorphisme près par $\mathrm{End}(F)$. En outre il construit des lois de groupe "pleines" pour lesquelles l'anneau $\mathrm{End}(F)$ est isomorphe à l'anneau des entiers dans une extension finie quelconque de $\mathbf{Q}_p$. Il montre d'autre part qu'il y a des lois de groupe non "pleines".

Badaljan, A. E. 5829

On a variational problem. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk **17** (1964), no. 3, 3–6.

In dealing with large velocities one meets the following problem: Given the quadratic matrix $A=[a_{ij}]$, $i,j=1,2,\cdots,n$, and let Φ be the set of all admissible mutual uniform self-mappings of the set $\{1,2,\cdots,n\}$, determine

$$\min_{\varphi\in\Phi} \max_i \{a_{i\varphi(i)}\}, \qquad i=1,2,\cdots,n,$$

and the mapping φ for which the above-mentioned extremum is attained. One theorem regarding necessary and sufficient conditions for this extremum is investigated. The proof is very complicated, hence the author does not give the general formula. At the end of the paper it is shown that the same special problem can also be treated and solved. *D. P. Rašković* (Belgrade)

Hakuhara, Masuo 5830

Sur la dépendance linéaire de trois applications linéaires.

Funkcial. Ekvac. **6** (1964), 47–54.

Let H_1, H_2, H_3 be linear transformations from a vector space V to a vector space V' such that $H_i(X) \subset H_j(X) + H_k(X)$ for any subspace X of V and any permutation (i, j, k) of $(1, 2, 3)$. The author asserts that under these conditions H_3 is a linear combination of H_1 and H_2, and he generalizes this to $n+1$ linear transformations, with an additional condition. The proofs are based on a lemma for which an incorrect demonstration is given. Thus the asserted results remain doubtful.

The author does not even mention the field of scalars underlying V and V', but he assumes tacitly that this field is algebraically closed. Without this assumption, his results are false. *O. Wyler* (Albuquerque, N.M.)

Stoer, Josef 5831

On the characterization of least upper bound norms in matrix space.

Numer. Math. **6** (1964), 302–314.

For any norm on n-space, the set $\{x : \|x\| \leq 1\}$ is compact, convex and contains 0; conversely, such a set defines a vector norm. It is harder to describe all (sub-multiplicative) matrix norms, although those induced by vector norms, $\|A\| = \sup \|Ax\|/\|x\|$, form a simple subclass. The author proves that they are exactly the minimal matrix norms. He also defines the dual matrix norm of A by $\sup \mathrm{Re}(\mathrm{trace}\, AB/\|B\|)$, and investigates some of its properties. *W. G. Strang* (Cambridge, Mass.)

Černikov, S. N. 5832

Fundamental theorems in the theory of linear inequalities. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 1181–1190.

The author points out and proves several logical relations among some well-known basic theorems on finite systems of linear inequalities. *Ky Fan* (Evanston, Ill.)

Ehlich, Hartmut 5833

Determinantenabschätzung für binäre Matrizen mit $n \equiv 3 \bmod 4$.

Math. Z. **84** (1964), 438–447.

Let $A = [a_{ij}]$ be a matrix of order n with entries $a_{ij} = \pm 1$ and let α_n denote the maximum of the absolute values of the determinants of all such $(+1, -1)$-matrices of order n. It has been previously shown that

$$\begin{aligned} \alpha_n^2 &\leq n^n = h_n^2 && \text{for } n \equiv 0 \pmod 4, \\ &\leq (n-1)^{n-1}(2n-1) && \text{for } n \equiv 1 \pmod 2, \\ &\leq 4(n-2)^{n-2}(n-1)^2 && \text{for } n \equiv 2 \pmod 4, \end{aligned}$$

and the present paper concentrates on the case $n \equiv 3 \pmod 4$. Define the sets of matrices of order m $(1 \leq m \leq n)$

$$\mathfrak{a}_m = \{C_m \mid C_m = [c_{ij}],\ c_{ii} = n,\ c_{ij} \equiv 3 \pmod 4,\ i, j = 1, \cdots, m\},$$

and let C_m^* denote those matrices in $\mathfrak{a}_m$ with $\det C_m^*$ maximal. One knows that $\alpha_n^2 \leq \det C_n^*$ for $n \equiv 3 \pmod 4$, and the main portion of the present paper deals with the evaluation of $\det C_n^*$. This evaluation takes the form $\det C_n^* = \max\{D_n(s) \mid 1 \leq s \leq n\}$, where the function $D_n(s)$ is evaluated explicitly. One may deduce, for example, that

$$\alpha_n^2 \leq \frac{4 \cdot 11^6}{7^7} (n-3)^{n-7} n^7, \qquad n \equiv 3 \pmod 4,\ n \geq 63.$$

Wojtas, M. 5834

On Hadamard's inequality for the determinants of order non-divisible by 4.

Colloq. Math. **12** (1964), 73–83.

If A_n is a real $n \times n$ matrix with $-1 \leq a_{ij} \leq 1$, then $|A_n|^2 \leq n^n$, with equality possible only for $n = 1, 2$, or $4t$ $(t = 1, 2, 3, \cdots)$. For odd n this bound was improved to $|A_n|^2 \leq (2n-1)(n-1)^{n-1}$ by G. Barba [Giorn. Mat. Battaglini (3) 71 (1933), 70–86]. The present author considers the case $n \equiv 2 \pmod 4$ and shows that $|A_n|^2 \leq 4(n-1)^2(n-2)^{n-2}$. This result has also appeared recently (apparently independently) in H. Ehlich [Math. Z. **83** (1964), 123–132; MR **28** #4003]. The interested reader should also see H. Ehlich [#5833 above].

On the characteristic roots of non-negative matrices.

Recent Advances in Matrix Theory (Proc. Advanced Seminar, Math. Res. Center, U.S. Army, Univ. Wisconsin, Madison, Wis., 1963), pp. 3–38. Univ. Wisconsin Press, Madison, Wis., 1964.

This is a general discourse on the subject of characteristic roots of real matrices with non-negative elements, principally concerned with the author's contributions over the past few years. The topics discussed include the following: theorems concerning the location of characteristic roots in ovals of Cassini; characteristic roots of stochastic matrices; the Perron-Frobenius theorems on positive matrices; characteristic roots of power-positive matrices; the theorems of Frobenius on non-negative matrices; stochastic matrices with real characteristic roots α, β such that $|\alpha| > |\beta| \geq |\gamma|$ for any other root γ.

The results given have for the most part been published previously, but some new work is included. Nearly all proofs of theorems are given.

Dionísio, J. J. [Dionísio, José Joaquim] 5837

An extension of a result of Schur. (Portuguese. English summary)

Univ. Lisboa Revista Fac. Ci. A (2) **9** (1961/62), 307–310.

The theorem stated in this paper says that if E^n is a unitary space and $\lambda \neq 0$ is a characteristic root of a linear transformation represented by the matrix A, then, in order that no non-zero vector in N_λ, the null space of $A-\lambda I$, is orthogonal to a non-zero vector in the null space of the adjoint transformation $A^*-\bar{\lambda}I$, the dimension of N_λ has to be equal to the multiplicity of the root λ in the characteristic polynomial of A. The author proves the theorem by showing that λ must be a simple root of the minimal polynomial, but he overlooks the fact that his condition also implies that dim $N_\lambda = 1$.

Dionísio, José Joaquim 5838

Non-negative matrices. (Portuguese)

Univ. Lisboa Revista Fac. Ci. A (2) **10** (1963), 5–35.

This is an expository paper describing the spectral properties of non-negative matrices, i.e., square matrices whose entries are non-negative real numbers. Proofs are included. Some of the results are proved for Perron matrices, defined by the author as square real matrices for which there exists a real polynomial $f(x)$ such that the coefficients of the matrix $f(A)$ are all positive.

Pruitt, William E. 5839

Eigenvalues of non-negative matrices.

Ann. Math. Statist. **35** (1964), 1797–1800.

Let $P=(p_{ij})$, $i,j=0,1,2,\cdots$, be a non-negative infinite matrix which is irreducible in the sense that the transitive closure of the relation $\{(i,j); p_{ij}>0\}$ contains all pairs (i,j), and let λ be a positive number. The author gives a necessary and sufficient condition (too complicated to reproduce here) for the existence of a non-negative, non-zero vector x satisfying $Px=\lambda x$. The method adopted is to use some results of Vere-Jones [Quart. J. Math. Oxford Ser. (2) **13** (1962), 7–28; MR **25** #4571] to reduce the problem to the case in which $\sum_i p_{ij} \leq 1$ for all j, and then to apply a theorem of Harris [Proc. Amer. Math. Soc. **8** (1957), 937–942; MR **19**, 989] and Veech [Proc. Amer. Math. Soc. **14** (1963), 856–860; MR **27** #6302] to the transpose of P. A by-product of the argument is a description of the set of non-negative solutions x of the inequality $Px \leq \lambda x$.

Bogdanov, Ju. S. 5840

Transforming a variable matrix to canonical form. (Russian)

Dokl. Akad. Nauk BSSR **7** (1963), 152–154.

The work reported on was presented in a seminar at Leningrad University in 1947; applications of the work have appeared, making it desirable to present proofs. Theorem 1 is as follows. Let $\Delta=(a,b)$. Let A be a matrix of elements, each of which is a continuous function of t, $t\in\Delta$. If $\tau\in\Delta$ is such that in some neighborhood of τ, multiplicities (and degrees of the elementary divisors) of the proper values of A do not change, τ is called a c-point; the set of c-points Δ_A is clearly everywhere dense. There is a matrix V, continuous on Δ_A, that transforms A into Jordan form. Nothing more is true; all such matrices V may be discontinuous at every point of $\Delta\setminus\Delta_A$. Theorem 2 states a corresponding result for a matrix A of elements, each of which is holomorphic in a region of the z-plane.

Pless, Vera 5841

On Witt's theorem for nonalternating symmetric bilinear forms over a field of characteristic 2.

Proc. Amer. Math. Soc. **15** (1964), 979–983.

Let k be a field of characteristic 2, let f be a bilinear form on a finite-dimensional vector space V over k, which is non-alternating ($f(x,x)\neq 0$ for some $x\in V$) and non-degenerate. Moreover, it is assumed that the values $f(x,x)$ lie in a subfield of k which is contained in k^2. Under these assumptions there exists a unique h in V such that $f(h,x)^2=f(x,x)$ for all x in V. The author proves a theorem of Witt type for this situation. The theorem can be stated as follows. Let σ be a linear transformation defined on a subspace U of V such that $f(\sigma(x),\sigma(y))=f(x,y)$ for x, y in V. Then σ can be extended to a linear transformation defined on all of V with the same property if and only if the following holds: (i) if $h\in U$, then $\sigma(h)=h$; (ii) if $h\notin U$, then $h\notin\sigma(U)$. From this, one gets as corollaries results on maximal isotropic subspaces of V and conditions for two subspaces of V to be transformable into each other by a transformation in the orthogonal group of f.

T. A. Springer (Utrecht)

Virier, Marcel 5842

Sur certaines équivalences de matrices.

C. R. Acad. Sci. Paris **259** (1964), 497–500.

Let $M\in(p\times p)_K$ be a $p\times p$ matrix over a commutative field K. If $x^k\Phi(x)$ is the minimal polynomial of M, where $\Phi(0)\neq 0$, the rank of M^k is called the height of M. The note is concerned with $mp\times mp$ matrices T that are partitioned into $p\times p$ matrices M_{ij} $(i,j=1,2,\cdots,m)$ which commute in pairs. The set of matrices $\{M_{ij}\}$ generates a commutative K-ring H. The nil ideal of H is denoted by N. An equivalence transformation on T is a sequence of elementary transformations acting on the rows or columns of T, where T is regarded as a matrix over H. The following theorem is proved: T is equivalent to a diagonal matrix over H/N in which the heights of the diagonal terms do not increase.

Fulkerson, D. R. 5843

The maximum number of disjoint permutations contained in a matrix of zeros and ones.

Canad. J. Math. **16** (1964), 729–735.

Let A be an arbitrary m-by-n (0, 1)-matrix with $m\leq n$. Let

$$(1)\qquad A=P_1+P_2+\cdots+P_p+R,$$

where R is a (0, 1)-matrix and each P_i $(i=1,\cdots,p)$ is a permutation matrix. Let $\pi=\pi(A)$ denote the maximum value of the integer p among decompositions of A of the

form (1). The main theorem in this paper gives an explicit formula for $\pi(A)$, namely,

(2) $$\pi(A) = \min_{A'}\left[\frac{N_1(A')}{s(A')}\right],$$

where A' is an e-by-f minor of A, $N_1(A')$ denotes the number of 1's in A', $s(A') = e+f-n$, brackets denote the largest integer, and the minimum is over all minors A' of A with $s(A') > 0$. The proof is constructive and singles out a critical minor A' of A that yields the minimum in (2). In case A is n-by-n with precisely p 1's in each row and column, then the formula reduces to the familiar $\pi(A) = p$.

Using the formula and a result due to Haber, one may evaluate

(3) $$\tilde{\pi} = \min_{A \in \mathfrak{A}} \pi(A),$$

where $\mathfrak{A}$ is the class of all m-by-n (0, 1)-matrices that have the same row and column sums as A. The determination of the minimum value of p in the decomposition (1) for a fixed A under the assumption that R contains no permutation and the determination of the maximum value of $\pi(A)$ over the class $\mathfrak{A}$ generated by A remain open.

Die Charakterisierung der Determinanten über einem unendlichen Integritätsbereich mittels Funktionalgleichungen.

Publ. Math. Debrecen **10** (1963), 244–253.

In a previous paper [same Publ. **3** (1954), 257–260; MR **17**, 338] the author gave an axiomatic characterization of the determinant function on matrices over an integral domain (commutative and with 1) of characteristic 0. In the present paper this characterization is extended to matrices over any infinite integral domain R. Let R_n be the ring of n-square matrices with entries in R and let φ be a function on R_n into R, not identically zero, satisfying the following axioms: (a) $\varphi(A+B) = \sum \varphi(C)$, where the summation extends over all 2^n matrices C whose jth column is either the jth column of A or the jth column of B, $j = 1, \cdots, n$; (b) $\varphi(AB) = \varphi(A)\varphi(B)$; (c) $\varphi(aA) = a^n\varphi(A)$, for all A, B in R_n and all a in R. Then $\varphi(A)$ is the determinant of A.

The paper concludes with counter-examples showing that the axioms (a), (b) and (c) are independent and that the condition that R be infinite cannot be dropped.

H. Minc (Santa Barbara, Calif.)

Marcus, Marvin 5845

The Hadamard theorem for permanents.

Proc. Amer. Math. Soc. **15** (1964), 967–973.

Let per A denote the permanent of the $n \times n$ matrix $A = (a_{ij})$. The author and M. Newman [Ann. of Math. (2) **75** (1962), 47–62; MR **25** #96] conjectured that the inequality

(*) $$\operatorname{per} A \geq a_{11}a_{22}\cdots a_{nn}$$

is valid for every non-negative hermitian matrix A, and a result somewhat weaker than (*) was subsequently established by the author and H. Minc [Trans. Amer. Math. Soc. **104** (1962), 510–515; MR **25** #3059]. In the present paper it is shown that if A is a non-negative hermitian $n \times n$ matrix and $1 \leq i \leq n$, then

(**) $$na_{ii} \operatorname{per} A_i \geq \operatorname{per} A \geq a_{ii} \operatorname{per} A_i,$$

where A_i denotes the matrix obtained when the ith row and the ith column are deleted in A. From (**), the inequality (*) follows by a simple process of induction. The cases of equality in both (*) and (**) are discussed fully.

L. Mirsky (Sheffield)

Slater, Morton L.; Thompson, Robert J. 5846

A permanent inequality for positive functions on the unit square.

Pacific J. Math. **14** (1964), 1069–1078.

The van der Waerden conjecture states that the permanent $P = \sum_{\sigma \in \mathfrak{S}} \prod_{i=1}^n a_{i\sigma(i)}$ of a doubly stochastic matrix (a_{ij}), where $\mathfrak{S}$ is the group of all permutations of $1, \cdots, n$, satisfies $P \geq n!n^{-n}$. It follows from this conjecture that $\prod_{i=1}^n a_{i\sigma(i)} \geq n^{-n}$ for some $\sigma \in \mathfrak{S}$. Marcus and Minc [Proc. Amer. Math. Soc. **13** (1962), 571–579; MR **25** #3057] proved the following related result. If $\prod a_{ii}$ is not exceeded by any other term of the permanent, then

(1) $$\sum \log a_{ii} \geq \sum\sum a_{ij} \log a_{ij} \geq -n \log n.$$

The authors give a very nice proof of (1), and they generalize (1) to functions on $I \times I$, where $I = [0, 1)$ is the half-open unit interval, as follows. Let f be a measurable function on $I \times I$ satisfying: (1°) $f(x, y) > 0$, and

$$\int_0^1 f(x, y)\,dx = 1 = \int_0^1 f(x, y)\,dy$$

for all $x, y \in I$; (2°) for all measure-preserving bijective transformations T on I, $f(x, Tx)$ is measurable, and

$$-\infty < \int_0^1 \log \frac{f(x, Tx)}{f(x, x)}\,dx \leq 0;$$

(3°) $$\int_0^1 \left|\log \frac{f(x, x+\delta)}{f(x, x)}\right| dx \to 0 \text{ as } \delta \to 0$$

(put $f(x, y+1) = f(x, y)$).

Then $f \log f$ is integrable on $I \times I$, and

$$\infty > \int_0^1 \log f(x, x)\,dx \geq \int_0^1 \int_0^1 f(x, y) \log f(x, y)\,dx\,dy \geq 0.$$

Serie convergenti su un corpo non archimedeo con applicazione ai fasci analitici.

Ann. Mat. Pura Appl. (4) **65** (1964), 113–125.

Soient K un corps valué complet pour une valeur absolue valuative, et A l'anneau de la valuation correspondante. Une série formelle restreinte est un élément $\sum_i c_i X^i \in K[[X_1, \cdots, X_n]]$ tel que c_i tende vers 0 quand $|i|$ tend vers l'infini (i désignant un multi-indice); la condition que c_i tende vers 0 signifie que, pour tout point x du

polydisque unité U de K^n, la série $f(x) = \sum_i c_i x^i$ est absolument convergente; les fonctions f ainsi obtenues s'appellent les fonctions strictement holomorphes sur U. Les séries formelles restreintes forment un sous-anneau $K\{X_1, \cdots, X_n\}$ de $K[[X_1, \cdots, X_n]]$, dans lequel le théorème de préparation de Weierstrass est vrai, et qui est noethérien et factoriel. Soient $\mathfrak{O}$ le faisceau des germes de fonctions holomorphes sur le polydisque U, et $s_1, \cdots, s_p$ des sections strictement holomorphes de $\mathfrak{O}$; alors le faisceau des relations entre les s_i est de type fini, et est engendré par un nombre fini de relations à coefficients strictement holomorphes. *P. Samuel* (Paris)

Fried, Erwin [Fried, Ervin] 5848
Beiträge zur Theorie der Frobenius-Algebren.
Math. Ann. **155** (1964), 265–269.

Let A be a Frobenius algebra with radical N and let I be the annihilator of N. An idempotent e is called principal if the residue class of e in A/N is in the center. A is called reduced if no principal idempotent except 0 and 1 has the property $eI = Ie$. A reduced algebra is indecomposable (in fact, indecomposability is equivalent to $eI_2 \neq I_2 e$, where I_2 is the annihilator of N^2). Let e be principal; then $eI = Ie$ if and only if eAe is Frobenius and the annihilator of its radical is eIe. If e is a minimal principal idempotent, then eAe is reduced.

If A is reduced, then I is a power of N, A/N is a direct sum of isomorphic simple algebras, and the minimal, orthogonal, primitive idempotents $e_1, \cdots, e_n$ can be chosen so that $e_i I = I e_{i+1}$. *D. Zelinsky* (Evanston, Ill.)

Jacobson, N. 5849
Clifford algebras for algebras with involution of type D.
J. Algebra **1** (1964), 288–300.

Let k be a field of characteristic $\neq 2$. An algebra with involution over k is a pair $(\mathfrak{A}, J)$, where $\mathfrak{A}$ is a finite-dimensional associative algebra over k and J an involution in $\mathfrak{A}$. This paper deals mainly with algebras with involution which are simple of type D_l. These are defined as follows: There is an algebraic extension K of k and an isomorphism of the K-algebra $\mathfrak{A} \otimes_k K$ onto the algebra of matrices over K with $2l$ rows and columns, which transforms $J \otimes 1$ into the adjoint mapping relative to a nondegenerate symmetric matrix, which has maximal Witt index. One may assume K to be a finite Galois extension of k.

In this paper a construction is given of the even Clifford algebra $\mathfrak{C}^+(\mathfrak{A}, J)$ of any algebra with involution of type D_l. This generalizes the even Clifford algebra of a quadratic form of even rank. The construction is by a Galois descent argument, which is more or less standard. The author then gives some results concerning the structure of $\mathfrak{C}^+(\mathfrak{A}, J)$. It is an algebra with involution ι over k. In the case where $\mathfrak{A}$ is the algebra of matrices with $2l$ rows and columns over k and J the adjoint mapping relative to a nondegenerate symmetric matrix S, $\mathfrak{C}^+(A, J)$ is isomorphic to the even Clifford algebra of the quadratic form associated with S, and ι is the main involution in that algebra. $\mathfrak{C}^+(A, J)$ is either the direct sum of two simple ideals $\mathfrak{C}_1$ and $\mathfrak{C}_2$ (case D_{II}) or is simple (case D_{III}). The most interesting case is D_{II}, l even. Then ι maps the simple ideals $\mathfrak{C}_1$ and $\mathfrak{C}_2$ into themselves. It is proved that in this case the sum of the elements of the Brauer group of k, defined by $\mathfrak{A}$, $\mathfrak{C}_1$ and $\mathfrak{C}_2$, is zero. The proof of this fact involves an interesting generalization of the classical principle of triality. *T. A. Springer* (Utrecht)

Mauldon, J. G. 5850
Nonorthogonal idempotents whose sum is idempotent.
Amer. Math. Monthly **71** (1964), 963–973.

The main result of the paper is contained in Theorem 1: For every integer $n > 2$ there exists a ring $\mathfrak{R}$ (with unit) whose additive group is torsion-free, containing a set $\{a_1, a_2, \cdots, a_n\}$ of n idempotents whose sum is idempotent, such that $a_i a_j \neq 0$ for all $i, j = 1, 2, \cdots, n$. The author first constructs a ring $\mathfrak{R}_1$ containing four mutually non-orthogonal idempotents whose sum is the unit e. The tensor product $\mathfrak{R}_k$ of a suitable number of copies of $\mathfrak{R}_1$ (regarded as an algebra over the integers) satisfies the conditions of the theorem if $n \not\equiv 2 \pmod 3$. The author also constructs a ring $\mathfrak{R}_0$ containing four mutually non-orthogonal idempotents whose sum is zero. The proof of the theorem is then completed by considering rings of the form $\mathfrak{R}_0 \otimes \mathfrak{R}_k$. *R. A. Melter* (Amherst, Mass.)

Onodera, Takesi 5851
On semi-linear normal basis.
J. Fac. Sci. Hokkaido Univ. Ser. I **18** (1964), 23–33.

In this paper a result of Nakayama concerning semi-linear normal basis for fields, and for division rings under certain assumptions [Amer. J. Math. **71** (1949), 241–248; MR **10**, 425], is extended to what has been called strictly Galois extensions of division rings. In particular, the following theorem is proved: Let Δ be a division ring and let Φ be a division subring of Δ. Suppose that $[\Delta:\Phi]_r = n$, that $\mathfrak{G}_0$ is a group of automorphisms of Δ whose fixed subring is Φ, and that the order of $\mathfrak{G}_0$ is n. Let Λ be a division subring of Δ which is invariant under $\mathfrak{G}_0$. If $[\Delta:\Lambda]_r = nq + r$ $(0 \leq r < n)$, then there exist $q+1$ elements $\xi_1, \xi_2, \cdots, \xi_q, \rho$ in Δ such that $\{\xi_i^\sigma \mid \sigma \in \mathfrak{G}_0, i = 1, 2, \cdots, q\}$, together with suitable r-elements in $\{\rho^\sigma \mid \sigma \in \mathfrak{G}_0\}$, is a right basis for Δ over Λ. If $[\Delta:\Lambda]_r$ is infinite, then there exist elements ξ_α, $\alpha \in A$, in Δ such that $\{\xi_\alpha^\sigma \mid \sigma \in \mathfrak{G}_0, \alpha \in A\}$ is a right basis for Δ over Λ, where A is a set of cardinality $[\Delta:\Lambda]_r$.

A result of Kasch on normal bases for Galois extensions of division rings [Math. Ann. **126** (1953), 447–463; MR **15**, 597] is generalized to semi-linear normal basis [see also #5852 below]. *J. K. Goldhaber* (College Park, Md.)

Kishimoto, Kazuo; Onodera, Takesi; Tominaga, Hisao 5852
On the normal basis theorems and the extension dimension.
J. Fac. Sci. Hokkaido Univ. Ser. I **18** (1964), 81–88.

Let Δ be a division ring, Φ a division subring of Δ, and $\mathfrak{G}$ the group of automorphisms of Δ which fix Φ. Kasch [Math. Ann. **126** (1953), 447–463; MR **15**, 597] has proved that Δ is $\mathfrak{G}\Delta_r$-isomorphic to $\mathfrak{G}\Delta$, if and only if the centralizer of Φ in Δ is the center of Δ or is contained in Φ. In the paper this result is extended in several ways to simple rings. The following is an example of the type of theorem which the authors prove. Let A be an Artinian ring which is Galois and finite over B, let $\mathfrak{G}$ be the group of automorphisms of A over B, and let N be a $\mathfrak{G}$-invariant simple subring of A. Suppose that the centralizer of B in A is different from the two-by-two matrix ring over GF(2). Then

$[\mathfrak{G}N_r : N_r]_r = [A : B]$ if and only if the centralizer of B in A is the center of A or is contained in N.

The paper also includes an improvement of a theorem of Takazawa and Tominaga [J. Fac. Sci. Hokkaido Univ. Ser. I 15 (1961), 198–201; MR 25 #2099]. In particular, the following theorem is proved. Let A be a simple ring with center C, $\mathfrak{H}$ an F-group of A of order p^e (p a prime), and B the subring of A which is fixed by $\mathfrak{H}$. Let Z denote the center of B. If Z does not contain a primitive pth root of unity, then the centralizer of B in A is $C[Z]$ and $[A : B]$ is a divisor of p^e (and a multiple of $p^f = [\mathfrak{H} : \mathfrak{H}_0]$ times the exponent of $\mathfrak{H}_0$, where $\mathfrak{H}_0$ is the subgroup of $\mathfrak{H}$ consisting of all the inner automorphisms contained in $\mathfrak{H}$). Furthermore, if A is not of characteristic p, then $[A : B] = p^e$.

Sufficient conditions for the existence of a quotient ring. (Russian)

Sibirsk. Mat. Ž. 5 (1964), 1191–1194.

Let R be an associative (not necessarily commutative) ring and S a subset of R which is closed under multiplication but which does not contain zero. The definition of generalized right quotient ring $R(S)$ for R with respect to S was given by V. P. Elizarov [Izv. Akad. Nauk SSSR Ser. Mat. 24 (1960), 153–170; MR 22 #9513]. In the present paper there are given various conditions, each of which is sufficient for the existence of $R(S)$. For example, the existence is guaranteed when the minimal condition is satisfied for right ideals in R. Further, we have the theorem that if R is a ring without zero-divisors and if every direct sum of principal right ideals admits only a finite number of summands, then R can be imbedded in a right quotient division ring. This is a generalization of A. W. Goldie's theorem [Proc. London Math. Soc. (3) 8 (1958), 589–608; MR 21 #1988].

Nobusawa, Nobuo 5855

On a generalization of the ring theory.

Osaka J. Math. 1 (1964), 81–89.

Let A, B be left R-modules for a ring R. Let M be a subgroup of $\mathrm{Hom}_R(A, B)$ and N a subgroup of $\mathrm{Hom}_R(B, A)$. If f, f^1 are in M and g, g^1 in N, then the products fgf^1 and gfg^1 are defined and may lie in M and N, respectively. The author abstracts this situation by considering two abelian groups M, N and postulating the existence of products mnm^1 as an element of M, and nmn^1 as an element of N. These products are subject to several axioms, based on the above concrete situation. The author defines simple and semi-simple with minimum condition in this situation, and proves analogues of the Wedderburn theorems. Thus, a simple pair M, N is shown to consist of the $m \times n$ and $n \times m$ matrices over a division ring with the product the matrix product, and a semi-simple pair is a direct sum of such pairs.

A. Rosenberg (Ithaca, N.Y.)

Samuel, Pierre 5856

Un exemple d'anneau factoriel.

Bol. Soc. Mat. São Paulo 15 (1960), 1–4 (1964).

The object of this paper is to prove the following result. Let K be a noetherian unique factorization domain, and let $x_1, \cdots, x_n$ be indeterminates over K with weights $q(1), \cdots, q(n) > 0$, respectively. Let $F(x)$ be an irreducible element of $K[x]$ which is an isobar of weight q. We put $A = [x, z]$, where $z^c = f(x)$ and c is prime to q. Then A is a unique factorization domain if one of the following conditions holds: (1) $c \equiv 1 \pmod q$; (2) Every projective K-module of finite type is free.

Y. Nakai (Hiroshima)

Ohm, Jack; Schneider, Hans 5857

Matrices similar on a Zariski-open set.

Math. Z. 85 (1964), 373–381.

Let D be an integral domain; for every $\mathfrak{p} \in \mathrm{Spec}(D)$, denote by $D(\mathfrak{p})$ the quotient field of $D/\mathfrak{p}$. Let A be an n-by-n matrix over D; denote by $A(\mathfrak{p})$ the matrix over $D(\mathfrak{p})$ obtained from A by reduction mod $\mathfrak{p}$, and by $\rho_i(\mathfrak{p})$ $(i = 1, \cdots, n)$ the degrees of the invariant factors of $A(\mathfrak{p})$ (in descending order). If B' is a matrix similar to $A(\mathfrak{p})$, then the solution space of $A(\mathfrak{p})X - XB' = 0$ has dimension

$$\tau(\mathfrak{p}) = \sum (2i - 1)\rho_i(\mathfrak{p}).$$

For $\mathfrak{p} \in \mathrm{Spec}(D)$ the following are equivalent: (1) $\rho_i(\mathfrak{p}) = \rho_i(0)$ for every i; (2) there exists a dense set V_i containing $\mathfrak{p}$ such that ρ_i is constant on V_i; (3) there exists a dense set V containing $\mathfrak{p}$ on which τ is constant; (4) τ is minimal at $\mathfrak{p}$. Furthermore, the set U of all $\mathfrak{p} \in \mathrm{Spec}(D)$ for which the preceding properties hold is open. Now let B be another n-by-n matrix over D, and let V be a dense subset of $\mathrm{Spec}(D)$ on which τ (for A) is constant; if $A(\mathfrak{p})$ is similar to $B(\mathfrak{p})$ for every $\mathfrak{p}$ in V, and if $\mathfrak{q} \in V$, then there exists a neighbourhood U of $\mathfrak{q}$ such that A is similar to B on U (i.e., in the corresponding ring of quotients of D).

Now let X be a topological space, K a field, and H a ring of functions $f: X \to K$ such that, for every $f \neq 0$ in H, the zero-set of f is discrete. If no point of X is open, this implies that A is a domain. We associate to every x in X the ideal $\mathfrak{p}_x$ of all f in H such that $f(x) = 0$, thus getting a continuous mapping j of X into $\mathrm{Spec}(H)$; for every non-discrete subset V of X, $j(V)$ is dense in $\mathrm{Spec}(H)$. Then the above result about similarity of matrices remains true with D replaced by H and $\mathrm{Spec}(D)$ by X. This gives a result of Wasow [J. Math. Anal. Appl. 4 (1962), 202–206] about holomorphic matrices.

Sands, A. D. 5858

Primitive rings of infinite matrices.

Proc. Edinburgh Math. Soc. (2) 14 (1964/65), 47–53.

Let R be a ring. Let $M(R)$ denote either the ring of row-finite matrices over R or the ring of infinite matrices over

R in which each matrix has only a finite number of nonzero entries. It is shown that R is primitive if and only if $M(R)$ is, and that an ideal P of R is primitive if and only if $M(P)$ is a primitive ideal of $M(R)$. An example of a primitive ideal in $M(R)$, for a certain R, which is not of the form $M(P)$, is given. The question of the Jacobson radical of $M(R)$ is also touched upon.

Besserre, Annie 5859

Quelques propriétés d'un couple de modules.

C. R. Acad. Sci. Paris **259** (1964), 22–23.

If A is a commutative ring, $E' \subset E$ are modules and $\mathfrak{a}$ is an ideal, then $\mathfrak{a}E \cap E' = \mathfrak{a}E'$ if and only if $\mathfrak{a}_\mathfrak{m} \cap E_\mathfrak{m} = E_\mathfrak{m}'$ for all maximal ideals $\mathfrak{m}$. It follows that whenever E, E' are finitely generated projective modules, the set P of prime ideals such that $\mathfrak{p}E \cap E' = \mathfrak{p}E'$ is open in the Zariski topology of the spectrum. If the hypothesis on E and E' is dropped, P need not be open.

Eine kennzeichnende Eigenschaft der injektiven Moduln.

Wiss. Z. Martin-Luther-Univ. Halle-Wittenberg Math.-Natur. Reihe **11** (1962), 737–739.

Let G be an R-module, $\{g_\beta\}$ a subset of G, $\{f_\beta\}$ a set of linear forms in indeterminates $\{x_\alpha\}$. The author considers three conditions on the system of linear equations $\{f_\beta = g_\beta\}$: "compatible" means $\sum s_\beta f_\beta = 0$ (finite sum, $s_\beta \in R$) implies $\sum s_\beta g_\beta = 0$; "solvable" means there are substitutions $x_\alpha \to h_\alpha$ ($h_\alpha \in G$) sending every f_β to g_β; "translatable (übertragbar)" means there are substitutions for a nonempty set of x_α's such that the resulting system of equations is compatible. Theorem: Solvable implies translatable implies compatible; G is injective if and only if compatible implies translatable, and then all three concepts coincide. A short proof can be given as follows: Let F be the free module on $\{x_\alpha\}$ and H the submodule generated by $\{f_\beta\}$. "Compatible" means there is a homomorphism from H to G carrying every f_β to g_β; "solvable" means there is a homomorphism from F to G carrying f_β to g_β; "translatable" means $F = F_1 \oplus F_2$, with F_1 free and nonzero, and there is a homomorphism from $F_1 + H$ to G carrying f_β to g_β. It is then clear that the conditions are ordered as above and that if G is injective, they all coincide. That compatible implies translatable only if G is injective follows by taking $F = R$ (or rather, R with a unit adjoined if, with the author, we do not postulate a unit in R).

D. Zelinsky (Evanston, Ill.)

Fuchs, L. 5861

Ranks of modules.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 71–78.

A subset $\{a_i\}$ of a left R-module M is called independent if $\sum \lambda_i a_i = 0$ ($\lambda_i \in R$) implies $\lambda_i a_i = 0$. A module has rank 1 if every set of two or more elements is dependent. Consider maximal independent subsets U of M whose elements (1) have prime order [equivalently, generate cyclic modules all of whose nonzero elements have the same order] and (2) generate cyclic modules of rank 1. Under suitable hypotheses on R, such sets U exist in every module, and for every prime ideal P, the cardinal number of elements of order P in such a set U is an invariant of the module, independent of U, called the P-rank of M. The hypotheses on R are that every module contains a module of rank 1, and every module of rank 1 contains an element of prime order [equivalently, R/P is an Ore domain for every prime P, and, for every left ideal L, there is a λ in R such that $L:\lambda$ is prime]. These hypotheses are satisfied by commutative Noetherian rings.

D. Zelinsky (Evanston, Ill.)

Kertész, A. 5862

On ranks of modules. A remark to the preceding paper of L. Fuchs.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 79–82.

The author proves that the definition of P-rank in the preceding paper [#5861] works in modules over arbitrary rings (a module is said to have rank 0 if it has no elements satisfying (1) and (2) in #5861 above). The rings satisfying the hypotheses of the paper above then appear as the rings for which only the zero module has rank 0. If H is a submodule of G, then the 0-rank of H plus the 0-rank of G/H is the 0-rank of G.

D. Zelinsky (Evanston, Ill.)

Northcott, D. G. 5863

The Hilbert function of the tensor product of two multigraded modules.

Mathematika **10** (1963), 43–57.

For K a field, consider the polynomial ring R:

$$K[X_{11}, \cdots, X_{1m_1}, X_{21}, \cdots, X_{2m_2}, \cdots, X_{p1}, \cdots, X_{pm_p}]$$

in p sets of variables. Let D be the direct sum of p copies of the non-negative integers. For $\alpha = (\alpha_1, \alpha_2, \cdots, \alpha_p) \in D$ let $R^{(\alpha)}$ be the set of those polynomials which are homogeneous of degree α_1 in the first set of variables, homogeneous of degree α_2 in the second set of variables, and so on. In this way R is a D-graded ring. Let E and L be finitely generated D-graded R-modules. Then the expressions of the Hilbert functions $H(\alpha, E)$ (here $H(\alpha, E) = \dim_K E^{(\alpha)}$) and $H(\alpha, L)$ as polynomials (for large α) are related to the expression of $H(\alpha, E \otimes_R L)$ as a polynomial (for large α). This reduces to the standard theory when $p = 1$. The computations involved are lengthy and are of particular interest to the specialist.

Wong, Edward T. 5864

Atomic quasi-injective modules.

J. Math. Kyoto Univ. **3** (1963/64), 295–303.

If R is a ring with unity, then a unital module ${}_RM$ is called quasi-injective if for every submodule N of M and every $f \in \operatorname{Hom}({}_RN, {}_RM)$, f can be extended to an element of $\operatorname{Hom}({}_RM, {}_RM)$. This paper extends some of the results of the reviewer and the author [J. London Math. Soc. **36** (1961), 260–268; MR **24** #A1295] to rings having an atomic lattice of closed right ideals.

R. E. Johnson (Rochester, N.Y.)

Kanzaki, Teruo 5865

On commutator rings and Galois theory of separable algebras.

Osaka J. Math. **1** (1964), 103–115; *correction, ibid.* **1** (1964), 253.

The author generalizes the definition of the word "Galois" due to Auslander and Goldman [Trans. Amer. Math. Soc. 97 (1960), 367–409; MR 22 #12130] to the non-commutative case. Let S be a ring, G a finite group of automorphisms of S, and $R = S^G$. Consider S as a right R-module. Then there is a natural homomorphism, j, of the trivial crossed product of S and G to $\mathrm{Hom}_R(S, S)$. S is called a Galois extension of R if j is an isomorphism and if S is a finitely generated projective right R-module. Before doing Galois theory proper, the author studies the centralizers of Azumaya subalgebras of central Azumaya algebras. He generalizes the relevant result of Auslander and Goldman [loc. cit.] to yield a theorem as satisfactory in this case as the one for simple algebras over fields. He then goes on to study the basic properties of Galois extensions along the lines of the cited paper by Auslander and Goldman, and proves, inter alia, that if H is a subgroup of G and $T = S^H$, then S is a Galois extension of T. For the rest of the paper the author assumes that S is a central Azumaya C-algebra, that no element of G induces the identity on C, and that C is a Galois extension of C^G. He then shows that in order that S be Galois over R, it suffices to suppose that the trivial crossed product of S with G is an Azumaya algebra. He ends up by proving a "fundamental theorem of Galois theory", but, unfortunately has to assume that C is an integral domain for the harder half. Since the author's assumption excludes inner automorphisms, this theory cannot, as yet, be regarded as a true generalization of the Galois theory of simple algebras as presented, e.g., in Jacobson [*Structure of rings*, Amer. Math. Soc., Providence, R.I., 1956; MR 18, 373].

A. Rosenberg (Ithaca, N.Y.)

Bleicher, Michael N.; Schneider, Hans 5866

The decomposition of cones in modules over ordered rings.

J. Algebra 1 (1964), 233–258.

On considère un A-module unitaire à gauche sur un anneau totalement ordonné A. On dit qu'un sous-ensemble P de E est un cône si on a $0 \in P$, $P + P \subseteq P$ et $aP \subseteq P$ $(a \geqq 0)$. On voit alors qu'un cône est convexe. Par définition un cône est propre s'il n'a pas de sous-modules non nuls et un cône est premier s'il n'est pas somme directe de deux cônes propres. L'ensemble des sous-cônes d'un cône propre S qui sont facteurs directs de S forme une algèbre de Boole. Dans le cas où A satisfait à la condition de chaîne ascendante et E à la même condition pour ses facteurs directs, tout sous-cône propre de E admet une décomposition première finie. On introduit la notion de PF-module: module sur un anneau ordonné tel que chaque cône propre contienne un élément libre. On établit alors que le cône des matrices hermitiennes semi-définies est premier. *J. Guérindon* (Rennes)

Hayes, Allan 5867

A representation theory for a class of partially ordered rings.

Pacific J. Math. 14 (1964), 957–968.

This paper presents three theorems on commutative partially ordered rings (po-rings), two of which generalize standard results on lattice-ordered rings. The first is a characterization of those po-rings A which are subdirect unions of ordered rings without non-zero nilpotent elements. The condition for A to be such a ring is that the positive cone A^+ contain all squares and have the property that if $a \notin A^+$, then $pa - a^{2n} \notin A^+$ for all $p \in A^+$ and $n > 0$. A ring with this property is called an f^*-ring. The second main theorem involves the following definition. A po-ring A is called r-Archimedean if, whenever $na + pa \leq b$ holds for all integers $n \geqq 0$ and $p \in A^+$, then $a \leqq 0$. It is shown that an r-Archimedean f^*-ring is a subdirect union of r-Archimedean ordered rings without non-zero nilpotent elements, and conversely. The last main theorem is the analogue of a result of Johnson's [Proc. London Math. Soc. (3) 12 (1962), 207–225; MR 25 #5082]: an Archimedean ordered f^*-ring is isomorphic to a ring of extended real-valued ($R \cup \{\pm\infty\}$) functions which are finite on dense open sets of a locally compact Hausdorff space. *R. S. Pierce* (Seattle, Wash.)

Almeida Costa, A. 5868

Sur la théorie générale des demi-anneaux.

Publ. Math. Debrecen 10 (1963), 14–29.

An algebraic system with two binary compositions (sum and product) is a semi-ring ("demi-anneau") if it is an additive semi-group and a multplicative semi-group with left- and right-distributive laws. Ideals, m-systems, and p-systems are defined, and properties analogous to those concerning the similarly named concepts in rings are demonstrated for general semi-rings. Some sharper results are obtained for ordered semi-rings (with lattice structure such that for all x, y, $x + y = x \vee y$ and $xy \leqq x \wedge y$). The notion of μ-system of ideals is introduced, and the fact that for any semi-ring the semi-ring of its ideals (with operations suitably defined) is ordered becomes a useful tool in investigating the ideal structure of semi-rings. This is particularly true for "μ-semi-rings", a concept analogous to the concept "μ-ring" investigated in a previous paper of the author [Univ. Lisboa Revista Fac. Ci. A (2) 8 (1960), 131–144; MR 26 #2459]. For this class of semi-rings, a body of theorems resembling those of the earlier paper is derived. *W. R. Ballard* (Missoula, Mont.)

Koch, H. 5869

Über Halbkörper, die in algebraischen Zahlkörpern enthalten sind.

Acta Math. Acad. Sci. Hungar. 15 (1964), 439–444.

Let P $[R]$ be the field of all rational [real] numbers, K a finite extension of P. Theorems: Every semi-field $H \subset K$ is simple; If K is minimal with respect to $K \supset H$ and if $0 \in H$, then there exists a set Φ of isomorphisms $\varphi : K \to R$ such that H consists exactly of all $b \in K$ with $\varphi(b) \geqq 0$ for all $\varphi \in \Phi$. Let a be some generator of $K \mid P$, $b \in K$. Let every isomorphism $\varphi : K \to R$ satisfy $\varphi(b) > 0$ or $\varphi(a) < 0$. Then there exists a rational function $r(x)$ with non-negative rational coefficients such that $b = r(a)$.

K. Drbohlav (Prague)

NON-ASSOCIATIVE ALGEBRA

Chawla, L. M. 5870

An interpretation of Rees' exchange algebras in relation to the nuclei of a non-associative linear algebra.

J. Natur. Sci. and Math. 3 (1963), 147–162.

Let $M(x_1, \cdots, x_r)$ be a multilinear form on the vector spaces $V_1, \cdots, V_r$ over the field F. Let $E_{ij}(M)$ be the set of all linear transformations U on V_i such that there is a linear transformation U^1 on V_j with

$$M(x_1, \cdots, x_iU, \cdots, x_r) = M(x_1, \cdots, x_jU^1, \cdots, x_r).$$

Each $E_{ij}(M)$ is an algebra known as an exchange algebra of M. These algebras were first studied by Rees [same J. 1 (1961), no. 1, 57–70; MR 27 #2517].

Each non-associative algebra A has various multilinear forms associated with it. In particular, a trilinear form M defined by Bruck [Trans. Amer. Math. Soc. 56 (1944), 141–199; MR 6, 116] in terms of the multiplicative constants of A is associated with A. If N_μ, N_λ and N_ρ are the middle nucleus, left nucleus and right nucleus of A, respectively, then it is shown that t is an element of N_μ if and only if R_t belongs to $E_{12}(M)$; t is an element of N_λ if and only if L_t belongs to $E_{13}(M)$ and t is an element of N_ρ if and only if R_t is an element of $E_{23}(M)$. Similar relationships are demonstrated between the various intersections of the nuclei of A and the exchange algebras of a quartic form and a pentic form on A. Various other forms on A are examined. *R. H. Oehmke* (Princeton, N.J.)

Herstein, I. N. 5871

Sugli anelli semplici alternativi.

Rend. Mat. e Appl. (5) **23** (1964), 9–13.

A (not necessarily associative) algebra A over a field F is called a composition algebra if it admits a non-degenerate quadratic form g such that $g(xy) = g(x)g(y)$. It is known that such algebras have $[A:F] = 1, 2, 4$, or 8; a simple proof may be found in Jacobson [Rend. Circ. Mat. Palermo (2) 7 (1958), 55–80; MR 21 #66]. It has also been shown by Kaplansky [Proc. Amer. Math. Soc. 4 (1953), 956–960; MR 15, 596] that a composition algebra is, with some trivial exceptions, a simple alternative ring. In this note, which is an announcement of results of which detailed proofs will appear later, the author shows how the theory of simple non-associative alternative rings may be subsumed under that of composition algebras. This yields an alternative proof of a theorem of Kleinfeld [Ann. of Math. (2) 58 (1953), 544–547; MR 15, 392] that such a ring is a Cayley-Dickson algebra. More precisely, the author sketches a proof of the fact that a simple non-associative alternative ring of characteristic $\neq 2$ is an algebra over a field F, and that every element satisfies a quadratic equation with coefficients in F. The constant term then yields the desired quadratic form. *A. Rosenberg* (Ithaca, N.Y.)

Kleinfeld, Erwin 5872

Classification theorems of simple non-associative rings with some applications to projective planes.

Rend. Mat. e Appl. (5) **23** (1964), 4–8.

The author discusses the relationship between the existence of projective planes and the existence of non-associative division rings. Some of the recent developments in the determination of the simple rings in certain classes of non-associative rings are outlined. It is indicated how these results determine the existence of classes of projective planes and the importance, from the point of view of projective planes, of obtaining further results on certain classes of simple rings. *R. H. Oehmke* (Princeton, N.J.)

HOMOLOGICAL ALGEBRA

See also 5814, 5856, 5859, 5865, 5905, 5906, 5949, 5950, 5952, 5960.

Dedecker, Paul 5873

Les foncteurs $\mathscr{E}xt_\Pi$, $\mathbf{H}_\Pi{}^2$ et $H_\Pi{}^2$ non abéliens.

C. R. Acad. Sci. Paris **258** (1964), 4891–4894.

In the usual theory of extensions of groups one classifies short exact sequences

$$0 \to H \to E \to G \to 0,$$

where G and H are given, and which induce a specific action of G on H, i.e., a specific homomorphism φ of G into the quotient group of automorphisms of G by inner automorphisms. In the present paper the group of automorphisms is replaced by an arbitrary group Π, together with a crossed Π-module structure on H. The study of Π-extensions generalizes the study of ordinary extensions of G by H for all possible actions. The resulting "global" classification theorems are in terms of groupoids and principal sets over groups (octopi) and probably take account of all the structure that is to be found in the extension problem. *J. W. Gray* (Urbana, Ill.)

Deheuvels, René 5874

Homologie des ensembles ordonnés et des espaces topologiques.

Bull. Soc. Math. France **90** (1962), 261–321.

Importante contribution à l'algèbre homologique classique permettant, entre autres, de définir une homologie d'un espace à valeurs dans un préfaisceau et une cohomologie à valeurs dans un cofaisceau. Ce mémoire développe une note précédente [C. R. Acad. Sci. Paris **250** (1960), 2492–2494; MR **26** #1884]. Les questions traitées pourraient actuellement être généralisées en tenant compte des résultats récents de Grothendieck et ses élèves sur les topologies et les faisceaux. Voir, par exemple, Michael Artin [*Grothendieck topologies* (mimeographed notes), Harvard, 1962] et Michel Demazure [Topologies et faisceaux, Séminaire de Géométrie Algébrique, Inst. Hautes Études Sci. Publ. Math., 1963].

L'auteur part du fait que la théorie de Čech repose sur la structure d'ordre de l'ensemble des ouverts d'un espace topologique. Sur un ensemble ordonné $\mathscr{E}$, $\preccurlyeq$ considéré comme catégorie (les morphismes $a \to b$, $a, b \in \mathscr{E}$, étant les relations $a \preccurlyeq b$), un système covariant [contravariant] A de coefficients est un foncteur de même variance $A: \mathscr{E} \to \mathscr{C}$ où $\mathscr{C}$ est une catégorie abélienne. Soit $\mathscr{C}(\mathscr{E})[\mathscr{C}^*(\mathscr{E})]$ la catégorie dont les objets sont de tels systèmes covariants [contravariants]. Si $\mathscr{C}$ est suffisamment raisonnable on définit des foncteurs sections $\Gamma: \mathscr{C}(\mathscr{E}) \to \mathscr{C}$, et co-sections $L: \mathscr{C}(\mathscr{E}) \to \mathscr{C}$, solutions de problèmes universels duaux. Les dérivés à droite $r^n\Gamma$ et à gauche l^nL fournissent alors la cohomologie $H^n(\mathscr{E}, -): \mathscr{C}(\mathscr{E}) \to \mathscr{C}$, et l'homologie $H_n(\mathscr{E}, -): \mathscr{C}(\mathscr{E}) \to \mathscr{C}$ à valeurs dans un système de coefficients $A \in \mathscr{C}(\mathscr{E})$. Dualement pour $A \in \mathscr{C}^*(\mathscr{E})$.

L'une des principales applications consiste à associer à tout ensemble ordonné $\mathscr{E}$ un schéma simplicial $K = K(\mathscr{E})$ et à tout schéma simplicial K un ensemble ordonné $\mathscr{E} = \mathscr{E}(K)$. Cela est fait de telle manière que coïncident l'homologie des $\mathscr{E}$ et K à valeurs dans un système contravariant de coefficients ainsi que la cohomologie à valeurs dans un système covariant, les seules qui soient

définies pour un schéma simplicial K. Il devient donc possible de définir l'homologie et la cohomologie de K à valeurs dans un système A, quelle que soit sa variance; d'où par exemple l'homologie d'un espace à valeurs dans un préfaisceau.

Parmi les notions fondamentales mentionnons celle d'"ordre" ρ d'un ensemble ordonné $\mathscr{E}$ dans un autre $\mathscr{E}'$: Il s'agit essentiellement d'un ordre sur la somme disjointe $\mathscr{E} \cup \mathscr{E}'$ tel qu'aucun élément de $\mathscr{E}'$ ne précède un élément de $\mathscr{E}$. Toute application croissante $\lambda: \mathscr{E} \to \mathscr{E}'$ définit un tel ordre ρ_λ. Un "morphisme au-dessus de ρ" entre système $A \in \mathscr{C}(\mathscr{E})$ et $A' \in \mathscr{C}(\mathscr{E}')$ est essentiellement un système B sur l'ordre ρ de $\mathscr{E} \cup \mathscr{E}'$. Un morphisme au-dessus de ρ_λ correspond à une transformation naturelle du foncteur A dans le foncteur $A' \circ \lambda$. Ces notions jouent un rôle essentiel dans les théorèmes d'unicité. Fondamentale aussi est la notion d'"hyperdérivé" d'un foncteur composé

$$G \circ F: \mathscr{C} \to \mathscr{C}' \to \mathscr{C}''.$$

Pour $A \in \mathscr{C}(A)$ on considère des résolutions projective $\mathscr{P}A$ et injective $\mathscr{J}A$ d'où des $\mathscr{C}'$-complexes $F\mathscr{P}A$, $F\mathscr{J}A$. En en prenant à nouveau des résolutions on obtient alors quatre $\mathscr{C}''$-complexes $G\mathscr{P}F\mathscr{P}A$, $G\mathscr{P}F\mathscr{J}A$, $G\mathscr{J}F\mathscr{P}A$, $G\mathscr{J}F\mathscr{J}A$ dont l'homologie fournit par définition les hyperdérivés du foncteur GF. Par exemple $(lr)_nGF(A) = H^n(G\mathscr{P}F\mathscr{J}A)$. Exemple parmi les théorèmes: Sur un espace X on note $\mathscr{E}$ l'ensemble ordonné de ses ouverts et $\mathscr{F}$ une sous-famille de $\mathscr{E}$ suffisamment riche. D'où un ordre canonique π de $\mathscr{E}$ dans $\mathscr{F}$. Soit d'autre part $A \in \mathscr{C}(\mathscr{E})$ un préfaisceau sur X, $\mathscr{C}$ étant une catégorie abélienne AB5 au sens de A. Grothendieck [Tôhoku Math. J. (2) **9** (1957), 119–221; MR **21** #1328]. Alors l'homologie de X à valeurs dans A se calcule au moyen des cochaînes de $\mathscr{F}$ à valeurs dans πA.

Un mémoire complémentaire est annoncé devant étudier la dualité homologie-cohomologie et les relations avec la théorie de Borel-Moore: Homologie à coefficients dans un faisceau sur un espace localement compact.

P. Dedecker (Lille)

Ehresmann, Charles 5875

Groupoïdes sous-inductifs.

Ann. Inst. Fourier (Grenoble) **13** (1963), *fasc.* 2, 1–60.

From the introduction: "Les principaux résultats de ce mémoire sont: l'existence et les propriétés des groupoïdes sous-préinductifs des atlas faibles complets et des atlas complets attachés à un groupoïde sous-préinductif; les théorèmes de complétion d'un groupoïde prélocal; les théorèmes d'existence du groupoïde sous-inductif des filtres sur un groupoïde sous-préinductif. Cet article est une généralisation, et une étude plus approfondie, de la théorie des groupoïdes inductifs, qui interviennent dans de nombreuses questions; il peut donc être considéré comme la suite d'un article antérieur [mêmes Ann. **10** (1960), 307–332; MR **22** #8525]."

Enochs, Edgar 58

Torsion free covering modules.

Proc. Amer. Math. Soc. **14** (1963), 884–889.

For R an integral domain, let E be any R-module. By torsion-free cover of E is meant a torsion-free R-modu $T(E)$, together with a homomorphism t_E from $T(E)$ to such that (1) every homomorphism from every torsic free R-module F to E factors through $T(E)$, and (2) t kernel of t_E contains no non-zero pure submodules of $T($ It is proved that there exists one and, up to ismorphis only one torsion-free cover of E. If K is the kernel of then it is shown that $0 \to \mathrm{Ext}_R{}^i(F, K) \to \mathrm{Ext}_R{}^i(F, T(E))$ $\mathrm{Ext}_R{}^i(F, E) \to 0$ is exact for every integer i and torsion-fr R-module F. If M is a maximal ideal of R and T $T(R/M)$ is a submodule of a torsion-free R-module F, wi $T \cap (M \cdot F) = M \cdot T$, then T is a direct summand of Hence T is a sort of M-adic integer. In particular, for the integers, the projective cover of a cyclic group of or p is the p-adic integers. The elegance of the meth remind this reviewer of the construction of inject envelopes. *D. K. Harada, Manabu 58

Structure of hereditary orders over local rings.

J. Math. Osaka City Univ. **14** (1963), 1–22.

Let R be a discrete rank one valuation ring of a field and let Σ be a central simple K-algebra. A subring Γ o is called an h-order if Γ is an order of R in Σ (i.e., $\Gamma \cdot K = \Sigma$, $\Gamma \supset R$, and Γ is finitely generated as an module) and if Γ is hereditary (every left ideal of Γ is p jective). These are of interest since Auslander and Go man proved that an order Γ is a maximal order (the ord ordered by inclusion; maximal orders always exist and unique up to isomorphism) if and only if Γ is an h-or with $\Gamma/\mathrm{rad}(\Gamma)$ a simple ring. In the present note a s prisingly complete theory is given for all h-orders. It proved that all maximal chains of h-orders have fi length, and in fact the same length; call it n. Let Γ be h-order. Let $N = \mathrm{rad}(\Gamma)$, the radical of Γ. Then Γ/N i direct sum of full matrix rings over division rings, these division rings are isomorphic to a fixed division r Δ, so we may write $\Gamma/N \simeq \Delta_{m_1} \oplus \cdots \oplus \Delta_{m_r}$ (where Δ_m is ring of m-by-m matrices over Δ). For $i = 1, \cdots, r$ let M_i the maximal ideal of Γ which consists of all $x \in \Gamma$ such t the ith component of $x + N \in \Gamma/N$ is zero in the ab

breakdown of Γ/N. Let N^{-1} be the set of $y\in\Sigma$ with $NyN\subset\Gamma$. Then $N^{-1}M_1N, N^{-2}M_1N^2, \cdots, N^{-s-1}M_1N^{s+1}$ is proven to be the set of all maximal ideals of Γ, so, after re-indexing if necessary, we may assume that $M_2=N^{-1}M_1N$, $M_3=N^{-2}M_1N^2$, etc. We agree to distinguish r-tuples only up to cyclic permutations (so

$$(m_1, m_2, \cdots, m_r) = (m_2, \cdots, m_r, m_1),$$

for instance). With this agreement, $(m_1, \cdots, m_r)$ is independent of the indexing and so is an invariant of Γ; it is called the form of Γ. $m_1, m_2, \cdots, m_r$ are positive integers and it is proven that $m_1+m_2+\cdots+m_r=n$. Conversely, if $k_1, k_2, \cdots, k_s$ are positive integers with $k_1+k_2+\cdots+k_s=n$, then it is proven that there is an h-order which has $(k_1, k_2, \cdots, k_s)$ for form. Most important of all, two h-orders are isomorphic if and only if they have the same form. The maximal orders are the ones with form (n). The minimal h-orders are the ones with form $(1, 1, \cdots, 1)$. Hence, minimal h-orders always exist, and they are all isomorphic. An h-order Γ has a constant form $(t, t, \cdots, t)$ if and only if $\mathrm{rad}(\Gamma)$ is a principal ideal. Other ramifications are given. *D. K. Harrison* (Eugene, Ore.)

Harada, Manabu 5880c

Hereditary orders which are dual.

J. Math. Osaka City Univ. **14** (1963), 107–115.

Hereditary orders, introduced by Auslander and Goldman [Trans. Amer. Math. Soc. **97** (1960), 1–24; MR **22** #8034], were first studied by the author in his thesis [ibid. **107** (1963), 273–290; MR **27** #1474], and their structures were completely determined (modulo knowledge of maximal orders) by the reviewer in his thesis [Ph.D. Dissertation, Princeton Univ., Princeton, N.J., 1963; Bull. Amer. Math. Soc. **69** (1963), 721–724; MR **27** #2543].

In the first paper, the author studies hereditary orders in quaternion algebras over the rationals, using the known structure of maximal orders in this case. In the second, the author generalizes successfully all of Deuring's definitions and results on maximal orders (of non-arithmetic nature): normal ideals, characteristic products, ideal class group, discriminant [Deuring, *Algebren*, Springer, Berlin, 1935]. The starting point of the third is the reviewer's observation (in his thesis) that the endomorphism ring of a projective module over an hereditary order is also hereditary; the consequences are fully investigated.

A. Brumer (Ann Arbor, Mich.)

Ito, Yoshihiko 5881

On relative cohomology group of groups. (Japanese. English summary)

Sci. Rep. Fac. Lib. Arts Ed. Gifu Univ. Natur. Sci. **3** (1962/63), 155–160.

The author gives the cup-product of Adamson's relative cohomolgy groups. Let G be an abelian group, H_i $(i=1, 2)$ subgroups, $H_3=H_1\cap H_2$, $\bar G=G(Z)$ the group ring of G over the rational integer ring Z, and A and $B\bar G$-modules, respectively.

He shows existence of a $\bar G$-homomorphism $\varphi_{r,s}$ of the $(r+s)$-relative chain group $C_{r+s}(G:H_3)$ into $C_r(G:H_1)\otimes C_s(G:H_2)$ such that $\varphi_{r,s}\partial^3_{r+s-1}=\partial'_{r+1}\varphi_{r+1,s}+\partial''_{s+1}\varphi_{r,s+1}$ and $(\varepsilon_1\otimes\varepsilon_2)\varphi_{0,0}=\varepsilon_3$, where ε_i denotes the usual mapping of $C_0(G:H)$ into Z, $\partial_r'=\partial_r^1\otimes 1_s$, and $\partial_s''=(-1)^r(1_r\otimes\partial_s^2)$. Then he obtains the cup-product $\cup$ of $H^r([G:H_1], A)$ and $H^s([G:H_2], B)$ into $H^{r+s}([G:H_3], A\otimes B)$ naturally.

Sur les modules plats.

C. R. Acad. Sci. Paris **258** (1964), 6313–6316.

It is proven that in the category of left unitary modules over a unitary ring, a module M is flat if and only if it is the inductive limit of a directed system of free modules of finite type. A number of consequences are mentioned for tensor, symmetric, and exterior algebras.

J. W. Gray (Urbana, Ill.)

Nakayama, T. 5884

Class group of cohomologically trivial modules and cyclotomic ideals.

Acta Arith. **9** (1964), 245–256.

If Λ is a left Noetherian ring, $\mathfrak{P}$ the category of finitely generated left Λ-modules and $\mathfrak{F}$ that of finitely generated left Λ-modules of finite projective dimension, then the inclusion $\mathfrak{P}\subset\mathfrak{F}$ induces $\mathfrak{G}\mathfrak{P}\approx\mathfrak{G}\mathfrak{F}$, where $\mathfrak{G}$ is the Grothendieck group. In the special case that Λ is the integer group ring of a finite group, then $\mathfrak{F}$ just contains the cohomologically trivial modules.

But further, Swan [Ann. of Math. (2) **71** (1960), 552–578; MR **25** #2131] showed that if $P\in\mathfrak{P}$, then $Q\otimes P$ is free. Thus the inclusion $\mathfrak{R}\subset\mathfrak{F}$, where $\mathfrak{R}$ is the category of finite cohomologically trivial Λ-modules, induces a homomorphism $\mathfrak{G}\mathfrak{R}\to\mathfrak{G}\mathfrak{P}$ whose image consists precisely of the projective class group $\mathfrak{C}\mathfrak{P}$, regarded as the subgroup of $\mathfrak{G}\mathfrak{P}$ of elements of virtual rank 0.

These observations are used to make explicit computations in case the group is of prime order, the elements of $\mathfrak{C}\mathfrak{P}$ then being represented by ideals in the cyclotomic field [Rim, ibid. (2) **69** (1959), 700–712; MR **21** #3474].

Sur les décompositions de morphismes dans les catégories à sommes ou à produits fibrés.

C. R. Acad. Sci. Paris **258** (1964), 6317–6319.

This paper should include a reference to Grothendieck

[*Séminaire Bourbaki*, 1959/60, Exp. 190, Secrétariat mathématique, Paris, 1960; MR 23 #A2273], where one can find most of the remarks concerning normal monomorphisms (essentially strict monomorphisms), universal monomorphisms, their duals, and the relations between these notions and fibre products and sums. In this context, the weak image of a morphism is defined to be the fibre product of the sub-objects of the range through which the morphism factors. An epimorphism is called strong if its image is its range. This gives a unique decomposition of an arbitrary morphism into the composition of a strong epimorphism and a monomorphism. Under suitable conditions this decomposition has the expected desirable properties. *J. W. Gray* (Urbana, Ill.)

Sonner, Johann 5886

Universal solutions and adjoint homomorphisms.

Math. Z. **86** (1964), 14–20.

The author discusses the relation between the solution of left universal (= co-universal) and right universal problems, and adjoint homomorphisms. Thus if $\mathscr{A}$ and $\mathscr{B}$ are categories and F is a functor from $\mathscr{A}^0 \times \mathscr{B}$ to the category $\mathfrak{St}$ of sets and mappings, then there is a universal map for each $\mathscr{A}$-object a if and only if the identity mapping of $\mathscr{B}$ admits a left adjoint. Examples (which, it is claimed, cannot be treated by previous methods) include symmetric and exterior algebras and tensor products of pairs of modules (over a commutative coefficient ring).

★Topics in Abelian groups. 5888

Proceedings of the Symposium on Abelian Groups, held at New Mexico State University, June 4–8, 1962. Edited by J. M. Irwin and E. A. Walker.

Scott, Foresman and Co., Chicago, Ill., 1963. 368 pp. $6.00.

The papers contained in this volume will be reviewed individually. There is a list of 30 unsolved problems presented at the symposium, together with an account (pp. 357–364) of the present status of the 86 unsolved problems stated by L. Fuchs in his book [*Abelian groups*, Publ. House Hungar. Acad. Sci., Budapest, 1958; MR 21 #5672].

Hall, Marshall, Jr.; Senior, James K. 5889

★The groups of order 2^n ($n \le 6$).

The Macmillan Co., New York; Collier-Macmillan, Ltd., London, 1964. 225 pp. $15.00.

The ambitious task the authors set themselves in this b is the determination of all groups of order 2^n, where n: They not only succeed, but also supply us with a great of information about the groups on their list. For $n =$ and 3 these groups are, of course, well known. It turns that there are 14 groups of order 16, 51 of order 32, 267 of order 64.

The classification begins with the notion of "fam which was introduced by Philip Hall [J. Reine Ang Math. **182** (1940), 130–141; MR **2**, 211]. For a group G $Z(G)$ and $[G, G]$ denote the center of G and the c mutator subgroup of G, respectively. The natural from $G \times G$ to $[G, G]$ lifts to a map from $G/Z(G) \times G/Z$ to $[G, G]$. Call this map φ. For another group G' call corresponding map φ'. Then G and G' are said to bel to the same family if there exist isomorphisms ρ of G/Z with $G'/Z(G')$ and λ of $[G, G]$ with $[G', G']$ such $\varphi' \circ \rho \times \rho = \lambda \circ \varphi$. "Belonging to the same family" is cle an equivalence relation. The groups under considera fall into 27 families. The procedure is first to determine families which can occur, and then to classify the gro which occur within each family. Of these two tasks first is apparently the more difficult. It is accomplis with the use of Schur's theory of the multiplier of a gr [I. Schur, ibid. **127** (1904), 20–50].

A careful reading of the first chapter, which deals definitions and notation, is sufficient to enable the rea to use the tables. The remaining chapters deal with theory which leads to the classification.

The first tables deal with family invariants, i.e., th invariants of a group which depend only on the famil which the group belongs. The length of the lower cen series is an example. Following these are tables which the groups of order 2^n, $n \le 6$, in each of the 27 fami The groups are given by generators and relations. For group we are supplied, among other things, with the n ber of elements of each order, and the order of the a morphism group.

Finally, there are 130 pages of lattice diagrams gi abundant information about the lattice of normal groups of all the various groups under consideration.

The format of this book is rather unusual. The dim sions are 14 inches high, 17 inches wide, and ½ inch th It is interesting to conjecture about the eventual loca of the book in a typical library. Moreover, the first pages have three pages per page. More precisely, the ten sides have three columns, each column being giv page number. Thus the eleventh side turns out to be 31.

Undoubtedly this book will serve as a useful tes ground for group-theoretical conjectures. It is perhaps fortunate that the testing ground has such extrem awkward dimensions. *Michael Rosen* (Providence,

Fridman, A. A.

Degrees of unsolvability of the word problem for fin presented groups. (Russian)

Dokl. Akad. Nauk SSSR **147** (1962), 805–808.

The main theorem of this important paper is that, g any recursively enumerable degree of unsolvability α, can effectively find a finitely presented group whose problem is of degree α. The proof, outlined in the pa proceeds more or less as follows.

A Turing machine with a halting-type problem

degree α is constructed. The author then constructs a semi-group for which the problem of equality to a fixed generator q is of degree α. Finally, following W. W. Boone [Ann. of Math. (2) **70** (1959), 207–265], the author constructs the required group B. The difficulty is in showing that the word problem for B reduces to the above-mentioned problem for the semi-group. This is accomplished by (1) solving the word problem for the group G obtained from B by removing the defining relation $q^{-1}tqk = kq^{-1}tq$, and (2) considering a variation of the extended word problem in B relative to the subgroup generated by all generators other than k. *M. Greendlinger* (Ivanovo)

Britton, John L. 5891

The word problem.

Ann. of Math. (2) **77** (1963), 16–32.

The proof given in this paper for P. S. Novikoff's theorem on the unsolvability of the word problem for groups is the simplest so far published, certainly for those familiar with free products with amalgamated subgroups. This is the main tool in the proof of the following principal lemma.

Let G be obtained from H by adding the generators p_i and the defining relations $p_i^{-1}A_{i,j}p_i = B_{i,j}$, where for every fixed i the mapping in H determined by $A_{i,j} \to B_{i,j}$ is an isomorphism. If $w = 1$ in G and contains at least one of the p_i, then w contains a subword $p_a^{-1}Cp_a$ [or $p_aCp_a^{-1}$], where C belongs to the subgroup of H generated by the $A_{a,j}$ [or the $B_{a,j}$].

The group proven to have an unsolvable word problem is virtually the same as in W. W. Boone [same Ann. (2) **70** (1959), 207–265]. However, here the author builds it up from a free group in five stages along the lines suggested by the principal lemma. Repeated application of the latter, together with some intricate uses of induction, yields the desired result.

Über ein spezielles dreifaches schiefes Produkt.

Acta Sci. Math. (*Szeged*) **25** (1964), 143–148.

Das dreifache schiefe Produkt $\mathfrak{G} \circ \Gamma \circ G$ der Gruppen $\mathfrak{G} = (a, b, \cdots)$, $\Gamma = (\alpha, \beta, \cdots)$, $G = (A, B, \cdots)$ hat die Multiplicationsvorschrift

$$(a, \alpha, A)(b, \beta, B) = (ab^{\alpha}, \alpha\beta^{A}, AB^{a}),$$

wobei b^{α}, β^{A}, B^{a} drei beliebige Funktionen mit Werten in $\mathfrak{G}$, Γ, G bezeichnen. Mit den Anfangsbedingungen

$$a^{\varepsilon} = a; \qquad \alpha^{E} = \alpha; \qquad A^{e} = A;$$
$$e^{\alpha} = e; \qquad \varepsilon^{A} = \varepsilon; \qquad E^{a} = E,$$

für beliebige $a \in \mathfrak{G}$, $\alpha \in \Gamma$, $A \in G$ und für $e \in \mathfrak{G}$, $\varepsilon \in \Gamma$, $E \in G$ beweist der Verfasser dass $\mathfrak{G} \circ \Gamma \circ G$ eine Gruppe bildet dann, und nur dann wenn die folgenden Relationen erfüllt sind: für alle $a, b, c, \alpha, \beta, \gamma, A, B, C$

$$(1) \quad \begin{array}{lll} (bc)^{\alpha} = b^{\alpha}c^{\alpha}; & (\beta\gamma)^{A} = \beta^{A}\gamma^{A}; & (BC)^{a} = B^{a}C^{a}; \\ (c^{\beta})^{\alpha} = c^{\alpha\beta}; & (\gamma^{B})^{A} = \gamma^{AB}; & (C^{b})^{a} = C^{ab}; \\ c^{\beta^{A}} = c^{\beta}; & \gamma^{B^{a}} = \gamma^{B}; & C^{b^{\alpha}} = C^{b}. \end{array}$$

Definiert man die zulässigen Normalteiler $\mathfrak{G}_1$, Γ_1, G_1 von $\mathfrak{G}$, Γ, G durch $\mathfrak{G}_1 = (a \mid a \in \mathfrak{G},\ A^{a} = A$ für alle $A \in G)$, usw., ergibt dann den zweiten Satz so:

$$\mathfrak{G} \circ \Gamma \circ G/(\mathfrak{G}_1, \Gamma_1, G_1) \cong \mathfrak{G}/\mathfrak{G}_1 \times \Gamma/\Gamma_1 \times G/G_1$$

mit $(\mathfrak{G}_1, \Gamma_1, G_1) \cong \mathfrak{G}_1 \times \Gamma_1 \times G_1$ d.h. $\mathfrak{G} \circ \Gamma \circ G$ ist isomorph zu einer Schreierschen Erweiterung von $\mathfrak{G}_1 \times \Gamma_1 \times G_1$ durch $\mathfrak{G}/\mathfrak{G}_1 \times \Gamma/\Gamma_1 \times G/G_1$. *V. S. Krishnan* (Madras)

Hancock, V. Ray 5894

Commutative Schreier semigroup extensions of a group.

Acta Sci. Math. (*Szeged*) **25** (1964), 129–134.

The paper continues the study of complete structures [Wiegandt, Acta Sci. Math. (Szeged) **19** (1958), 93–97; MR **20** #2387; ibid. **19** (1958), 219–223, MR **20** #6476; the author, Proc. Amer. Math. Soc. **11** (1960), 71–76; MR **22** #4787]. The main theorem is that if S is a group, Q a commutative semigroup with identity element, Q' the maximal cancellative homomorphic image of Q, and Q^* the difference-group of Q', then the group of equivalence classes of commutative Schreier extensions of S by Q is isomorphic to, and can be obtained from, the group of commutative group extensions of S by Q^*. An immediate consequence of this theorem is that a commutative semigroup is complete if and only if it is a divisible group.

On the factorization of finite groups. (Russian)

Ural. Gos. Univ. Mat. Zap. **3**, *tetrad* 3, 3–17 (1962).

Expository article. First factorizations into cyclic, Abelian, nilpotent and solvable factors are considered. Then the orders of the factors are subject to certain conditions or one of the factors is assumed to be a normal subgroup. *L. Fuchs* (Budapest)

Azleckiĭ, S. P. 5896

On the theory of π-special groups. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 969–975.

A finite group G is π-special, where π is a set of primes, if G has a normal, nilpotent Hall π-subgroup. Define the π-commutator subgroup $K_\pi(G)$ of G as the subgroup of G generated by all commutators of π-elements of G, the π-Frattini subgroup $\Phi_\pi(G)$ as the intersection of all maximal π-subgroups of G. The author proves the following analogue of a result due to Wielandt: G is π-special if and only if $K_\pi(G) \leq \Phi_\pi(G)$ and $\Phi_\pi(G)$ is nilpotent. The remainder of the article consists of necessary and/or sufficient conditions for a group to be solvable in terms of properties of $H_\pi{}^0$-subgroups, these being refinements of H^0-subgroups introduced by the author in an earlier paper [Ukrain. Mat. Ž. **16** (1964), 220–225; MR **28** #5107].

P. Fong (Berkeley, Calif.)

Morris, A. O. 5897

A note on the multiplication of Hall functions.

J. London Math. Soc. **39** (1964), 481–488.

Pursuing his efforts to make explicit the coefficient in the expansion of a product $Q_{(\lambda)}Q_{(\mu)}$ of two Hall functions, the author succeeds in the special case $Q_{(\lambda)}q_r$ in improving on his previous theorem [Proc. London Math. Soc. (3) **13** (1963), 733–742; MR **27** #3712; cf. also D. E. Littlewood, ibid. (3) **11** (1961), 485–498; MR **24** #A173]. The improvement consists in recognizing that the coefficient f in the expansion

$$Q_{(\lambda)}q_r = \sum_{(\nu)} f^{(\nu)}_{(\lambda)r}(t)Q_{(\nu)}$$

can be written as a product of factors

$$f^{(\nu)}_{(\lambda)r}(t) = \prod_{i=1}^{s} (1-t^{r_i}),$$

with certain further limitations which are natural in the context. In the second part of the paper this theorem is used to simplify the proof of I. J. Davies [Proc. Edinburgh Math. Soc. (2) **13** (1962), 1–4; MR **26** #3780] in the case $(\mu)=(p^r)$. *G. de B. Robinson* (Toronto, Ont.)

Beaumont, R. A.; Pierce, R. S. 5898

Isomorphic direct summands of abelian groups.

Math. Ann. **153** (1964), 21–37.

In a previous paper the authors proved that "most large" abelian groups are isomorphic to a proper direct summand of themselves. In particular, this is true for every torsion group of power greater than the continuum. In this paper they point out that a group G has an isomorphic proper direct summand if and only if there exist φ, θ in the endomorphism ring of G such that $\theta\circ\varphi=1$ and $\varphi\circ\theta\neq 1$. For this reason they make a systematic study of systems $\langle G;\varphi,\theta\rangle$, where G is an abelian group and φ and θ are endomorphisms of G with $\theta\circ\varphi=1$. Such systems are equivalent to Δ-modules, where $\Delta=Z[X,Y]/(XY-1)$. Here $Z[X,Y]$ is the polynomial ring in two non-commuting indeterminates and $(XY-1)$ is the ideal generated by $XY-1$. They show that every Δ-module is naturally an extension of an automorphic module by a shift module, where automorphic and shift modules are of a certain explicit type which may be considered known. For this reason they study $\mathrm{Ext}_\Delta{}^1$. For K an automorphic module and T any module (so possibly a shift module) they construct a seven-term exact sequence which, among other things, pins $\mathrm{Ext}_\Delta{}^1(T,K)$ between $\mathrm{Hom}_Z(T,K)$ and $\mathrm{Ext}_Z(T,K)$, where Z denotes the integers. The maps in this exact sequence are natural, and the condition that they be one-one, onto, etc., is equivalent to certain natural situations in the original problem. The authors now interpret this general theory in special cases and harvest a number of interesting special results.

Fuchs, L. 5899

On algebraically compact abelian groups.

J. Natur. Sci. and Math. **3** (1963), 73–82.

The known properties of algebraically compact abelian groups are presented systematically. The many useful equivalent definitions of this fundamental concept, the Fleischer-Kaplansky characterization by number invariants, and the known relation to cotorsion groups, are all given in the author's usual perspicuous style.

D. K. Harrison (Eugene, Ore.)

Rangaswamy, K. M. 5900

A note on algebraic compact groups.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 369–371.

It is proved that every algebraically compact group is the completion of a direct sum of cyclic groups. Also, a number of conditions on a cotorsion group are given which are equivalent to algebraic compactness. The proofs are homological. *D. K. Harrison* (Eugene, Ore.)

Golema, K.; Hulanicki, A. 5901

The structure of the factor group of the unrestricted sum by the restricted sum of Abelian groups. II.

Fund. Math. **53** (1963/64), 177–185.

Part I (by A. Hulanicki) appeared in Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **10** (1962), 77–80 [MR **26** #5060]. Let $G_1, G_2, G_3, \cdots$ be a sequence of abelian groups whose cardinalities are not greater than that of the continuum. Let S^* be the direct product of these groups, and let S be the direct sum. A well-known theorem of Hulanicki states that S^*/S is algebraically compact. This result is refined in this paper to give necessary and sufficient conditions on a group A that it be isomorphic to S^*/S for some sequence of groups. These conditions are explicit and, although technical, they are not complicated.

Irwin, J. M.; Khabbaz, S. A. 5902

On generating subgroups of Abelian groups.

Proc. Colloq. Abelian Groups (Tihany, 1963), pp. 87–97. *Akadémiai Kiadó, Budapest*, 1964.

The authors call an Abelian group G Σ^n-cyclic when G is generated by n subgroups, each of which is a direct sum of cyclic groups. One of the authors, Khabbaz, submitted a question on the conditions under which Abelian groups are Σ^2-cyclic. J. D. Reid [Proc. Amer. Math. Soc. **13** (1962), 222–225; MR **24** #A3190] gave a solution in the torsion-free case.

In this paper, the authors give a solution in the general case. The main results are as follows: (1) Every reduced p-group is Σ^2-cyclic. (2) A p-group G is Σ^2-cyclic if and only if G is not a finite direct sum of $Z(p^\infty)$'s directly summed with a group of bounded order. (3) A group G is Σ^2-cyclic if and only if (a) G/T (T a maximal torsion subgroup of G) is free of finite rank and T is Σ^2-cyclic or (b) the torsion-free rank of G is infinite. (4) A group G is Σ^n-cyclic for some n if and only if G is Σ^2-cyclic. (5) A p-group G is generated by n of its basic subgroups for some integer n if and only if G is generated by two of its basic subgroups.

Loiko, N. 5903

The S-isomorphism of torsion-free Abelian groups (Russian)

Ural. Gos. Univ. Mat. Zap. **3**, *tetrad'* 1, 67–71 (1961).

For a group G, let $S(G)$ denote the lattice of all cosets of all

subgroups of G together with the empty set, where the intersection is the set-theoretical intersection and the union of the cosets aH, bF ($a, b \in G$; H, F subgroups of G) is aK; here K is the subgroup generated by H, F and $a^{-1}b$. An S-isomorphism φ of G and G_1 is a lattice-isomorphism of $S(G)$ and $S(G_1)$; φ induces a one-to-one mapping between G and G_1, since the elements are cosets of the identities e, e_1. If $\varphi(e) = e_1$ and if G, G_1 are torsion-free Abelian, then this induced mapping is an isomorphism between G and G_1.

Loonstra, F. 5905

A-ordering of the group $\mathrm{Ext}(B, A)$.

Proc. Colloq. Abelian Groups (*Tihany*, 1963), *pp.* 105–114. *Akadémiai Kiadó, Budapest*, 1964.

Let A be an abelian group. By an extension of A is meant a pair (G, α), where G is an abelian group and α is a monomorphism of A into G. Write $(G_1, \alpha_1) < (G_2, \alpha_2)$ for two extensions of A if there exists a homomorphism f from G_1 to G_2 with $\alpha_2 \circ f = \alpha_1$. An extension a is called equivalent to an extension b (of A) if $a < b$ and $b < a$. Then the class $V(A)$ of all equivalence classes of extensions of A is a partially ordered class and, indeed, has all the properties of a lattice except that of being a set. For an abelian group B one can consider all pairs (β, G), where G is an abelian group and β is an epimorphism from G to B, and analogously to the above, develop a lattice-like class $P(B)$. There are obvious natural maps from $\mathrm{Ext}(B, A)$ into $V(A)$ and into $P(B)$. This situation is considered in detail in the special case when A and B are finite.

Levin, Frank 5907

On some varieties of soluble groups. I.

Math. Z. 85 (1964), 369–372.

Let $S \subseteq G$ be a subset of a group, S^G its normal closure. It is proved that—with the usual notation for left-normed commutators—$[s, x, y] = [s, y, x]$ for all $s \in S$, $x, y \in G$, implies the same relation for all $s \in S^G$ and $x, y \in G$. Moreover, the latter is equivalent to $[s, [x, y]] = 1$ for all $s \in S^G$ and $x, y \in G$. It follows that the law

$$[x_1, \cdots, x_n, x_{n+1}, x_{n+2}] = [x_1, \cdots, x_n, x_{n+2}, x_{n+1}]$$

defines the same variety as the law $[x_1, \cdots, x_n, [x_{n+1}, x_{n+2}]] = 1$. The proof uses and extends results by I. D. Macdonald [same Z. 76 (1961), 270–282; MR 24 #A166].

Hanna Neumann (Canberra)

Macdonald, I. D. 5908

Generalisations of a classical theorem about nilpotent groups.

Illinois J. Math. 8 (1964), 556–570.

With skillful manipulation of commutator calculation the author obtains several interesting theorems on finite p-groups. Some of his main results are as follows. (1) Let G be a metabelian p-group of class precisely $2n$ with every proper subgroup of class n. Then $n = 1$. (2) Let G be a group of order p^{r+m} in which every subgroup of order p^r has class n, while G itself is not of class n. Then (i) G has a set of at most $m+n$ generators; (ii) the class of G is bounded by $f(m, n)$, where f is a function of m and n but not of r. (3) Let G be a group of order p^{r+4} in which every subgroup of order p^r has class 2. Then the class of G is 4; and G is metabelian if $p > 2$. Here the author requires some results of Blackburn [Proc. London Math. Soc. (3) 11 (1961), 1–22; MR 23 #A208] and Heineken [Illinois J. Math. 5 (1961), 681–707; MR 24 #A1319]. (4) Let a prime $p \geq 5$ be given. Then there is a p-group of order p^{11} and of class precisely 6 with every proper subgroup having class 3.

The author acknowledges that the results of his paper with T. Taylor [same Proc. 274 (1963), 1–4; MR 28 #3100] were anticipated by A. I. Mal'cev [Ivanov. Gos. Ped. Inst. Učen. Zap. Fiz.-Mat. Nauki 4 (1953), 107–111; MR 17, 825].

Weichsel, Paul M. 5910

A decomposition theory for finite groups with applications to p-groups.

Trans. Amer. Math. Soc. 102 (1962), 218–226.

The author introduces a notion of decomposition for finite groups which includes direct products and subdirect products as special cases. A group G is called an "in-direct product" if G belongs to $\{A_\alpha\}^*$, where $\{A_\alpha\}$ is the set of all proper subgroups and factor groups of G and $\{A_\alpha\}^*$ is the "closure" of the set $\{A_\alpha\}$ which is the smallest set of groups containing $\{A_\alpha\}$ and closed under the operations of taking finite direct products, subgroups, and factor groups. It is shown that an in-direct product which is not a subdirect product or a factor group of a direct product contains a normal subgroup which is an abelian p-group.

This notion is applied to p-groups and the following theorems obtained. Theorem: Let G be a p-group, not of class two and let $Z(G)$ denote the center of G. If $G/Z(G)$ is a product of elementwise commuting proper subgroups,

then G is an in-direct product. Theorem: Let G be a p-group of class two. G is not an in-direct product if and only if $Z(G)$ is cyclic and G may be generated by two elements.
J. E. Adney (E. Lansing, Mich.)

Thompson, John G. 5911
Fixed points of p-groups acting on p-groups.
Math. Z. **86** (1964), 12–13.

The author proves two theorems. (1) Let p be an odd prime. Let $\mathfrak{B}$ be a p-group such that its Frattini subgroup $D(\mathfrak{B})$ is elementary abelian and central in $\mathfrak{B}$. Let $\mathfrak{A}$ be a p-group of operators acting on $\mathfrak{B}$ such that $V = \mathfrak{B}/D(\mathfrak{B})$ is a free $Z_p(\mathfrak{A})$-module, where $Z_p(\mathfrak{A})$ denotes the group ring of $\mathfrak{A}$ over the field of p elements. Let $C_{\mathfrak{B}}(\mathfrak{A})$ and $C_V(\mathfrak{A})$ be centralizers of $\mathfrak{A}$ in $\mathfrak{B}$ and V, respectively. Then $C_{\mathfrak{B}}(\mathfrak{A})D(\mathfrak{B})/D(\mathfrak{B}) = C_V(\mathfrak{A})$. The proof rests on a theorem of Blackburn on p-groups of maximal class [Acta Math. **100** (1958), 45–92; MR **21** #1349]. (2) Let p be an odd prime. Let $\mathfrak{G}$ be a p-solvable group. Let $\mathfrak{A}$ be a p-subgroup of $\mathfrak{G}$ such that its centralizer in $\mathfrak{G}$ has the form: $C_{\mathfrak{G}}(\mathfrak{A}) = Z(\mathfrak{A}) \times \mathfrak{T}$, where $Z(\mathfrak{A})$ is the center of $\mathfrak{A}$ and $\mathfrak{T}$ has an order prime to p. Let $\mathfrak{K}$ be a subgroup of $\mathfrak{G}$ such that $\mathfrak{K}$ has an order prime to p and the normalizer of $\mathfrak{K}$ contains $\mathfrak{A}$. Then $\mathfrak{K}$ is contained in the largest normal subgroup of $\mathfrak{G}$ which has order prime to p.

Held, Dieter 5912
Closure properties and partial Engel conditions in groups.
Illinois J. Math. **8** (1964), 706–712.

Let $\mathfrak{p}$ be a set of primes and σ a partial ordering of $\mathfrak{p}$ such that $p\sigma p$ is false for every prime p in $\mathfrak{p}$. A σ-segment is a nonempty subset $\mathfrak{s}$ of $\mathfrak{p}$ defined by the following property: If q belongs to $\mathfrak{s}$ and $p\sigma q$, then p belongs to $\mathfrak{s}$, too. The group G is called $\mathfrak{a}$-closed for $\mathfrak{a}$ a set of primes if products of $\mathfrak{a}$-elements of G are $\mathfrak{a}$-elements. A torsion group is called $(\mathfrak{p}, \sigma)$-dispersed if it is $\mathfrak{s}$-closed for every σ-segment $\mathfrak{s}$ of $\mathfrak{p}$. The author investigates sufficient conditions in order that the set of all $\mathfrak{p}$-elements of a torsion group G constitute a $(\mathfrak{p}, \sigma)$-dispersed subgroup of G. One of the conditions given by the author is as follows. (0) Every finitely generated subgroup of G satisfies the maximum and minimum conditions for subgroups. (1) Epimorphic images of subgroups of G are called factors of G. If $p \in \mathfrak{p}$, then p-factors of G are locally finite. (2) If p and q are different primes such that $p \in \mathfrak{p}$ and $q\sigma p$ is false, and if a is a p-element and b a q-element of G, then for almost every positive integer i the order of an iterated commutator $a^{(i)} \circ b$ is divisible by primes r with $r\sigma p$ only. (3) Any infinite factor F of G which can be generated by finitely many $\mathfrak{p}$-elements contains an element of prime order p such that there is no element of F of prime order q with $q\sigma p$.

Kemhadze, Š. S. 5914
Groups generated by nilpotent and ZA-subgroups. (Russian)
Sibirsk. Mat. Ž. **5** (1964), 827–837.

A group is an N-group if every proper subgroup of it is properly contained in its normalizer. The paper starts out with the remark that the N-group G has a non-trivial center provided there is a normal subgroup A in G with non-trivial center and a ZA-group (i.e., the ascending central sequence terminates at the "top" only) B such that $G = AB$. In a similar way the author obtains the following Theorem 5: If A, B are ZA-groups, subnormal in the group G such that $G = AB$, then G is ZA. The corresponding result holds with "locally nilpotent" replacing ZA (Theorem 6).
O. H. Kegel (Frankfurt a.M.)

Kemhadze, Š. S. 5915
The factorization of groups by accessible subgroups. (Russian)
Sibirsk. Mat. Ž. **5** (1964), 838–843.

In the same vein as in the preceding paper [#5914], the author proves that if A and B are permutable nilpotent subnormal subgroups of the group G, then the product AB is a nilpotent subnormal subgroup of G.
O. H. Kegel (Frankfurt a.M.)

Polovickiĭ, Ja. D. 5916
Groups with extremal classes of conjugate elements. (Russian)
Sibirsk. Mat. Ž. **5** (1964), 891–895.

G is a group with extremal classes of conjugate elements if G induces in each class a^G an extremal group of permutations, i.e., if $G/\mathfrak{C}(a^G)$ is a finite extension of a (divisible) commutative group with minimal condition, where $\mathfrak{C}(A)$ denotes the centralizer of A in G. For a discussion of extremal groups cf. R. Baer [Trans. Amer. Math. Soc. **79** (1955), 521–540; MR **17**, 125]. If G has extremal classes, then G' is a torsion group. Theorem: G is a group with extremal classes if and only if (a) each class a^G generates a subgroup which is either extremal or an infinite cyclic extension of an extremal group, and (b) $G/\mathfrak{C}(a^G)$ is a torsion group for each $a \in G$. Corollary. G has finite classes of conjugate elements if and only if each class generates a cyclic extension of a finite group.
H. Salzmann (Frankfurt a.M.)

Maass, Hans 5917
Die Multiplikatorsysteme zur Siegelschen Modulgruppe.
Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. II **1964**, 125–135.

Let Γ_n be the modular group of degree $n > 1$. A multiplier system on Γ_n of integral dimension (the only dimensions of

interest when $n>1$) is a character v of Γ_n of absolute value 1. The author proves that

$$(\Gamma_n:\Gamma_n') = 2, \quad n=2,$$
$$= 1, \quad n>2.$$

Since v is identically 1 on Γ_n', there is a nontrivial multiplier system only for Γ_2. The author characterizes Γ_2' by means of congruences and exhibits the unique character v on Γ_2 by its action on the generators.

In a note added in proof the author remarks that, unknown to him, the results of this paper had already been obtained by I. Reiner [Proc. Amer. Math. Soc. **6** (1955), 987–990; MR **17**, 710]. The reader should note that the author writes Γ_n for the modular group of degree n whereas Reiner writes Γ_{2n}. *J. Lehner* (College Park, Md.)

Götzky, Martin 5918

Eine Kennzeichnung der orthogonalen Gruppen unter den unitären Gruppen.

Arch. Math. **15** (1964), 261–265.

Let K be a sfield of characteristic $\neq 2$, $U_n(K,f)$ a unitary group with $n\geqq 2$. The author gives a proof of a theorem of F. Bachmann giving a condition on $U_n(K,f)$ which implies that K is commutative, and the involution in K is the identity (hence $U_n(K,f)$ is then an orthogonal group). The condition involves symmetries with respect to non-isotropic hyperplanes, and reads as follows: If three hyperplanes H_i are orthogonal to non-isotropic linearly dependent vectors, and s_i is the symmetry with respect to H_i ($i=1,2,3$), then $s_1s_2s_3$ is again a symmetry with respect to a non-isotropic hyperplane.

J. Dieudonné (Paris)

Tsuzuku, Tosiro 5919

A characterization of finite projective linear groups.

Proc. Japan Acad. **40** (1964), 155–156.

Let G be a finite group with a Bruhat decomposition satisfying the axioms of Steinberg [Canad. J. Math. **9** (1957), 347–351; MR **19**, 387]. Suppose the Weyl group is the symmetric group of degree $n\geqq 4$ and that the canonical set of generators is $(1,2),\cdots,(n-1,n)$. The author sketches a proof of the theorem that under these hypotheses G has a homomorphic image isomorphic with $\mathrm{PSL}_n(q)$ or A_7. The proof is made by constructing the appropriate projective space and showing that G has a flag-transitive action on this space. The conclusion then follows from a theorem of D. G. Higman [Illinois J. Math. **6** (1962), 434–446; MR **26** #663]. {Reviewer's note: It is easy to see that the case A_7 cannot, in fact, occur.}

J. McLaughlin (Ann Arbor, Mich.)

Brauer, Richard 5920

Some applications of the theory of blocks of characters of finite groups. I.

J. Algebra **1** (1964), 152–167.

This paper consists primarily of the deduction of some consequences and refinements of the author's main theorems on p-blocks [Math. Z. **63** (1956), 406–444; MR **17**, 824; ibid. **72** (1959/60) 25–46; MR **21** #7258]. There are several results which bound the order of $G/\mathfrak{O}_p'(G)$ in terms of various properties of G. In connection with this the author introduces the concept of "deficiency class", and some results are obtained concerning groups of deficiency class 0. In case $p=2$ analogous results are also obtained about groups of deficiency class 1. The final part of the paper is a discussion of how the main theorem in the second paper mentioned above may be modified if the modular characters in a block of $\mathfrak{C}_G(\pi)$ are replaced by an arbitrary basis of the Z-module spanned by these modular characters. Here π is an arbitrary p-element of G.

W. Feit (New Haven, Conn.)

Conlon, S. B. 5921

Twisted group algebras and their representations.

J. Austral. Math. Soc. **4** (1964), 152–173.

Let G be a finite group and F a field. A twisted group algebra $A(G)$ of G over F is an associative algebra over F with an F-basis $\{u(g)\}$ in one-to-one correspondence with the elements $g\in G$, and such that $u(g)u(g')=f(g,g')u(gg')$, $f(g,g')\in F$, $f(g,g')\neq 0$. The author first shows that, by extending the field F and replacing the $u(g)$ by suitable scalar multiples of themselves, a twisted group algebra can be normalized so that the structure constants $f(g,g')$ are manageable (the precise conditions are too involved to describe here). Let $A(G)$ be a normalized twisted group algebra of G over F, let H be a subgroup of G, and let $A(H)$ be the subalgebra of $A(G)$ determined by H. Let L be a left $A(H)$-module. The induced module L^G is defined to be the left $A(G)$ module $A(G)\otimes_{A(H)}L$. The first main result is a generalization of P. A. Tucker's result on ordinary induced representations [Amer. J. Math. **84** (1962), 400–420; MR **26** #1353]. Let $A(H)$ be the restriction of a normalized twisted group algebra $A(G)$ over an algebraically closed field F to a normal subgroup H of G. Let L be an indecomposable $A(H)$-module, and S the subgroup of G consisting of all $s\in G$ such that $u(s)\otimes L\simeq L$. The theorem states that the decomposition of L^G into indecomposable submodules is entirely determined by the decomposition of a certain twisted group algebra $A(S/H)$ into left ideals, there being a one-to-one correspondence between left ideal components of $A(S/H)$ and components of L^G such that two left ideal components are isomorphic if and only if the corresponding components of L^G are isomorphic. The dimensions over F of the components of L^G are given in terms of the dimensions of the corresponding left ideals.

The author next adapts A. Rosenberg's version [Math. Z. **76** (1961), 209–216; MR **24** #A158] of R. Brauer's main theorem on blocks to the case of twisted group algebras. Rather complete generalizations are also given, for twisted group algebras, of D. G. Higman's theory of relatively projective modules over group algebras [Duke Math. J. **21** (1954), 377–381; MR **16**, 794] and J. A. Green's work on the vertex and source of an indecomposable module [Math. Z. **70** (1958/59), 430–445; MR **24** #A1304].

C. W. Curtis (Eugene, Ore.)

Fischer, Bernd 5922

Die Brauersche Charakterisierung der Charaktere endlicher Gruppen.

Math. Ann. **149** (1962/63), 226–231.

Let G be a finite group and $C(G)$ its character ring. If U is a subgroup of G and φ an element of $C(U)$, then φ^G denotes

the induced generalized character of G. For a set of subgroups $\mathfrak{M}$ of G let $V(\mathfrak{M})$ be the set of functions $\sum_{U \in \mathfrak{M}} a_U \varphi_U{}^G$, where a_U is an integer and φ_U is an element of $C(U)$. Finally, let $U(\mathfrak{M})$ denote the complex-valued class functions on G whose restriction to a subgroup W of $\mathfrak{M}$ is an element of $C(W)$. Brauer and Tate [Ann. of Math. (2) **62** (1955), 1–7; MR **16**, 1087] showed $V(\mathfrak{M})$ is an ideal of the ring $U(\mathfrak{M})$ and $U(\mathfrak{M}) \supseteq C(G) \supseteq V(\mathfrak{M})$. The main theorem of this paper is that the following properties of a set of subgroups $\mathfrak{M}$ of a finite group G are equivalent: (a) $U(\mathfrak{M}) = C(G)$; (b) $V(\mathfrak{M}) = C(G)$; (c) If E is an elementary nilpotent subgroup of G, then there is a subgroup of G contained in a member of $\mathfrak{M}$ and conjugate to E. (A finite group is called elementary nilpotent if it is the direct product of a cyclic group and a p-group.)

Reiner, Irving 5923

On the number of irreducible modular representations of a finite group.

Proc. Amer. Math. Soc. **15** (1964), 810–812.

Let K be a field of characteristic p, and G a finite group. Let n be the L.C.M. of the orders of the p-regular elements of G, and let δ be a primitive nth root of 1 over K. Each K-automorphism of $K(\delta)$ is given by a mapping $\delta \to \delta^t$ for some integer t representing a unit in $Z/(n)$. The multiplicative group T of $Z/(n)$ is isomorphic to the Galois group of $K(\delta)$ over K. Two p-regular elements $a, b \in G$ are called K-conjugate if $b^t = x^{-1}ax$ for some $x \in G$ and $t \in T$. Berman proved [Dokl. Akad. Nauk SSSR **106** (1956), 767–769; MR **17**, 1181] that the number of irreducible K-representations of G equals the number of p-regular K-conjugacy classes of G. The author gives a new proof of Berman's theorem using the theory of Brauer characters of G [see C. W. Curtis and I. Reiner, *Representation theory of finite groups and associative algebras*, Chapter XII, Interscience, New York, 1962; MR **26** #2519].

Srinivasan, Bhama 5924

The modular representation ring of a cyclic p-group.

Proc. London Math. Soc. (3) **14** (1964), 677–688.

Let G be a cyclic group of order p^a, and let K be a field of characteristic p, for some prime p. The set of all isomorphism classes of finitely generated KG-modules forms a commutative ring R with operations $\{M\} + \{M'\} = \{M \oplus M'\}$, $\{M\} \cdot \{M'\} = \{M \otimes M'\}$. The ring R is a free Z-module with a basis consisting of the p^a distinct isomorphism classes $\{M_i\}$, $i = (M_i : K)$, $1 \leq i \leq p^a$, of indecomposable ZG-modules. For each pair of basis elements $\{M_n\}$ and $\{M_m\}$, there exist integers a_{nml} such that $\{M_n\}\{M_m\} = \sum_l a_{nml}\{M_l\}$. The author determines the integers a_{nml} explicitly. In case $n + m - 1 < p$, the formula reduces to $\{M_n\}\{M_m\} = \sum_{j=1}^{n} \{M_{n+m-2j+1}\}$, which agrees with a classical formula for tensor products of cyclic nilpotent matrices at characteristic zero [D. E. Littlewood, *The theory of group characters and matrix representations of groups*, p. 196, Oxford Univ. Press, New York, 1940; MR **2**, 3]. J. A. Green proved that if C is the complex field, then $R \otimes_Z C$ is a semi-simple algebra, without actually calculating the integers a_{nml} [Illinois J. Math. **6** (1962), 607–619; MR **26** #5106].

Note on a paper of Tsuzuku.

Proc. Glasgow Math. Assoc. **6**, 196–197 (1964).

The author corrects an argument used by T. Tsuzuku [Nagoya Math. J. **22** (1963), 79–82; MR **27** #4853] in proving the following theorem. Let G be a doubly transitive permutation group of degree n and ρ its representation by $n \times n$ permutation matrices. If K is any commutative ring with unity, then ρ is decomposable over K if and only if n is an invertible element of K.

G. de B. Robinson (Toronto, Ont.)

Levine, Jack; Korfhage, Robert R. 5926

Automorphisms of abelian groups induced by involutory matrices, general modulus.

Duke Math. J. **31** (1964), 631–653.

Let Z_q denote the ring of rational integers modulo q, and let n be a fixed positive integer. The authors study the collection of all $n \times n$ matrices X with entries in Z_q, satisfying $X^2 = I$, the identity matrix. It is convenient to view such involutory matrices as representing involutions on the additive group G which is the direct sum of n copies of Z_q.

Hereafter, let $q = 2^m$, $m > 1$, which is the case of main interest in the present paper. (Previous articles by various authors have dealt with the cases where $m = 1$, or where q is a power of an odd prime.) Given an involution μ on G, its fixed group F is defined by $F = \{x \in G : \mu(x) = x\}$. The authors show easily that the additive structure of F cannot be arbitrary, but rather there exist non-negative integers α, β and γ such that F is a direct sum of α copies of Z_2, β copies of $Z_{2^{m-1}}$, and γ copies of Z_{2^m}. We shall say that such a direct sum has type $\langle \alpha, \beta, \gamma \rangle$. Conversely, the more difficult result is established: Given non-negative integers α, β and γ such that

$$(*) \qquad n - 2\gamma \leq \alpha + \beta \leq n - \gamma,$$

there exist involutions on G whose fixed group has type $\langle \alpha, \beta, \gamma \rangle$.

Fix some canonical basis for G; then each involutory matrix X defines an involution μ on G, and hence also defines a fixed group F. It is not hard to show that the number of involutory matrices X with a given fixed group F_0 of type $\langle \alpha, \beta, \gamma \rangle$ depends only upon α, β and γ, rather than upon the group F_0. Let F_0 be a subgroup of G of type $\langle \alpha, \beta, \gamma \rangle$, chosen in some canonical way. Let $r(\alpha, \beta, \gamma)$ be the number of involutory matrices X with fixed group F_0, and let $s(\alpha, \beta, \gamma)$ be the number of subgroups of G of type $\langle \alpha, \beta, \gamma \rangle$. Then the total number $N(q, n)$ of involutory $n \times n$ matrices with entries in Z_q is given by

$$N(q, n) = \sum r(\alpha, \beta, \gamma) s(\alpha, \beta, \gamma),$$

where the summation extends over all triples (α, β, γ) of non-negative integers satisfying (*).

The factor $s(\alpha, \beta, \gamma)$ can be computed directly from the Yeh-Delsarte formula. The determination of $r(\alpha, \beta, \gamma)$ is more difficult, and depends upon exhibiting all involutory matrices X which fix F_0, and then deciding which of these have F_0 as fixed group. The authors eventually obtain an explicit formula for $N(q, n)$.

The same methods yield a formula for $N(p^a, n)$, where p is an odd prime. The arguments are considerably simpler in this case, however. Since $N(\prod p_i^{a_i}, n) = \prod N(p_i^{a_i}, n)$, the authors are thus able to evaluate $N(t, n)$ for each positive integer t.

Cilang, H. [Zieschang, H.] 5927

On automorphisms of plane groups. (Russian)

Dokl. Akad. Nauk SSSR **155** (1964), 57–60.

Let G be a plane group with a compact fundamental region R, and let N be the closed orientable surface obtained by identifying equivalent boundary points of R. An autohomeomorphism of N is called admissible if it maps every branch point onto a branch point of the same order. G admits the following presentation:

$$G = \langle p_1, \cdots, p_m, a_1, b_1, \cdots, a_g, b_g;$$

$$p_1^{k_1} = 1, \cdots, p_m^{k_m} = 1, \prod_{j=1}^{m} p_j \cdot \prod_{i=1}^{g} a_i b_i a_i^{-1} b_i^{-1} = 1 \rangle.$$

Let $F = \langle p_1, \cdots, p_m, a_1, b_1, \cdots, a_g, b_g \rangle$. Theorem 1: Every automorphism of G is induced by an automorphism α of F satisfying the following equations:

$$\alpha(p_i) = T_i p_{n_i} T_i^{-1}, \qquad i = 1, \cdots, m,$$

$$\alpha\left(\prod_{j=1}^{m} p_j \cdot \prod_{i=1}^{g} a_i b_i a_i^{-1} b_i^{-1}\right) = T \cdot \prod_{j=1}^{m} p_j \prod_{i=1}^{g} a_i b_i a_i^{-1} b_i^{-1} \cdot T^{-1},$$

where $\begin{pmatrix} 1 \cdots m \\ n_1 \cdots n_m \end{pmatrix}$ is a permutation with $K_{n_i} = K_i$ and $T_1, \cdots, T_m, T$ are arbitrary words in F.

The author sketches a proof of the equivalence of the group-theoretical Theorem 1 and the following generalization of Nielsen's theorem (Theorem 2): Every automorphism of G is induced by an admissible autohomeomorphism of N. *M. Greendlinger* (Ivanovo)

Fried, E. 5928

On the subgroups of an Abelian group that are ideals in every ring.

Proc. Colloq. Abelian Groups (*Tihany*, 1963) *pp.* 51–55. *Akadémiai Kiadó, Budapest*, 1964.

A ring over a given (abelian) group G is a ring with additive group isomorphic to G. The author obtains characterizations for the subgroups of an arbitrary group G which are ideals in every ring over G. Let $\mathfrak{J}(G)$ be that ideal of the endomorphism ring $\mathfrak{E}(G)$ of G which is generated by all homomorphic images of G into the additive group of $\mathfrak{E}(G)$. Subgroups H^* and $\bar{H}$ of G corresponding to the subgroup H are defined thus: H^* is generated by all g such that $g\varphi \in H$ whenever $\varphi \in \mathfrak{J}(G)$, and $\bar{H}$ is generated by all $h\varphi$ with $h \in H$ and $\varphi \in \mathfrak{J}(G)$. Then Theorem 2 states that each of the following four conditions is necessary and sufficient for H to be an ideal in every ring over G: (1) $\bar{H} \subseteq H$, (2) there exists a fully invariant subgroup T of G such that $\bar{T} \subseteq H \subseteq T^*$, (3) there exists a fully invariant subgroup S of G such that $\bar{S} \subseteq H \subseteq S$, (4) $H \subseteq H^*$. The proofs are elementary. The author also considers groups G in which only the fully invariant subgroups are ideals in all rings over G. Finally, two problems are posed. *I. D. Macdonald* (Newcastle, N.S.W.)

Leptin, H. 5929

Einige Bemerkungen über die Automorphismen Abelscher p-Gruppen.

Proc. Colloq. Abelian Groups (*Tihany*, 1963), *pp.* 99–104. *Akadémiai Kiadó, Budapest*, 1964.

Let G be a reduced Abelian p-group, and let S be the socle of G. For every ordinal μ, put $S^\mu = S \cap (p^\mu G)$. Then any endomorphism η of G induces in the factor group $S^\mu/S^{\mu+1}$ an endomorphism η_μ. H. Freedman [Proc. London Math. Soc. (3) **12** (1962), 77–99; MR **24** #A2215] proved the following theorem. Let $p \geq 5$, and let G be of finite Ulm type, i.e., $p^{n\omega}G = 0$ for a natural number n. If an automorphism α of G satisfies $\alpha_\mu = 1$ for every μ and $\alpha^p = 1$, then $\alpha = 1$ on pG.

In the present paper, the author shows that the assumption of finiteness of Ulm type is superfluous by proving the following theorem. Let $p \geq 5$, and let G be a reduced p-group. If an automorphism α of G satisfies $\alpha_\mu = 1$ for every $\mu < \omega$, then $\alpha = 1$ on pG if and only if $\alpha^p = 1$. *K. Honda* (Tokyo)

Banaschewski, B. 5930

On lattice-ordered groups.

Fund. Math. **55** (1964), 113–122.

Lorenzen [Math. Z. **45** (1939), 533–553; MR **1**, 101] has shown that a lattice-ordered Abelian group has a realization as a subgroup of a direct product of totally ordered groups, and Ribenboim [Pacific J. Math. **10** (1960), 305–308; MR **22** #1624] has shown that this realization can be made completely regular. The problem in the case of a general lattice-ordered group G is approached here by studying the epimorphisms of G to totally ordered groups by using the concept of a zero-dimensional subgroup of a product of totally ordered groups. A full subgroup H of $\prod T_\alpha$, $\alpha \in I$, is zero-dimensional if, in the topology on I defined by the basis $s(u) = \{\alpha \mid u(\alpha) \neq 0\}$, $u \in H$, of open sets, the sets $s(u)$ are also closed. (Zero-dimensionality can be shown to be equivalent to complete regularity.) Various results concerning these concepts are expressed in terms of properties of the prime filters in the lattice P of positive elements of G, and these are used to prove the equivalence of the following statements: (i) G has a zero-dimensional realization, (ii) G has a realization, (iii) no strictly positive element of G is disjoint from any of its conjugates, (iv) each ultrafilter in P is normal.

The author compares his method of proof with that of Ribenboim and is able to generalize another of the latter's results concerning the lattice of filets of P. Some further results are found in the special case of a complete lattice-ordered group. *J. C. Ault* (Leicester)

Ciampa, Salvatore 5931

Osservazioni sull'ordinabilità dei gruppi.

Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 111–136.

Let G be a group with identity e. For $H \subseteq G$, let H^+ be the subsemigroup generated by H. Let $H^{-1} = \{x^{-1} : x \in H\}$, and $H^* = \bigcap \{[K \cup (H - K)^{-1}]^+ : K \subseteq H\}$. Call H weakly stable (w.s.) if $H^* \subseteq H$. The author obtains a number of properties of H^*. For example, $H^* = \bigcup \{F^* : F \subseteq H, F$ finite$\}$. If $H \cap H^* = \varnothing$, then $H^* = \varnothing$. If $e \notin H$ and H is w.s., then every subset of H is w.s. If $e \notin H^*$, H is w.s.

These results are applied to obtain several equivalent conditions for G to be right orderable (i.e., for the existence of a total order $\leq$ on G for which $a \leq b$ always implies $ac \leq bc$). For example, G is right orderable if and only if G^0 $(= \{x \in G : x \neq e\})$ is w.s., or equivalently if and only if $H^* = \{e\}$ whenever $H \neq \varnothing$ is finite. As the author points out, some of these conditions were found by Conrad [Michigan Math. J. **6** (1959), 267–275; MR **21** #5684], and another is

somewhat similar to a result of the reviewer [Proc. Amer. Math. Soc. 13 (1962), 217–219; MR 24 #A3216]. Corollary: A simple group G is right orderable if and only if, for some $H \subseteq G$, $H \cup H^{-1} = G^0$ and $H^+ \neq G$.

In the last section, the extendibility (to a right total order) of a right partial order is discussed. An example is given of a right orderable group having a right partial order which is not extendible. Theorem: A given right partial order is extendible if the set of elements not comparable with e is the union of two subsemigroups. This leads to some sufficient conditions for the extendibility of every right partial order. *E. J. Tully, Jr.* (Davis, Calif.)

Curzio, Mario 5932

Elementi $\bigcup$-quasi-distributivi in alcuni reticoli di gruppi.

Ricerche Mat. **13** (1964), 70–79.

Secondo una definizione dello stesso autore [stessi Ricerche **6** (1957), 96–110; MR **20** #905] un elemento a di un reticolo $\mathscr{R}$ si dice $\cup$-quasi distributivo ($\cup$-q.d.) in $\mathscr{R}$ se

$$x, y \in \mathscr{R}: x \cup a = y \cup a \Rightarrow x \cup a = (x \cap y) \cup a.$$

In questa nota si caratterizzano gli elementi $\cup$-q.d. del reticolo $\mathscr{L}(G)$ dei sottogruppi di un gruppo G finito o abeliano, dimostrando che, se G è un tale gruppo, $A \in \mathscr{L}(G)$ è $\cup$-q.d. se e solo se l'applicazione

$$X \in \mathscr{L}(G) \to A \cup X$$

è un endomorfismo di $\mathscr{L}(G)$ e riconducendone la determinazione a noti risultati di Higman, Sato e Zappa.

Si prova inoltre che se G è un gruppo qualunque (un gruppo finito risolubile) la classe degli elementi $\cup$-q.d. nel reticolo dei sottogruppi normali di G (nel reticolo dei sottogruppi di composizione di G) coincide con quella degli elementi neutri. *L. A. Rosati* (Firenze)

Dubreil-Jacotin, Marie-Louise 5933

Sur les images homomorphes d'un demi-groupe ordonné.

Bull. Soc. Math. France **92** (1964), 101–115.

The author investigates o-homomorphic images of partially ordered semigroups. The results are similar to, but more general and more extended than, recent results of L. Fuchs [Acta Sci. Math. (Szeged) **25** (1964), 139–142; MR **29** #3554]. Among other results, the author proves the following (we use notation defined in the review cited above). If S is a partially ordered semigroup containing an element e such that for each $a \in S$, $\langle e^{\cdot} . a\rangle = \langle e. {}^{\cdot}a\rangle$, and $\langle e^{\cdot} . e\rangle = \{x \in S \mid x \geq e\}$, then there exists a unique o-homomorphism β of S onto a partially ordered semigroup $\bar{S}$ with neutral element $e\beta$, such that $a\beta \leq e\beta$ implies $a \leq e$. Then $a\beta = b\beta$ if and only if $\langle e^{\cdot} . a\rangle = \langle e^{\cdot} . b\rangle$ if and only if $\langle e. {}^{\cdot}a\rangle = \langle e. {}^{\cdot}b\rangle$. $\bar{S}$ is a group if and only if each $\langle e^{\cdot} . a\rangle$ has left multiplicatively maximal elements. The theory is applied to the study of certain subsemigroups of the semigroup of subsets of a semigroup.

Kopytov, V. M. 5934

On the completion of the center of an ordered group. (Russian)

Ural. Gos. Univ. Mat. Zap. **4**, *tetrad* **3**, 20–24 (1963).

It is shown that every fully ordered group G with center $Z(G)$ can be embedded in a fully ordered group G^* with divisible center $Z(G^*)$ such that $Z(G) \subseteq Z(G^*)$ and the factor groups $G/Z(G)$ and $G^*/Z(G^*)$ are isomorphic abstract groups. If G as an abstract group has the property that every partial order can be extended to a full order of G, then G^* has the same property. Corollaries: (1) A torsion-free group can be fully ordered if and only if the factor group modulo its center can be fully ordered; (2) If a group can be fully ordered, then it admits a full order in which the center is a convex subgroup.

Principal components and prime factorization in partially ordered semigroups.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 103–111.

Two new sets of conditions are obtained for unique prime factorisation in a partially ordered semigroup (not necessarily commutative), generalising the fundamental theorem or commutative ideal theory. The concept of principal component is introduced and its properties are studied. Let S be a partially ordered semigroup with more than one element satisfying the conditions: (i) S is negatively ordered and has a maximum element e which is a left identity; (ii) Every pair of elements a, b of S have a least upper bound $a \vee b$; (iii) If $a \neq 0$, the set of elements x in S with $a \leqq x \leqq e$ satisfies the minimum condition; (iv) For every $a, b \in S$, there exist right and left residuals $a \cdot b$ and $a::b$, such that $xb \leqq a$ if and only if $x \leqq a \cdot b$, and $bx \leqq a$ if and only if $x \leqq a::b$. Then, if p is a prime in S and $0 < a < e$, there exists a unique element $a(p) \in S$, called the right principal component of a belonging to p, such that $a : y \nleqq p$ if and only if $y \leqq a(p)$, and there exist a finite number of primes $p_1, \cdots, p_r \in S$ such that $a = a(p_1) \wedge \cdots \wedge a(p_r)$. If, further, S also satisfies the conditions: (v) If $a \neq 0$, then $ba = a$ implies $b = e$ and $ba = 0$ implies $b = 0$, (vi) If p is a prime, $a < b \leqq p$ implies $a : p < b : p$; then the above principal components of a are commuting prime powers, so that $a = p_1^{k_1} \cdots p_r^{k_r}$. Finally, if S satisfies conditions (i) and (v) and the further conditions: (III) $a < b$ implies $a = bc$ for some $c \in S$, (IV) S satisfies the maximum condition; (V) The right residual $a : b$ exists for all $a, b \in S$; then e is the identity of S and every element $a \in S$, $0 < a < e$, can be represented uniquely as the product of pairwise commuting primes.

Hedrlín, Z.; Pultr, A. 5942

Relations (graphs) with given finitely generated semigroups.

Monatsh. Math. **68** (1964), 213–217.

Let $S(\cdot)$ be a semigroup with unity element, and $A \subset S$ a set of generators of $S(\cdot)$. Then there exists a system of binary relations R_a over S, with one relation for each a in A, such that the set of all transformations compatible with the relations R_a forms, under composition, a semigroup isomorphic with $S(\cdot)$. Using this theorem, the authors then obtain the following graph-theoretic result. For each finitely generated semigroup $S(\cdot)$ with unity element there exist infinitely many non-isomorphic graphs G such that $S(\cdot)$ is isomorphic with the semigroup of all endomorphisms of G. The proofs use a construction similar to that used by R. Frucht [Compositio Math. **6** (1938), 239–250].

A class of groupoids: Tribes. Embedding in a tribe. (Spanish)

Collect. Math. **15** (1963), 153–167.

Let H be the union of a non-empty family $\{G_i \mid i \in I\}$ of disjoint groups, and for every $i \in I$ let σ_i be an isomorphism of G_i onto a group G. For every $a \in G_i$ and $b \in G_j$ there exists a single $c \in G_j$ such that $\sigma_i(a)\sigma_j(b) = \sigma_j(c)$. H is a semigroup under the operation $ab = c$. Such semigroups are called tribes. The author finds various properties of tribes. If S is a left-cancellable semigroup satisfying the properties: that $ac = bc$ implies $ad = bd$ for every a, b, c, $d \in S$ and that for every $a, b, c \in S$ there exist $x, y \in S$ such that $xac = ybc$, then S can be imbedded in a tribe.

To all appearances the author is not aware that his tribes are exactly the right groups whose properties have been repeatedly rediscovered by many authors since 1928 [cf. A. H. Clifford and G. B. Preston, *The algebraic theory of semigroups*, Vol. I, Amer. Math. Soc., Providence, R.I., 1961; MR **24** #A2627].

Semigroups all of whose subsemigroups coincide with their own idealizers. (Russian)

Ural. Gos. Univ. Mat. Zap. **3**, *tetrad* 1, 85–87 (1961).

The [left] idealizer of a subsemigroup H of a semigroup Γ is the greatest subsemigroup of Γ in which H is a [left] ideal. It is shown that Γ has the property that each of its subsemigroups coincides with its [left] idealizer if and only if Γ is the set-theoretic union of pairwise disjoint groups and another simple condition is satisfied.

L. Fuchs (Budapest)

Šutov, È. G. 5945

Embedding of semigroups into simple semigroups with one-sided division. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 5 (42), 143–148.

Let S be an infinite set and q an equivalence on S with infinitely many equivalence classes; for any transformation α of S (into itself) denote by S_α^* the set of all q-classes not meeting αS. Further, denote by Σ_S^* the set of transformations α such that, for any $a, b \in S$, (i) $a \equiv b\ (q)$ implies $\alpha a = \alpha b$, (ii) $\alpha a \equiv \alpha b\ (q)$ implies $a \equiv b\ (q)$, (iii) S_α^* is equipotent to the set S_q of all q-classes. Then Σ_S^* is a subsemigroup of the semigroup Σ_S of all transformations of S, with right division and no idempotents; moreover, the semigroups Σ_S^* generate the universal class of semigroups with this property. Given $\alpha, \beta \in \Sigma_S^*$, write $\omega(\alpha, \beta)$ for the cardinal of the set of q-classes M such that $\alpha M \neq \beta M$, and for any infinite cardinal λ, denote by $\sigma[\lambda]$ the relation on Σ_S^* for which $\alpha \equiv \beta\ (\sigma[\lambda])$ if and only if $\omega(\alpha, \beta) < \lambda$. The author proves that each $\sigma[\lambda]$ is a congruence on Σ_S^* and these are all the congruences. Taking λ_0 to be the cardinal of S_q one thus finds the quotient semigroup $\Sigma_S^*/\sigma[\lambda_0]$ to be simple (i.e., without proper quotients). As a consequence the author shows that a semigroup B without idempotents can be embedded in a simple semigroup with right divisibility if and only if for all $a, b, x, y \in B$, $ax = ay$ implies $bx = by$. This is used to give a simple proof of a result by the reviewer [J. London Math. Soc. **31** (1956), 169–181; MR **18**, 14].

P. M. Cohn (Chicago, Ill.)

Šutov, È. G. 5946

Translations of semigroups. (Russian)

Uspehi Mat. Nauk **19** (1964), no. 4 (118), 215–218.

Let S be a semigroup. Let $F(S)$, $F_1(S)$, $\Phi(S)$, $\Phi_1(S)$ mean, respectively, the semigroups of all left, inner left, right, inner right translations of S [T. Tamura, Kōdai Math. Sem. Rep. 7 (1955), 67–70; MR **18**, 318].

The author shows that any semigroup A is isomorphic to some $F_1(B)$ with $B \supset A$. He proves also that for any A the following conditions are equivalent: (1) $F(A) = F_1(A)$ and $\Phi(A) = \Phi_1(A)$; (2) there exists a two-sided ideal densely imbedded in A [L. M. Gluskin, Mat. Sb. (N.S.) **55** (**97**) (1961), 421–448; MR **25** #3106]; (3) there exists a one-sided ideal densely imbedded in A; (4) A is isomorphic to some $F(B)$; (5) A contains a unity element.

Švarc, V. Ja.; Jaroker, I. S. 5947

Extension elements of semigroups with one-sided unity elements. (Russian)

Uspehi Mat. Nauk **19** (1964), no. 4 (118), 209–214.

The authors construct a semigroup C with two generators u, v and a right unity element $e = vu$ with the following property. Let A be any semigroup with a right unity element $f \in A$. Then $x \in A$ is a right extension element of A (i.e., $A'x = A$ holds for some proper subset $A' \subset A$) if and only if there exists a homomorphism ψ of C into A with $\psi e = f$ and $\psi u = x$. In this case x generates an infinite subsemigroup in A. All homomorphic images of C are found and, among them, all which contain some right extension element. Those with some left extension element are also determined.

The authors' results generalize the investigations of E. S. Ljapin on extension elements in semigroups with a two-sided unity element [*Semigroups* (Russian), Fizmatgiz, Moscow, 1960; MR **22** #11054] and of L. M. Gluskin [Mat. Sb. (N.S.) **41** (**83**) (1957), 23–36; MR **19**, 836].

Halbgruppen ohne Frattinische Unterhalbgruppe.

Acta Math. Acad. Sci. Hungar. **15** (1964), 309–323.

Let S be a semigroup. A totally ordered decomposition $D = \{X, Y, \cdots\}$ of S is called a chain of subsemigroups in S if $XY \subset Y$ and $YX \subset Y$ whenever $X \leq Y$. Call the chain D trivial if $X < Y$ implies $xy = yx = y$ for all $x \in X$, $y \in Y$. Let $\mathbf{C}$ be the class of all S whose Frattini subsemigroup is empty [see, e.g., S. Lajos, Mat. Lapok **10** (1959), 274–277; MR **24** #A1331]. The main results are the following. If D is a trivial chain in S, then $S \in \mathbf{C}$ if and only if $D \subset \mathbf{C}$. For any band $S \in \mathbf{C}$ there is a chain D in S such that all $X \in D$ are rectangular. A general structure theorem describes all such chains. For any semigroup S the assertion $S \in \mathbf{C}$ is equivalent to the existence of a chain in S of a special kind. Among such special chains, if $S \in \mathbf{C}$, a finest one can be found; it consists of all maximal simple subsemigroups. Further results are obtained under the assumption that S admits relative inverses. $S \in \mathbf{C}$ is true for any direct product $S = G \times L$ of a group G and a rectangular band L with $|L| > 1$. The author's results yield many examples of non-splitting semigroups $S \in \mathbf{C}$. All such $S \in \mathbf{C}$ with $|S| = 4$ are determined.

Aus Verfassers Einleitung: "In der vorliegenden Arbeit sollen daher die Grundlagen für eine Theorie der Kategorien mit Nullabbildungen geschaffen werden. Dabei spielt die Feststellung eine wesentliche Rolle, daß das System $^-\Omega$ der Nullabbildungen einer solchen Kategorie ^-K zusammen mit dem Nullelement 0 ein Ideal der $^+$Kategorie $K = {}^-K \cup \{0\}$ bildet, die ... eine Halbgruppe mit Null ist und als $^+$Kategorie mit Nullabbildungen bezeichnet werden soll. Das Ideal $\Omega = {}^-\Omega \cup \{0\}$ ist die Vereinigung aller minimalen (von 0 verschiedenen) ein- und zweiseitigen Ideale von K.... Mittels des halbgruppentheoretischen Nilradikals der Differenzhalbgruppe K/Ω von K mod Ω (die im allgemeinen keine $^+$Kategorie darstellt) läßt sich ein neues Radikal, das 'Ω-Nilradikal' von K bilden.

"Die in Teil IV bemerkte Tatsache, daß sich das Radikal einer beliebigen $^+$Kategorie K abspalten läßt, hat uns dazu veranlaßt, allgemeiner diejenigen Ideale $\mathfrak{a}$ von K zu betrachten, die eine Zerfällung $K = A \cup \mathfrak{a}$, $A \cap \mathfrak{a} = \Omega$, herstellen, wo A eine Teilstruktur von K ist. Solche Ideale nennen wir Ω-isoliert in K". Die Differenzhalbgruppe $K/\mathfrak{a}$ nach einem Ω-isolierten Ideal $\mathfrak{a}$ im allgemeinen keine $^+$Kategorie mehr ist. "Aus diesem Grund führen wir die '$\cap$-Differenz-$^+$Kategorie' $K/_{\kappa}\mathfrak{a}$ ein. Sie stellt für jedes Ideal $\mathfrak{a}$ eine $^+$Kategorie dar, die auch wieder Nullabbildungen besitzt, sobald das für K zutrifft, und die gerade die gewünschte Eigenschaft hat, daß $K_{\mathfrak{a}} = K/_{\kappa}\mathfrak{a} \simeq A$ wird. Damit läßt sich ein Satz über die Abspaltung des Ω-isolierten Bestandteils des Ω-Nilradikals einer $^+$Kategorie mit Nullabbildungen formulieren..., welcher dem Satz über die Abspaltung des Radikals völlig analog ist."

Heimberg, Gilbert 5954

Über eine Zerlegung des Haarschen Masses auf kompakten Gruppen.

Monatsh. Math. **68** (1964), 218–223.

Let X_1 be a compact group and X_2 and X_3 closed subgroups of X_1. Let μ_j denote normalized Haar measure on X_j. The following assertions are equivalent: (1) $\mu_1 = \mu_2 * \mu_3$; (2) $\mu_1 = \mu_3 * \mu_2$; (3) $\mu_2 * \mu_3 = \mu_3 * \mu_2$ and $X_2X_3 = X_1$. Nine other equivalent properties are listed as well, and the case in which X_2 and X_3 are monothetic is dealt with separately. See also the author's earlier communication [same Monatsh. **66** (1962), 417–423; MR **27** #1530].

Edwin Hewitt (Seattle, Wash.)

Rohlin, V. A. 5955

Metric properties of endomorphisms of compact commutative groups. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 867–874.

Let G be a compact commutative group with a countable basis. Let μ be the Haar measure in G. The endomorphisms of G onto G preserve μ and hence are measurable transformations of G with an invariant measure μ. The author proves that every ergodic endomorphism of G onto G has a completely positive entropy [M. S. Pinsker, Dokl. Akad. Nauk SSSR **133** (1960), 1025–1026; MR **27** #2603].

As corollaries one can obtain several previously known theorems concerning the spectrum and mixing properties of such endomorphisms [cf., e.g., P. R. Halmos, Bull. Amer. Math. Soc. **49** (1943), 619–624; MR **5**, 40; V. A. Rohlin, Izv. Akad. Nauk SSSR Ser. Mat. **13** (1949), 329–340; MR **11**, 40].

In particular, the above theorem includes the author's theorem on the positivity of an ergodic automorphism of G onto G [Teor. Verojatnost. i Primenen. **6** (1961), 351–352; MR **27** #2605]. This theorem also implies that every ergodic automorphism of G onto G is a K-automorphism. This fact has been known previously only for some special cases.

Correction to "Compact groups in E^n".

Ann. of Math. (2) **81** (1965), 194.

The authors modify the proofs of the main theorems of an earlier paper [same Ann. (2) **80** (1964), 94–103; MR **29** #189]; the reviewer of the earlier paper indicated how Proposition 3 might be modified so as to be applicable to the proof of Theorem B, but the authors give an alternative method.

Antoine, J.-P.; Speiser, D. 5957a

Characters of irreducible representations of the simple groups. I. General theory.

J. Mathematical Phys. **5** (1964), 1226–1234.

Antoine, J.-P.; Speiser, D. 5957b

Characters of irreducible representations of the simple groups. II. Application to classical groups.

J. Mathematical Phys. **5** (1964), 1560–1572.

The authors present a geometrical version of the character formula for a compact simple Lie group G, which they obtain by geometrically carrying out the division in Weyl's character formula. In detail, let $\beta_1, \cdots, \beta_m$ be the simple negative roots of G, of which the first l are simple, let R_0 be half the sum of the positive roots, and let D_0 be the Weyl chamber containing R_0. Let $\mathscr{G}$ be the lattice $(2\pi Z)^l$ in E_l (corresponding to the center of G in the Stiefel diagram setting in which the authors work). For each $P, \varphi \in E_l$ let $[P] = [P](\varphi) = \exp i(P, \varphi)$. Then for each $K_0 \in \mathscr{G} \cap D_0$ there is an irreducible representation of G whose character χ is given by (Weyl's formula) $\chi = X/\Delta$, where $X = \sum \operatorname{sgn}[sK_0]$, $\Delta = \sum \operatorname{sgn}[sR_0]$, and the sum is over all s in the Weyl group of G. Δ can be written as $\Delta = [R_0] \prod_1^m (1 - [\beta_i])$, and by inverting formally (which the authors show can be justified after multiplication by X), one has $\Delta^{-1} = [-R_0] \sum_k [\sum_1^m k_i\beta_i]$, where the first sum is over all m-tuples $k = (k_1, \cdots, k_m)$ of positive integers. Assuming for the moment that the m roots β_i are linearly independent and thus span E_m, the authors regard the sum as defining all points with positive integral coordinates in the lattice spanned by the β_i, with each point being assigned a multiplicity $+1$. Δ^{-1} is then the same lattice translated by $-R_0$. When one takes into account the relations between the roots, the previous figure is projected onto points in a pyramid in E_l with l surfaces and vertex at $-R_0$. The points $\sum k_i\beta_i$ which occurred with multiplicity $+1$ in E_m correspond to points in the pyramid with multiplicity greater than one in general, and in fact the multiplicity of the point ω is

$P(-w)$, where P is the partition function introduced by Kostant [Trans. Amer. Math. Soc. 93 (1959), 53–73; MR 22 #80]. The final formula for χ is then

$$\chi = \sum_k \left(\sum_s \operatorname{sgs}\left[\sum_1^m k_i\beta_i + sK_0 - R_0 \right] \right),$$

which the authors show is, in fact, a finite sum.

In Part II the authors explicate this formula in detail for the four main classes of simple groups, and for G_2, and in even greater detail for groups of ranks 1 and 2 and for A_3. They also remark that the representations of each of these groups fall into classes which form a group isomorphic to the center of the group.

Maurin, K.; Maurin, L. 5958

Enveloping algebra of a locally compact group and its selfadjoint representations.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **11** (1963), 525–529.

From the introduction: "Let G be a connected separable locally compact group. Using the fact that such a G is a projective limit of Lie groups, the authors define an algebra $E(G)$ with involution which is a natural generalization of the universal enveloping algebra of a Lie group. Next they construct a generalization of the Gårding subspace of H for each unitary representation (U, H) of G, using the space $D(G)$ of 'generalized C^∞ functions with compact support' defined earlier [same Bull. 7 (1959), 471–479; MR 22 #4960]. Using an ingenious idea of Nelson and Stinespring [Amer. J. Math. 81 (1959), 547–560; MR 22 #907], they show that, among others, the representants $dU(M)$ of central symmetric elements $M^* = M \in E(G)$ are essentially self-adjoint and that their closures have commuting spectral resolutions and commute with U. The construction of a 'Gelfand triplet' $\Psi \subset H \subset \Psi'$ (Ψ being nuclear) adapted to the representation (U, H) then allows them to decompose (U, H) as a direct integral of representations $(U(\lambda), H(\lambda))$, and to interpret the spaces $H(\lambda)$ as common eigenspaces of the operators $dU(M)$. As an application, they are able to decompose any $f \in L^2(G/G_0, \sigma)$ into eigenfunctions of invariant 'differential' operators on a homogeneous space G/G_0." No proofs are given.

J. M. G. Fell (Seattle, Wash.)

Maurin, K. 5959

A theory of characters. Harmonic analysis on connected type I-groups.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **11** (1963), 587–592.

This paper continues the preceding one [#5958]. Let G be a connected, separable, locally compact group, and $D(G)$ the nuclear space of "generalized C^∞ functions with compact support" on G. Let B be a kernel (i.e., a separately continuous bilinear form on $D(G) \times D(G)$) which is invariant (i.e., $B(g\varphi, g\psi) = B(\varphi, \psi)$ for $g \in G$, $\varphi, \psi \in D(G)$) and positive Hermitian. It is shown (Theorem 2.2) that B is a direct integral of positive invariant kernels B_λ which induce factor (or irreducible) representations and which are "eigenkernels" of the central symmetric elements of the generalized enveloping algebra $E(G)$ of G. In particular, if the kernel B is a trace (i.e., positive, invariant and central), we can make the B_λ be characters, that is, traces which induce factor representations (Theorem 3).

If G is unimodular and of Type I, the integral decomposition of B can be taken over the dual space $\hat{G}$ of G, that is, the Borel space of all equivalence classes of irreducible unitary representations (Theorem 4.1).

Proofs are given in compressed form.

G. I. Kac [Trudy Moskov. Mat. Obšč. **12** (1963), 259–301; MR **28** #164] asked whether two different definitions of finite ring groups are equivalent. The present paper answers this question affirmatively.

M. Greendlinger (Ivanovo)

Kobayashi, Shoshichi; Nagano, Tadashi 5961

On filtered Lie algebras and geometric structures. I.

J. Math. Mech. **13** (1964), 875–907.

Cet article donne les démonstrations d'une partie des résultats annoncés dans une note antérieure [Bull. Amer. Math. Soc. **70** (1964), 401–403; MR **29** #196]. Ces résultats concernent les algèbres de Lie L de dimension finie sur un corps k de caractéristique 0 filtrées par une suite de sous-algèbres $L = L_{-1} \supset L_0 \supset L_1 \supset L_2 \supset \cdots$, avec $[L_p, L_q] \subset L_{p+q}$; c'est la situation qui se présente dans l'étude en un point d'une algèbre de Lie de champs de vecteurs sur une variété différentiable. On suppose donné un groupe A d'automorphismes de L laissant chaque L_p stable. On suppose que l'algèbre L et le groupe A vérifient les conditions suivantes: (a) dans l'algèbre de Lie graduée associée à L, L/L_0 est une sous-algèbre commutative maximale, (b) dans L, considéré comme module sur L_0, L_0 est maximal dans l'ensemble des sous-modules stables par A et distincts de L, (c) $L_1 \neq (0)$. Les auteurs démontrent qu'avec ces hypothèses: (1) $L_p = (0)$ pour $p > 1$, (2) L est semi-simple et n'admet pas d'idéal non trivial stable par A, (3) il existe un élément $e \in L$ et un seul tel que $\operatorname{Ker}(\operatorname{ad}(e) - p)$ soit un supplémentaire de L_{p+1} dans L_p ($p = -1, 0, 1$). Si $k = \mathbf{R}$ et si A est contenu dans la composante connexe neutre du groupe des automorphismes de L, alors L est simple et contient une sous-algèbre compacte maximale K stable par $\operatorname{ad}(e)^2$. L'élément e est alors orthogonal à K pour la forme de Killing de L. Les auteurs donnent ensuite la liste des classes de couples (L, e), où L désigne une algèbre de Lie réelle simple et e un élément de L tel que $\operatorname{ad}(e)$ soit semi-simple et admette pour seules valeurs propres: -1, 0 et 1 (deux couples (L, e) et (L', e') sont dans la même classe s'il existe un isomorphisme θ de L sur L' tel que $\theta(e) = e'$). Pour une algèbre L classique, les éléments e sont donnés explicitement en termes de matrices. Dans le cas général, ils sont déterminés à partir du diagramme de Satake de L.

J. L. Koszul (Grenoble)

Kuranishi, M.; Rodrigues, A. M. 5962

Quotients of pseudo groups by invariant fiberings.

Nagoya Math. J. **24** (1964), 109–128.

A basic technical problem in the theory of pseudogroups is that of passing to the "quotient space" of a representation. Roughly speaking, let Γ be a pseudogroup acting on a fiber space (M, M', ρ), where M and M' are differentiable manifolds and ρ is the projection of M onto the base M'. Suppose every element of Γ preserves the fibration. Then each $f \in \Gamma$ induces a locally defined transformation f' on M'. Does the collection of such f' form a pseudogroup on M'? The difficulty is that $f' \circ g'$ may be defined while $f \circ g$ is not, because we can have range $g' \subset$ domain f' without having range $g \subset$ domain f. The authors show by example that one can have an analytic intransitive pseudogroup acting on an M such that the induced family on M' is not a pseudogroup. Their main theorem asserts that for a real analytic transitive continuous pseudogroup the induced family of transformations is indeed a pseudogroup. The proof uses the celebrated Cartan-Kuranishi prolongation theorem.

W. H. Fleming (Providence, R.I.)

Burkill, H. 5965

A note on rearrangements of functions.

Amer. Math. Monthly 71 (1964), 887–888.

For $0<x<1$, let the real-valued functions f and g be non-increasing and left-continuous. If for all real numbers A, the intervals $\{x: f(x) \geq A\}$ and $\{x: g(x) \geq A\}$ have the same length, then the author shows $f(x) = g(x)$ for $0<x<1$. Thus left-continuity specifies uniquely that non-increasing function which is equimeasurable with a given measurable function.

G. Freilich (New York)

Bruckner, A. M. 5966

Stationary sets for certain classes of derivates of Darboux functions.

Michigan Math. J. 11 (1964), 305–309.

The author proves several interesting theorems that generalize the basic result of elementary calculus, which states that a differentiable function f whose derivative vanishes on an interval $[a, b]$ must be constant on $[a, b]$. A set is called totally imperfect if it contains no non-empty perfect subsets. Let $\mathscr{C}$ be a class of functions defined on $[a, b]$. A set $E \subset [a, b]$ is called a stationary set for $\mathscr{C}$ provided every function in $\mathscr{C}$ that is constant on E is constant on $[a, b]$. Let $\mathscr{A}$ denote the class of approximate derivatives, finite or infinite, of Darboux functions; $\mathscr{D}$ the class of upper right Dini derivatives of Darboux-Baire functions; and $\mathscr{U}$ the class of upper derivatives of Darboux functions. It is proved that if E is a subset of $[a, b]$ whose complement in $[a, b]$ is totally imperfect, then E is a stationary set for each of the classes $\mathscr{A}$, $\mathscr{D}$, and $\mathscr{U}$. It is also shown that the only stationary set for the class of approximate derivatives of arbitrary approximately differentiable functions on $[a, b]$ (infinite values allowed for f_{ap}'), or for the class of Dini derivatives of arbitrary finite functions on $[a, b]$, or for the class of upper derivatives of arbitrary functions on $[a, b]$, is the interval $[a, b]$ itself.

S. Marcus (Bucharest)

Šmidov, F. I. 5967

Properties of the derivative numbers and approximative derivative numbers of a finite function. (Russian)

Sibirsk. Mat. Ž. 5 (1964), 679–711.

Soit E un ensemble réel borné. Convenons de dire qu'une fonction réelle finie f, définie sur E, jouit de la propriété (L) si $E = \bigcup_{n=1}^{\infty} E_n$ et, pour chaque n, f remplit une condition de Lipschitz sur E_n. On donne des conditions suffisantes, exprimées à l'aide des nombres dérivés—ordinaires ou approximatifs—afin que f jouisse de la propriété (L) sur E. Théorème 1: Supposons que f remplit, en chaque point de E, à l'exception possible d'un ensemble dénombrable, l'une au moins des quatre conditions suivantes:

(1) $\underline{f}^-(x) > -\infty$ et $\bar{f}^+(x) < \infty$;

(2) $\bar{f}^-(x) < \infty$ et $\underline{f}^+(x) > -\infty$;

(3) $-\infty < \underline{f}^-(x) \leq \bar{f}^-(x) < \infty$;

(4) $-\infty < \underline{f}^+(x) \leq \bar{f}^+(x) < \infty$.

Alors, f jouit de la propriété (L) sur E. Théorème 2: Supposons que f est mesurable sur E et qu'elle remplit en chaque point de E, à l'exception possible d'un ensemble dénombrable, l'une au moins des six conditions suivantes:

(1) $-\infty < \bar{f}_{ap}^+(x) < \infty$ et $\underline{f}_{ap}^-(x) > -\infty$;

(2) $\bar{f}_{ap}^+(x) < \infty$ et $-\infty < \underline{f}_{ap}^-(x) < \infty$;

(3) $-\infty < \underline{f}_{ap}^+(x) < \infty$ et $\bar{f}_{ap}^-(x) < \infty$;

(4) $\quad f_{ap}{}^{+}(x) > -\infty \quad$ et $\quad -\infty < \bar{f}_{ap}{}^{-}(x) < \infty;$

(5) $\quad -\infty < \underline{f}_{ap}{}^{+}(x) \leq \bar{f}_{ap}{}^{+}(x) < \infty;$

(6) $\quad -\infty < \underline{f}_{ap}{}^{-}(x) \leq \bar{f}_{ap}{}^{-}(x) < \infty.$

Alors, f jouit de la propriété (L) sur E. Le théorème 3 établit l'existence, pour toute fonction f mesurable, de certaines parties du graphique de f qui sont réunions dénombrables de courbes satisfaisant une condition de Lipschitz.

Les démonstrations sont extrêmement délicates et laborieuses. *S. Marcus* (Bucharest)

Ivanov, L. D. 5968

An estimate for the growth of smooth functions. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 1131–1134.

Let G be an open r-dimensional cube of side $N\varepsilon$, where N is a positive integer and $\varepsilon > 0$. Further, let $\lambda = s + d$, where s is a positive integer and $0 \leq d < 1$. The functions f considered are defined in G and possess partial derivatives of orders $\leq s$; moreover, their partial derivatives of order s are subject to a Hölder-Lipschitz condition of order α with constant M. For suitable positive k, K depending only on r, λ, the author shows that if an inequality of the type $|f(x)| \leq A(N\varepsilon)^{\lambda}$ holds at not less than kN^{r-1} points whose mutual distances are not less than ε, then a similar inequality holds throughout G, with A replaced by $K\cdot(A+M)$. *L. Mean oscillation over cubes and Hölder continuity.

Proc. Amer. Math. Soc. **15** (1964), 717–721.

By modifying a method due to John and Nirenberg [Comm. Pure Appl. Math. **14** (1961), 415–426; MR **24** #A1348], the author establishes, in the same order of ideas, an extremely convenient criterion for Hölder continuity in terms of the mean oscillation over cubes.

L. C. Young (Madison, Wis.)

Goldman, A. J. 5970

A generalization of Rennie's inequality.

J. Res. Nat. Bur. Standards Sect. B **68B** (1964), 59–63.

Let $\alpha_1, \alpha_2, \cdots, \alpha_n$ $(n > 1)$ be positive numbers with $\sum_{i=1}^{n} \alpha_i = 1$. For every sequence $(x_1, x_2, \cdots, x_n)$ with all $x_i > 0$ and for every real $t \neq 0$, consider the mean of order t, $M_t(x_1, x_2, \cdots, x_n) = (\sum_{i=1}^{n} \alpha_i x_i{}^t)^{1/t}$. Let $r < s$, $r, s \neq 0$, and consider the ratio (*) $M_s(x_1, \cdots, x_n)/M_r(x_1, \cdots, x_n)$. It is well known that this ratio is ≥ 1. Cargo and the reviewer [same J. **66B** (1962), 169–170; MR **26** #5110] have shown that if $0 < A < B$ and if each x_i is restricted to the closed interval $[A, B]$, then the above ratio is bounded above by

$$(**)\quad \left\{\frac{r(\gamma^s-\gamma^r)}{(s-r)(\gamma^r-1)}\right\}^{1/s}\left\{\frac{s(\gamma^r-\gamma^s)}{(r-s)(\gamma^s-1)}\right\}^{-1/r}, \qquad \gamma = B/A.$$

They have also given a necessary and sufficient condition for the equality of (*) and (**). The author gives an alternative proof of the results of Cargo and the reviewer, formulating them in a more general setting, where integration over a measure space of unit total measure replaces the finite sums defining the means. For his proof he gives first a generalization of a simple but elegant observation made by Rennie [Amer. Math. Monthly **70** (1963), 982], who gave a simple proof of (the integral form of) the Kantorovich inequality.

O. Shisha (Dayton, Ohio)

Beckenbach, E. F. 5971

On the inequality of Kantorovich.

Amer. Math. Monthly **71** (1964), 606–619.

Let $\alpha_1, \alpha_2, \cdots, \alpha_n$ $(n > 1)$ be positive numbers with $\sum_{i=1}^{n} \alpha_i = 1$. For every sequence $(x_1, x_2, \cdots, x_n)$ with all $x_i > 0$ and for every t, $-\infty \leq t \leq \infty$, consider the mean of order t, $M_t(x_1, x_2, \cdots, x_n)$, defined as $(\sum_{i=1}^{n} \alpha_i x_i{}^t)^{1/t}$ if $0 < |t| < \infty$, as $\prod_{i=1}^{n} x_i{}^{\alpha_i}$ if $t = 0$, as $\min_{1 \leq i \leq n} x_i$ if $t = -\infty$, and as $\max_{1 \leq i \leq n} x_i$ if $t = \infty$. It is known that

$$(*)\qquad M_s(x_1, x_2, \cdots, x_n)/M_r(x_1, x_2, \cdots, x_n) > 1$$

if $-\infty \leq r < s \leq \infty$, unless all the x_i are equal. Suppose that $c_1, c_2, \cdots, c_m$ $(1 \leq m < n)$ are given positive numbers. The author gives a lower bound for the function

$$(**)\quad \varphi(x_{m+1}, \cdots, x_n) \equiv \frac{M_s(c_1, \cdots, c_m, x_{m+1}, \cdots, x_n)}{M_r(c_1, \cdots, c_m, x_{m+1}, \cdots, x_n)} \qquad (-\infty \leq r < s \leq \infty),$$

from which he also derives (*). Let $0 < A < B < \infty$. Cargo and the reviewer [J. Res. Nat. Bur. Standards Sect. B **66B** (1962), 169–170; MR **26** #5110] have given an upper bound for $M_s(x_1, \cdots, x_n)/M_r(x_1, \cdots, x_n)$ (r, s fixed, $-\infty < r < s < \infty$), where each x_i ranges over the closed interval $[A, B]$, and a necessary and sufficient condition for the attainment of this bound. The author considers the function (**) for given r, s $(-\infty \leq r < s \leq \infty)$ and given positive c_i, derives an upper bound for it when the x_i lie in $[A, B]$, and gives a necessary and sufficient condition for the attainment of this bound.

Larman, D. G. 5972

The approximation of G_δ-sets, in measure, by F_σ-sets.

Proc. Cambridge Philos. Soc. **61** (1965), 105–107.

Let E and A $(E \supset A)$ be sets of type G_δ and F_σ, respectively, on the real line R. The author calls A a good approximation to E provided there exists a translation-invariant outer measure μ (on subsets of R) such that $\mu(E) > 0$ and $\mu(E - A) = 0$. Modifying a construction by Besicovitch [J. London Math. Soc. **29** (1954), 382–383; MR **15**, 943], he obtains a set E of type G_δ with the following property: If A is of type F_σ and $E \supset A$, then E can be covered by a countable family of translates of $E - A$. In particular, no set of type F_σ is a good approximation to E.

Extension of measures by continuity. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 639–650.

Let A be a Boolean subalgebra of a Boolean algebra B.

By a measure on A the author means a bounded, real-valued, finitely or countably additive function defined on A. He shows that such a measure determines a topology for the larger Boolean algebra B. If the measure has a certain property called regularity, then the operations of B are continuous in the topology determined by the measure. In this case the measure is uniformly continuous, as a real-valued function defined over A. Hence it may be extended in a unique manner to a continuous function on the closure of A in the topology of B. This extension is also bounded and additive.

The author shows that in some standard cases this extension coincides with the usual extensions of measures. In particular, the Jordan and Lebesgue measures and some of their generalizations are obtainable as continuous extensions. The author generalizes these results to measures which, instead of being real-valued, take their values either in a topological abelian group, or in the Boolean algebra of all subsets of a set, with the Stone topology. *O. Frink* (University Park, Pa.)

Helsel, R. G.; Pu, H. W. 5974

Transforming a set-valued integral.

Bull. Soc. Roy. Sci. Liège **33** (1964), 451–455.

Le présent article est un complément à un autre [même Bull. **33** (1964), 272–286; MR **30** #2116], où les auteurs ont défini pour des fonctions réelles une intégrale à valeurs dans l'ensemble $\underline{\mathfrak{X}}$ des parties non vides bornées (et semble-t-il, fermées, bien que ce ne soit pas dit explicitement) d'un espace de Banach $\mathfrak{X}$. Cette intégrale jouit des propriétés classiques de la convergence monotone et de la convergence dominée. Si T est une application linéaire et continue de $\mathfrak{X}$ dans un espace de Banach $\mathfrak{Y}$, on en déduit de manière naturelle une intégrale à valeurs dans $\underline{\mathfrak{Y}}$. Le résultat essentiel est que l'application $(f, T)\to I(f, T)$ est continue en ce sens que si $f_n\to f$ pour la convergence dominée et si $\|T_n-T\|\to 0$, $I(f_n, T_n)\to I(f, T)$. On souhaiterait connaître des applications de la théorie. *A. Revuz* (Poitiers)

Henstock, Ralph 5975

The integrability of functions of interval functions.

J. London Math. Soc. **39** (1964), 589–597.

This paper is concerned with the concepts (introduced by the author) of variational equivalence and variational integration of pairs of interval functions. In the first theorem ξ is a function on the plane or its positive quadrant; for $j=1, 2$, $\mathbf{h}_j=\{h_{lj}, h_{rj}\}$ is a pair of interval functions variationally equivalent to $\mathbf{k}_j=\{k_{lj}, k_{rj}\}$; and $a_s=\xi(h_{s1}, h_{s2})$, $b_s=\xi(k_{s1}, k_{s2})$ $(s=l, r)$. It is shown that $\mathbf{a}=(a_l, a_r)$ is variationally equivalent to $\mathbf{b}=(b_l, b_r)$ if either ξ is such that always $|\xi(y_1, y_2)-\xi(x_1, x_2)|\leq |y_1-x_1|+|y_2-x_2|$, or else $\mathbf{h}_1$, $\mathbf{h}_2$ are variationally integrable and ξ satisfies a less stringent, but more complicated, continuity condition. In the second theorem a condition is given for $\mathbf{a}$ to be variationally integrable. By using particular ξ's the author then improves a number of results given in his book *Theory of integration* [Butterworths, London, 1963; MR **28** #1274]. The final theorem, also based on the first two, is the following. If f_1, f_2 are non-negative point functions, h_l, h_r are non-negative interval functions and, for $j=1, 2$, $(V)\int_a{}^b f_j\,d\mathbf{h}$ exists, then $(V)\int_a{}^b f_1{}^t f_2{}^{1-t}\,d\mathbf{h}$ exists for every t in $(0, 1)$. When $\mathbf{h}$ is variationally integrable, then $(V)\int_a{}^b f_1{}^t\,d\mathbf{h}$ also exists for every t in $(0, 1)$. *H. Burkill* (Sheffield)

Marcus, Solomon 5976

On a paper by B. K. Lahiri.

Bull. Calcutta Math. Soc. **55** (1963), 127–129.

The author first gives an elementary proof that if f is differentiable and the set Z of zeros of f' is everywhere dense, then f' is Riemann integrable on no subinterval of the domain if and only if the complement of Z is everywhere dense. He then proves the analogue for the approximate derivative of an approximately continuous function that has a finite approximate derivative at each point. *R. P. Boas, Jr.* (Evanston, Ill.)

Chacon, R. V. 5977

Ordinary means imply recurrent means.

Bull. Amer. Math. Soc. **70** (1964), 796–797.

Let X be a σ-finite measure space, T a positive linear operator from $L_1(X)$ to $L_1(X)$ with $\|T\|\leq 1$. Let $\{w_k\}$ be a sequence of non-negative numbers with $\sum_1{}^\infty w_k=1$. Define $u_n=\sum_1{}^n w_i u_{n-i}$, $u_0=1$. For any f and p in $L_1(X)$, $p\geq 0$, define $Q_n(f, p)=Z_n(f)/Z_n(p)$, where $Z_n(g)=\sum_0^{n-1} u_k T^k g$. Theorem: The ratios $Q_n(f, p)$ have a finite limit a.e. on the set where $\sum_0{}^\infty u_k T^k p>0$. The same assertion, on the set where $p>0$, was announced by G. E. Baxter [Notices Amer. Math. Soc. **11** (1964), 464]. The stronger version stated above is obtained directly from the general ergodic theorem of R. V. Chacon and D. S. Ornstein [Illinois J. Math. **4** (1960), 153–160; MR **22** #1822], which is a special case of it. *J. C. Oxtoby* (Bryn Mawr, Pa.)

Sulle funzioni di fase isocrone. (English and French summaries)

Rend. Mat. e Appl. (5) **22** (1963), 371–381.

From the author's summary: "A single but expressive kinematical description is given for the time average of a phase function. This description leads to a sufficient condition for ergodicity. The main properties of the phase function which satisfies such a condition are studied." *G.-C. Rota* (Cambridge, Mass.)

Sarymsakov, T. A. 5979

On the general ergodic theory. (Russian)

Dokl. Akad. Nauk SSSR **159** (1964), 25–27.

Notation and terminology are as in Antonovskiĭ, Boltjanskiĭ and the author [*Topological semifields* (Russian), Izdat. Samarkand. Gos. Univ., Tashkent, 1960; MR **25** #2461]. Let X be a normed space over the semifield R_Δ, and let G be a semigroup of linear operators carrying X into itself. Let Ω be the family of all finite subsets of Δ. A set $\{A_\alpha\}_{\alpha\in\Omega}$ of linear operators carrying X into itself is called a basic Ω-system for G if for all $x\in X$ and $T\in G$,

$$\lim_\alpha \|TA_\alpha x-A_\alpha x\| = \lim_\alpha \|A_\alpha Tx-A_\alpha\| = 0.$$

The norm in X has values in K_Δ. The semigroup G is called ergodic if it admits at least one basic Ω-system.

Next, a norm $\|A\|$ for linear operators A on X is defined; this norm is a certain mapping of K_Δ into K_Δ.

Several theorems are announced without proof; the following is typical. If A is a commutative set of operators with a common bound on their norms, then the semigroup generated by A is ergodic.

Roos, B. W. 5980

Note on generalized dynamical systems.

SIAM Rev. **6** (1964), 269–274.

This note presents a phase flow description of generalized dynamical systems. This description is advantageous for the theoretical investigation of these systems and for the proofs of general theorems. After introducing the concept of regional recurrence, a criterion is given for the ergodicity of a dynamical system which is reversible and measure-preserving.

W. Sangren (San Diego, Calif.)

Gähler, Werner 5981

Der innere Flächeninhalt.

Math. Nachr. **28** (1964), 67–110.

In der vorliegenden Arbeit werden die in einer früheren Publikation [dieselben Nachr. **26** (1963), 181–228; MR **29** #3610] begonnenen Untersuchungen fortgesetzt. Die dort getroffenen Vereinbarungen werden übernommen, die eingeführten Begriffe verwendet. Ein Polyeder $S: p|M_\pi$ ($\pi \in \Pi$) heisst "Unterpolyeder einer eigentlichen Fläche" $S': p'|M_{\sigma'}$ ($\sigma' \in \Sigma$) wenn folgendes gilt: Zu jeder offenen Überdeckung des Trägers $[S]$ von S gibt es ein Element $\pi' \in \Pi$ und eine Abbildung $f \in F_{\pi\pi'}$, so dass $\sigma_{\pi'} = \sigma$ ist und zu jedem Paar von Punkten $t \in M_\pi$, $t' \in M_{\pi'}$, mit tft' die Bildpunkte $p(t)$ und $p'(t')$ stets beide gemeinsam einer gewissen Menge aus der Überdeckung angehören. Sätze 1 und 2 und das Korollar zu Satz 2 liefern mehrere Bedingungen, die notwendig und hinreichend dafür sind, dass ein Polyeder Unterpolyeder einer eigentlichen Fläche ist. Ein Polyeder S^* heisst in der eigentlichen Fläche $S: p|M_\sigma$ ($\sigma \in \Sigma$) bezüglich $p|M_\pi$ einbeschrieben, wenn S^* als eine Darstellung die Einschränkung $p|M_\pi$ von p über einem Raum M_π ($\pi \in \Pi$) mit $\sigma_\pi = \sigma$ besitzt. Wie aus Satz 3 folgt, ist ein Polyeder genau dann Unterpolyeder einer eigentlichen Fläche S, wenn es in S bezüglich mindestens einer Darstellung von S einbeschrieben ist. Ähnlich wie mit den Flächen werden vier Kurvenarten erklärt, je nach dem ebenen Urbild der Kurvendarstellung: orientierte und nicht orientierte, berandete und geschlossene Kurven. Die orientierte berandete Kurve steht im engen Zusammenhang mit dem im Artikel von S. Gähler und dem Verfasser [ibid. **22** (1960), 175–203; MR **24** #A444] eingeführten Kurvenbegriff. Die meisten für Flächen aufgestellten Aussagen lassen sich auf die in der vorliegenden Arbeit definierten Kurven übertragen. Satz 11 drückt eine wichtige Konvergenzaussage für eine Folge von Polygonen gegen eine eigentliche Kurve aus, mit deren Hilfe in Satz 18 unter gewissen Voraussetzungen eine ähnliche Aussage für Flächen bewiesen wird. Ähnlich wie im Fall des äusseren Flächeninhalts definiert Verfasser eine allgemeine Inhaltsfunktion β und gibt für sie Aussagen an. Der innere Flächeninhalt wird wie der äussere Flächeninhalt mittels eines Tripelmasses definiert, mit dem einzigen Unterschied, dass jetzt lediglich Unterpolyeder der betreffenden Fläche zur Inhaltsdefinition zugelassen sind. Die Aussagen über β werden dann zu Aussagen über den inneren Flächeninhalt spezialisiert. Unter anderem ergibt sich dabei, dass der innere Flächeninhalt unter gewissen Voraussetzungen subadditiv ist.

On linear measure of projections of two-dimensional sets to arbitrary straight line.

Natur. Sci. Rep. Ochanomizu Univ. **15** (1964), 33–40.

For a set E in the plane let $f(\theta)$ denote the linear measure of the orthogonal projection of E onto a straight line having direction θ. It is shown that if E is a bounded open set, then $f(\theta)$ is lower semicontinuous but not necessarily upper semicontinuous; if E is a bounded closed set, then $f(\theta)$ is upper semicontinuous but not necessarily lower semicontinuous.

P. V. Reichelderfer (Columbus, Ohio)

Vinti, Calogero 5983

Perimetro—variazione.

Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 201–231.

For symmetric density functions (or "nuclei") the author gives a more general setting and stronger results on approximation theory along the lines of a recent joint paper with the reviewer [E. Baiada and C. Vinti, Ann. Mat. Pura Appl. (4) **62** (1963), 1–58; MR **28** #4076]. Moreover, if H is the class of "nuclei" $h(r, s, t)$, $0 \leq r < s < +\infty$, $t \in S_s$, such that (i) $h(r, s, t) \geq 0$, (ii) $\int_{S_s} h\, dt = 1$, (iii) for any s and positive δ, $\lim_{r \to s-0} \int_{|t| \geq \delta} h(r, s, t)\, dt = 0$, (iv) $f^* h$ is locally of class B_1 of J. W. Calkin and C. B. Morrey [J. W. Calkin, Duke Math. J. **6** (1940), 170–186; MR **1**, 208; C. B. Morrey, ibid. **6** (1940), 187–215; MR **1**, 209], then $\max \lim_{r \to s-0} \int_{S_s} |\text{grad } f^* h|\, dx$, called the "perimeter" of f, is independent of s in $(0, +\infty)$ and of h in H. This invariant coincides with Fréchet continuation of the variation functional to (L) and is then lower semicontinuous [cf. also E. De Giorgi, Ann. Mat. Pura Appl. (4) **36** (1954), 191–213; MR **15**, 945]. When nuclei are of compact support in S_2 an approximation theorem in area (in the generalized sense given by L. Cesari [Ann. Scuola Norm. Sup. Pisa (2) **5** (1936), 299–313]) and in S_1 an approximation theorem in length (in the generalized sense of C. Goffman [Rend. Circ. Mat. Palermo (2) **2** (1954), 203–235; MR **16**, 457]) are obtained. Also given are examples of some of the most important "nuclei" with their properties.

E. Baiada (Modena)

Federer, Herbert 5984

Some theorems on integral currents.

Trans. Amer. Math. Soc. **117** (1965), 43–67.

As the title suggests, this paper contains several different theorems concerning integral currents. We shall use the notation of the basic reference [the author and W. H. Fleming, Ann. of Math. (2) **72** (1960), 458–520; MR **23** #A588] throughout. Perhaps the most important results, which have already had significant applications, concern the slicing of a normal current T in a differentiable manifold X by a locally Lipschitzian map $f: X \to R^n$. With almost every point $y \in R^n$ there is associated, by means of relative differentiation of measures, a normal current $\langle T, f, y \rangle$ of dimension $\dim(T) - n$, which can be thought

of as the slice of T in $f^{-1}\{y\}$. In case T is integral, $\langle T, f, y\rangle$ will also be integral. Slicing has many other natural properties, e.g.,

$$\langle T, f, u\omega_n\rangle\ (= T \wedge f^{\#}(u\omega_n) \wedge \gamma) = \int_{R^n} \langle T, f, y\rangle(\gamma)\cdot u(y)\, dL_n$$

whenever $u: R^n \to R$ is a bounded Baire function and $\gamma \in \mathbf{E}^{k-n}(X)$. The author also establishes two sets of sufficient conditions to make the slicing function $\langle T, f, \cdot\rangle: R^n \to \mathbf{I}_k(X)$ M-bounded and F-continuous.

A second result of this paper is a new measure-theoretic characterization of integral currents. Suppose $T \in \mathbf{E}_k(R^n)$ and $U, V \in \mathbf{E}_{k-1}(R^n)$ with $\partial T = U + V$. If T is rectifiable, $\mathbf{M}(U) < \infty$, and $\mathbf{H}^{k-1}(\text{spt } V) = 0$, then $\mathbf{M}(\partial T) < \infty$; hence $T \in \mathbf{I}_k(R^n)$.

The author now gives a very short proof of Wirtinger's inequality, from which it follows that on a Kähler manifold integral currents with almost everywhere complex tangent spaces are minimal currents. Using the characterization of integral currents above, one sees that each complex algebraic variety of complex dimension k on a Kähler manifold X is naturally a minimal (locally) integral current of dimension $2k$ on X. The following striking fact is a consequence. In the higher-dimensional versions of the problem of Plateau (now formulated in terms of minimal currents), not only will singularities ordinarily arise in the solutions, but, in particular, every singularity of a complex algebraic variety can occur. The author solicits other examples of minimal currents with interesting singularities.

Finally it is proved that the plane sections of a variety depend continuously, as currents, on the cutting planes and that the algebraic geometric description of tangent cones at singular points is equivalent, for complex varieties, to the purely measure-theoretic device used in the theory of minimal currents.

F. J. Almgren, Jr. (Princeton, N.J.)

Young, L. C. 5985

Some extremal questions for simplicial complexes. II. On the "radius times periphery" problem for area.

Rend. Circ. Mat. Palermo (2) **11** (1962), 271–279.

Part I appeared in same Rend. (2) 11 (1962), 178–184 [MR 27 #2609]. Let Π be a 2-dimensional polyhedron, let h be the supremum of all ρ such that any relative cycle on Π of diameter less than ρ is null-homotopic, and let L be the length of the shortest system of cuts on Π whose complement is a polyhedral disk. Then

$$A \geq \frac{\varepsilon}{14} L^{1-\varepsilon} h^{1+\varepsilon},$$

where A is the area of Π and ε is arbitrary, subject to $0 < \varepsilon < \frac{1}{2}$.

W. H. Fleming (Providence, R.I.)

Young, L. C. 5986

Some extremal questions for simplicial complexes. III. Problems of the geometry and analysis of the higher Euclidean spaces.

Rend. Circ. Mat. Palermo (2) **12** (1963), 41–58.

Part II is reviewed above [#5985]. If Π is a closed, oriented k-polyhedron in n-space R^n and j_ν is the k-vector of the νth face of Π, then it is an elementary fact that $\sum_\nu j_\nu = 0$. The converse is shown to be nearly correct in the following sense. Let $j_1, \cdots, j_N$ be decomposable k-vectors such that $j_1 + \cdots + j_N = 0$. Then given $\varepsilon > 0$ there exist k-polyhedra Π_ε^1, Π_ε^2 such that $\Pi_\varepsilon = \Pi_\varepsilon^1 + \Pi_\varepsilon^2$ is closed, Π_ε^2 has k-area less than ε, the k-vector of every face of Π_ε^1 is a positive scalar multiple $a_{\mu\nu}$ of some j_ν, and $1 = \sum_\mu a_{\mu\nu}$. When $k = n-1$, one can arrange that Π_ε is the image of a k-sphere (for $n = 3$ see the author's paper [Bull. Soc. Math. France **79** (1951), 59–84, p. 71; MR **13**, 731]). It is an open question (when $2 \leq k \leq n-2$) under what general conditions one can take Π_ε to be the image of a k-sphere. However, this is shown to be possible in the special case $j_\nu = J_\nu - J_{\nu-1}$, where $J_0, J_1, \cdots, J_N$ are decomposable k-vectors and $J_0 = J_N$.

In a similar way, let $j_1, \cdots, j_N$ be decomposable k-vectors such that $j = j_1 + \cdots + j_N$ is decomposable. Let Δ be a k-simplex with k-vector j. Then given $\varepsilon > 0$ there exist Π_ε^1, Π_ε^2 as above and a positive integer m_ε such that $m_\varepsilon \partial\Delta = \partial\Pi_\varepsilon$, $m_\varepsilon = \sum_\mu a_{\mu\nu}$. When $2 \leq k \leq n-2$ it is an open question under what general conditions one may take $m_\varepsilon = 1$ and Π_ε an image of a k-disc. This problem is closely related to that of the appropriate Weierstrass condition for multiple integral variational problems in parametric form.

W. H. Fleming (Providence, R.I.)

Fleming, W. H.; Young, L. C. 5987

Some extremal questions for simplicial complexes. IV. The algebraic and the geometric resultant, an application of variational methods.

Rend. Circ. Mat. Palermo (2) **12** (1963), 200–210.

A k-integrand is a real-valued continuous function $f(x, \alpha)$ subject to the homogeneity condition $f(x, t\alpha) = tf(x, \alpha)$ for $t \geq 0$, where x is a point in Euclidean n-space and α is a k-vector in n-space. A generalized k-variety is a linear functional L on the space of k-integrands such that $L(f) \geq 0$ whenever $f \geq 0$. A micro-polytope concentrated at x_0 is a variety of the special form $L(f) = \int f(x_0, \alpha)\, d\mu$, where μ is a measure on the unit sphere $|\alpha| = 1$ which vanishes on the complement of a finite set of unit k-vectors.

If $F(x, \alpha) = \alpha$, write $L(F)$ for the k-vector with components $L(F_\lambda)$, where F_λ are the components of F. $L(F)$ is called the flux of L, and in the case $L(F)$ is a simple k-vector, it is termed the resultant flux.

The main result of the paper is the following theorem. Let L be a k-dimensional micro-polytope concentrated at x_0 with resultant flux α_0. For a suitable subsequence $n = n_1, n_2, \cdots$ of the positive integers, there exists a polytope Π_n, whose boundary coincides with that of n repetitions of an oriented k-simplex Δ_n with flux α_0/n, such that if $L_n(f) = \Pi_n(f_0)$, where $f_0(x, \alpha) = f(x_0, \alpha)$, then L is the strong limit of L_n in the sense that the total variation of the difference of the measures that define L and L_n tends to zero. This result then leads to the theorem announced above [#5986], namely, every system of multivectors which possesses the algebraic resultant α_0 possesses also the geometric resultant α_0, and vice versa.

★**Studies of the modern problems of the constructive theory of functions [Исследования по современным проблемам конструктивной теории функций].** 5988

A collection of papers edited by V. I. Smirnov.

Gosudarstv. Izdat. Fiz.-Mat. Lit., Moscow, 1961. 368 *pp*. 1.28 *r*.

This volume contains the reports presented at a conference on the constructive theory of functions held in 1959 in Leningrad. Some of the papers will be reviewed individually.

Günter, N. M. [Gjunter, N. M.]; Kusmin, R. O. 5989

★**Aufgabensammlung zur höheren Mathematik. Band II.**

Zweite, berichtigte Auflage. Hochschulbücher für Mathematik, Band 33.

VEB Deutscher Verlag der Wissenschaften, Berlin, 1963. vi+289 *pp*. *DM* 19.60.

Volume I (1957) was reviewed earlier [MR **19**, 236]. The present volume contains Chapters 11–17 dealing with partial differential equations, infinite series, approximation theory, functions of a complex variable, the equations of mathematical physics, the calculus of variations, and the theory of probability. Solutions of the problems are given at the end of the book.

Tomić, Boško S. 5990

Les relations asymptotiques pour les zéros croissant indéfiniment des polynomes à coefficients positifs.

Acad. Roy. Belg. Bull. Cl. Sci. (5) **49** (1963), 799–818.

By use of certain asymptotic relations, the author proves the following theorems for polynomials $P_p(z)=\sum_{\nu=0}^{p} a_\nu z^{p-\nu}$ with positive real a. (1) If P_p has some real zeros, the smallest real zero $r_p\to-\infty$ as $a_0\to+0$. (2) If P_p has no real zeros, certain pairs of conjugate imaginary zeros will approach real values of which the smallest will tend to $-\infty$ as $a_0\to+0$.

(3) $r_3<r_5<\cdots<r_{2n-1}<r_{2n}<r_{2n-2}<\cdots<r_2<0$.

On "small" coefficients of the power series of entire functions.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 27–38.

In a previous paper [Acta Math. Acad. Sci. Hungar. **7** (1956), 145–150; MR **18**, 201] the second author proved the following theorem (Theorem A), based on a conjecture of G. Pólya. Let $f(z)=\sum a_n z^n=\sum b_n(z-1)^n$ be the power series expansions of the entire transcendental function $f(z)$ around the points $z=0$ and $z=1$. Let $Z_0(n)$ and $Z_1(n)$ denote the number of zeros in the sequences $a_0, a_1, \cdots, a_{n-1}$ and $b_0, b_1, \cdots, b_{n-1}$, respectively. Then, as $n\to\infty$, $\liminf([Z_0(n)+Z_1(n)]/n)\le 1$.

In the present paper the authors generalize Theorem A to the following theorem (Theorem 1). Let $f(z)$ be as in Theorem A and let $g(z)=\sum c_n z^n$ be an arbitrary entire function. Let $\mu_f(r)$ and $\mu_g(r)$ denote $\max_n(|a_n|r^n)$ and $\max_n(|c_n|r^n)$, respectively. Let $S_0(n)$ and $S_1(n)$ denote the number of indices $k<n$ for which $|a_k|\le|c_k|$ and $|b_k|\le|c_k|$, respectively. If for some δ, $0<\delta<1$, $\mu_f(r^{1/\delta})/\mu_g(r)$ fails to approach ∞ as $r\to\infty$, then $\liminf([S_0(n)+S_1(n)]/n)\le 1+2\delta$. By specializing to $g(z)\equiv 0$, Theorem 1 becomes Theorem A. Furthermore, by the use of the well-known relations which connect $\mu_f(r)$ and $\mu_g(r)$ with the orders ρ_f and ρ_g of $f(z)$ and $g(z)$, respectively, Theorem 1 gives $1+2\rho_f/\rho_g$ as an upper estimate for the limes inferior of Theorem 1. However, the authors succeed by a special device in improving this upper estimate by replacing it by $1+\rho_f/\rho_g$ (Theorem 4). Two more theorems of the type of Theorem 1 are proved, in one of which two "comparison functions", $g_1(z)$ and $g_2(z)$, are used. Finally, an example of a pair of functions $f(z)$ and $g(z)$ is given which shows that, in general, the estimate $1+\rho_f/\rho_g$ of Theorem 4 cannot be replaced by a smaller number.

The proofs are elementary and in part based on Johansen's general interpolation formula for polynomials [Skand. Aktuarietidskr. **14** (1931), 231–237].

Staniszewska, J. 5992

Sur l'ensemble des points de divergence des séries entières continues sur la circonférence du cercle de convergence.

Fund. Math. **54** (1964), 305–324.

It was shown by J. Śladkowska [Fund. Math. **49** (1960/61), 271–294; MR **23** #A2700; C. R. Acad. Sci. Paris **250** (1960), 258–259; MR **22** #161] that if E is a set of type $G_{\delta\sigma}$ and a subset of a set Φ of logarithmic measure zero and type F_σ, then there exists a continuous function whose Fourier series has E as its set of divergence. (A set is of logarithmic measure zero if it can be covered by denumerably many open intervals of lengths $L_i<1$ such that $\sum_i 1/\log(1/L_i)$ is arbitrarily small.)

The present paper contains a result, similar to the above, for "continuous power series", that is, for power series $H(z)=\sum_n a_n z^n$, such that the power series converges for $|z|<1$ and $H(z)$ is continuous for $|z|\le 1$. The author first proves the following lemma: Given a set E on the circumference of the unit circle, E of type G_δ, $\bar{E}$ of logarithmic measure zero, there exists a continuous power series whose partial sums are uniformly bounded on $|z|=1$, which diverges on E and converges on the complement of E. From this lemma the author derives the following theorem. Let E be a set on the circumference of the unit circle, E of type $G_{\delta\sigma}$, $E\subset\Phi$, where Φ is of logarithmic measure zero and of type F_σ. There exists a continuous power series whose partial sums are uniformly bounded on $|z|=1$, which diverges on E and converges on the complement of E. *F. Herzog* (E. Lansing, Mich.)

Grunsky, Helmut 5997

Über Extremaleigenschaften gewisser konformer Normalgestalten mehrfach zusammenhängender Gebiete.

J. Math. Pures Appl. (9) **43** (1964), 27–47.

Consider a bounded domain D of connectivity p in the complex z-plane. We suppose that the outer boundary curve Γ_0 of D has capacity 1. Let $P(z)=z^{p-1}+\cdots$ be a normalized polynomial of degree $p-1$ which has in each bounded complementary component D_ρ of D $(\rho=1,\cdots,p-1)$ precisely one zero b_ρ. We denote the discriminant of $P(z)$ by d and the mapping radius of D_ρ relative to b_ρ by r_ρ; form the expression $E(P)=|d|^2\prod_{\rho=1}^{p-1} r_\rho$. This expression is bounded for all conformally equivalent domains D of this type and all such polynomials $P(z)$. The maximum is achieved for a domain $\hat{D}$ and a polynomial $\hat{P}(z)$ such that the outer boundary of $\hat{D}$ satisfies $|\hat{P}(z)|=1$ and all outer boundary curves of $\hat{D}$ satisfy $|\hat{D}(z)|=C_\rho$ $(\rho=1,\cdots,p-1)$. We also have $E(\hat{P})=\prod_{\rho=1}^{p-1} C_\rho$. The theorem characterizes by an extremal property the well-known canonical map of a multiply connected domain onto a domain bounded by a set of lemniscates. Such canonical domains were introduced by de La Vallée Poussin and Julia and have been more recently studied by Walsh, Jenkins and Landau. The proof of the above theorem is based on the Dirichlet integral technique for the Green's function and the harmonic measures which lead to an inequality between the Green's functions of a domain and an included domain. This inequality is used to estimate the capacity of multicomponent sets in terms of simple geometric quantities.

Kleiner, W. 5998b

Sur la détermination numérique des points extrémaux de Fekete-Leja.

Ann. Polon. Math. **15** (1964), 91–96.

Let C be a simple closed curve (or an arc) of bounded curvature in the z-plane, and let D be the exterior domain bounded by C. Let E_n be a set of n^2 points dividing C approximately into n^2 equal arcs: $\theta^{-1}\leq n^2L_i/L\leq\theta$, where L_i is the length of the ith subarc, L is the length of C and $\theta\geq 1$ is a constant. Let $z_{n1},\cdots,z_{nn}$ be the subset of n distinct points of E_n which minimizes $\prod_{i\neq k}|z_i-z_k|$ among all such subsets, and let $h_n(z)=[\prod_{k=1}^{n}(z-z_{nk})]^{1/n}$ ($h_n(z)/z\to 1$ as $z\to\infty$). In the second paper it is shown that, as $n\to\infty$, $h_n(z)$ converges to the normalized conformal mapping $f(z)$ of D onto the exterior of a circle. The result depends on potential-theoretic lemmas established in the first paper and on another paper by the author [Ann. Polon. Math. 14 (1963/64), 131–140; MR 28 #4132]. The author stresses the value of the main result for numerical methods of conformal mapping. The papers also contain estimates of error and approximate methods for the inverse mapping.

Suvorov, G. D. 5999

Metric properties of planar univalent mappings of closed regions. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 802–805.

The author considers plane homeomorphisms T of class BL_k, that is, with Dirichlet norm $\leq k$. Distortion theorems for regions D are obtained in terms of the relative distance $\rho(z_1,z_2;D)$ between points $z_1,z_2\in D$. For the definition of ρ the reader is referred to the author's paper [Sibirsk. Mat. Ž. 1 (1960), 492–522; MR 28 #210]. The basic theorem stated in the paper is of the following type. Suppose D and $\Delta=T(D)$ contain disks of radii δ_0, δ_1, respectively. Then whenever $\rho(t_1,t_2;\bar{D})$ is less than a certain number depending on k, δ_0 and δ_1, we have

$$\varphi_1[\rho(t_1,t_2;\bar{D})] < \rho[T(t_1),T(t_2);\bar{\Delta}] < \varphi_2[\rho(t_1,t_2;\bar{D})].$$

φ_1 are explicitly given. The tildes denote closure with respect to the prime-end topology. The author also states a result for the distortion of distance between sets, making use of the Hausdorff definition [*Mengenlehre*, pp. 145–146, Dover, New York, 1944; MR 7, 419].

Wu, Xue-mou [Wu, Hsueh-mou] 6000

On Bieberbach polynomials.

Acta Math. Sinica **13** (1963), 145–151 (*Chinese*); *translated as Chinese Math.* 4 (1963), 161–168.

The author presents proofs of several results on the approximation by polynomials of analytic functions, in particular, on the approximation by the Bieberbach polynomials $B_n(z)$ of the normalized mapping function $\phi(z)$ of a simply connected domain D on a disc. A particular result is an estimate

$$|\phi(z) - B_n(z)| = Cn^{-(m+1/2+\alpha)} \log n;$$

here the boundary Γ of D is assumed to be a smooth Jordan curve $z = z(s)$, s being arc length, for which $(d^m/ds^m) \arg z'(s)$ satisfies a Lipschitz condition of order α, $0 < \alpha < 1$, and C is a constant independent of n; for $\alpha = 1$ there is a similar conclusion with $\log n$ replaced by $(\log n)^2$. The proofs depend, in particular, on a previous paper of the author [Acta Math. Sinica 7 (1957), 271–276 (Chinese with German summary)].

Charzyński, Zygmunt; Śmiałkówna, Henryka 6001

The general equation of extremal functions with respect to any differentiated functional.

Bull. Soc. Sci. Lettres Łódź **12** (1961), *no.* 13, 16 *pp.*

Let F denote the family of functions $f(z) = \sum_1 a_n z^n$, $a_1 > 0$, a_n real, which are analytic and univalent in the unit disc and which satisfy $|f(z)| < 1$ there. Let F_T denote the subfamily of F such that $a_1 \geq T$, where T is fixed, $0 < T < 1$. Then the authors' result is the following one. Let $K(f)$ be a real functional defined in F_T, and with a Fréchet differential at every point of F_T, such that the differential $L(h)$ of $K(f)$ does not vanish identically at any point of F_T. Then every extremal function for the problem $\max[K(f)|f \in F_T]$ satisfies a certain differential equation. The equation and additional properties of the extremals are too complicated to reproduce in a brief review. Suffice it to note that these results are similar to those already obtained by Charzyński and Janowski [Ann. Univ. Mariae Curie-Skłodowska Sect. A 4 (1950), 41–56; MR 13, 122].

Kir'jackiĭ, È. G. [Kirjackis, E.] 6002

Some extremal problems in the classes $K_n(E)$ and $P(E)$. (Russian. Lithuanian and German summaries)

Litovsk. Mat. Sb. **3** (1963), *no.* 2, 83–90.

Let $K_n(E)$ be the class of functions $F(z)$ that are regular and single-valued in the unit disk E and satisfy the condition that the nth divided difference of $F(z)$ is never zero for arbitrary pairs of distinct points $z_0, z_1, \cdots, z_n$ in E. The class $P(E)$ is the set of all functions $f(z)$, $f(0) = 0$, $f'(0) = 1$, that are regular in E and satisfy the condition that $z^{n-1}f(z)$ belongs to $K_n(E)$. The author has shown previously [same Sb. **3** (1963), no. 1, 157–168; MR **29** #1328] that $f(z)$ has many extremal properties possessed by convex normalized univalent functions. For example, $|z|(1+|z|)^{-1} \leq |f(z)| \leq |z|(1-|z|)^{-1}$ and the Maclaurin coefficients a_k satisfy $|a_k| \leq 1$. In this paper he shows, among other things, that these bounds are not only sharp, but that equality is attained only for $f(z) = z(1-e^{i\alpha}z)^{-1}$, α real.

W. C. Royster (Lexington, Ky.)

Kir'jackiĭ, È. G. [Kirjackis, E.] 6003

An extension of some theorems of Aksent'ev and Čakalov to the class $K_n(D)$. (Russian. Lithuanian and German summaries)

Litovsk. Mat. Sb. **3** (1963), *no.* 2, 91–96.

The main result of this paper concerns the maximal K_n-domain of a class of functions. D is a maximal K_n-domain for a class Q of functions if each member of Q is regular in D and the nth divided difference of this member is never zero for arbitrary pairs of distinct points $z_0, \cdots, z_n$ in D, and in no domain containing D do the members of Q possess this property.

Let $C(\zeta, R)$ be the class of rational functions $f(z) = \sum_{k=1}^m A_k(z-a_k)^{-1}$, where $A_k > 0$, $\zeta, a_1, \cdots, a_m$ are complex constants with $|a_k - \zeta| \leq R$, $k = 1, 2, \cdots, m$. The author proves that the maximal K_n-domain for $C(\zeta, R)$ is the domain $G: |z-\zeta| > \mathrm{Re}[\sin(\pi/2(n+1))]^{-1}$. This result is generalized to the case where $f(z)$ is given by a Stieltjes integral, $f(z) = \int_{-\pi}^{\pi} (z-e^{it})\, d\alpha(t)$, $t \in [-\pi, \pi]$, $\alpha(t)$ nondecreasing and increasing at least at one point. The maximal K_n-domain is $|z| > [\sin(\pi/2(n+1))]^{-1}$. For $n = 1$ we get the maximal domain of univalence, a result obtained by Čakalov [Bŭlgar. Akad. Nauk. Izv. Mat. Inst. 4 (1960), no. 2. 43–55; MR **23** #A1022].

W. C. Royster (Lexington, Ky.)

Kocur, M. F. 6004

Some special classes of analytic functions in a circular annulus. I. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 4 (41), 79–85.

Let $P(z)$ belong to the class $C_q(\alpha, \beta, \gamma, \delta)$ of functions which are regular in the circular ring $K_z(q^2, 1)$, $q^2 < |z| < 1$, and which are representable by the structural formula

$$(*) \quad P(z) = 1 - \alpha - \beta + \frac{\alpha}{2\pi} \int_{-\pi}^{\pi} \frac{1 + ze^{-i(t-\gamma)}}{1 - ze^{-it}}\, d\mu_1(t) + \frac{\beta}{2\pi} \int_{-\pi}^{\pi} \frac{1 + (q^2/z)e^{i(t+\delta)}}{1 - (q^2/z)e^{it}}\, d\mu_2(t)$$

where $\alpha \geq 0$, $\beta \geq 0$, $0 < \alpha + \beta \leq 1$, $-\pi < \gamma, \delta < \pi$, $0 < q < |z| < 1$. The integral is a Stieltjes integral, and $\mu_1(t)$ and $\mu_2(t)$ are real nondecreasing functions of t in $[-\pi, \pi]$ with $\mu_j(-\pi) = \mu_j(-\pi + 0)$, $\mu_j(\pi) = 2\pi$, $j = 1, 2$, and $P(z)$ is normalized so that $(1/2\pi i) \int_{|z|=\rho} (P(z)/z)\, dz = 1$, $q^2 < \rho < 1$. By letting $q \to 0$, $\gamma = 0$, $\alpha = 1$, the class $C_q(\alpha, \beta, \gamma, \delta)$ is the well-known class P of functions with positive real part in the unit disk.

The author obtains sharp bounds for $|P(z)|$ and $\arg P(z)$ for functions belonging to $C_q(\alpha, \beta, \gamma, \delta)$. He shows that the Laurent coefficients satisfy $|a_n| \leq 2\alpha \cos(\gamma/2)$ and $|a_{-n}| \leq 2q^{-n}\beta \cos(\delta/2)$.

W. C. Royster (Lexington, Ky.)

Kocur, M. F. 6005
Some special classes of analytic functions in a circular annulus. II. (Russian)
Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 5 (42), 30–40.

Let $S_q(\alpha, \beta, \gamma, \delta)$ denote the class of functions $f(z)$ that are regular in the circular ring $K(q^2, 1)$ and satisfy the condition $zf'(z)/f(z) = P(z)$, where $P(z)$ belongs to $C_q(\alpha, \beta, \gamma, \delta)$ and is given by (*) in the preceding review [#6004]. We see by taking $\alpha = \beta$, $0 \leq \alpha \leq \frac{1}{2}$, $\gamma = \delta$, and letting $q \to 0$ that we get the class of spiral-like functions of order α in $|z| < 1$, and if $\gamma = 0$, then we have the starlike functions of order α in $|z| < 1$. For the class $S_q(\alpha, \beta, \gamma, \delta)$ the author obtains sharp bounds for $|f(z)|$ and $\arg f(z)$.

Let $g(z)$ be regular in $K_z(q^2, 1)$ and satisfy $P(z) = 1 + zg''(z)/g'(z)$. Bounds for $|g'(z)|$ and $\arg g'(z)$ are obtained. All of the expressions for these bounds are too long and cumbersome to be displayed.

W. C. Royster (Lexington, Ky.)

Ozawa, Mitsuru 6006
On certain coefficient inequalities of univalent functions.
Kōdai Math. Sem. Rep. **16** (1964), 183–188.

In this note the author solves two extremal problems by means of Schiffer's variational method [Proc. London Math. Soc. (2) **44** (1938), 432–449]. The author's purpose in introducing these problems is to show that the "perfect square" technique used by Charzyński and Schiffer in a consideration of the fourth coefficient in the Bieberbach conjecture [Arch. Rational Mech. Anal. **5** (1960), 187–193; MR **22** #5746] is not always applicable.

Let S denote the family of all functions $f(z) = z + \sum_2 A_n z^n$, which are analytic and univalent in the unit disc $D: [z| \; |z| < 1]$. Then the author obtains the following results. (I) In S the inequality

$$|A_4 - 3A_2A_3 + 2A_2^3| \leq 2$$

holds, with equality only for the Koebe function. (II) In S the inequality

$$\operatorname{Re}\left\{A_5 - 2A_2A_4 - \frac{3}{2}A_3^2 + 4A_2^2A_3 - \frac{79}{54}A_2^4\right\} \leq \frac{1}{2}$$

holds, with equality only for functions in S that satisfy the equation

$$\frac{1}{w^2}\sqrt{\left(1 + \frac{4}{3}A_2 w\right)^3} = \frac{1}{z^2} - \left(2A_3 - \frac{4}{3}A_2^2\right) - z^2.$$

M. Reade (Ann Arbor, Mich.)

Pommerenke, Christian 6007
Linear-invariante Familien analytischer Funktionen. I, II.
Math. Ann. **155** (1964), 108–154; *ibid.* **156** (1964), 226–262.

In this most interesting work, the author generalizes certain results from the theory of univalent functions to a wider class of analytic functions. He not only obtains generalizations of important old results, but also obtains certain new ones which should lead to further work in the area he has opened for investigation. In this brief review we can only give some of the author's results; the papers must be read to be fully appreciated.

Let D denote the unit disc $[z| \, |z| < 1]$, and let L denote the collection of linear fractional transformations that map D onto itself. Then a non-empty collection M of functions $f(z)$, analytic in D, is said to be a linear-invariant family if and only if (i) each $f(z)$ in M satisfies $f'(z) \neq 0$ in D, (ii) each $f(z)$ in M has the form $z + a_2 z^2 + \cdots$ in D, and (iii) for each $f(z)$ in M and for each ϕ in L, the function

$$\Lambda_\phi[f(z)] = \frac{f(\phi(z)) - f(\phi(0))}{\phi'(0) f'(\phi'(0))}$$

is again in M. A family M of functions $f(z)$, analytic in D, is said to be "beschränktartig" if and only if there exists a constant $K = K(M)$ such that

$$\int_0^{2\pi} \log^+ |f(re^{i\theta})| \, d\theta \leq K, \qquad z = re^{i\theta},$$

holds for $0 \leq r < 1$, for each $f(z)$ in M. The order of a linear invariant family M is defined to be $\alpha = \sup[\frac{1}{2}|f''(0)| \, |f(z)$ in $M]$. In Chapter 1, the author obtains results reminiscent of results on normal families and distortion theorems. For example, he proves that the linear-invariant family M is normal if and only if the order of M is finite. He also proves that the family of locally univalent, analytic functions $f(z) = z + a_2 z^2 + \cdots$, each of which is areally mean p-valent, is linear-invariant, beschränktartig, and hence normal. The author shows that if the order of a linear-invariant family M is α, then

$$|\log[(1 - |z|^2) f'(z)]| \leq \alpha \log \frac{1 + |z|}{1 - |z|},$$

from which it follows that the image of the closed disc $[z| \, |z| \leq r < 1]$ under $w = f(z)$ contains a disc of radius

$$\frac{1}{2\alpha}\left[1 - \left(\frac{1 - r}{1 + r}\right)^\alpha\right].$$

In Chapter 2, the author obtains other distortion theorems, which lead to the following results (among many others). (i) If M is a compact linear-invariant family of order α, and if $f(z)$ in M has the form $z + \alpha z^2 + a_3 z^3 + \cdots$, then $a_3 = \frac{2}{3}\alpha^2 + 1$. (ii) If M is a compact linear-invariant family of order α, then each $f(z)$ in M is convex and univalent in the disc $[z| \, |z| < \alpha - \sqrt{(\alpha^2 - 1)}]$; this result is sharp. (iii) Let M be a compact linear-invariant family of order α, let r_0 denote the largest real number for which $f(z)/z$ does not vanish for $[z| \, |z| < r_0]$, for any member of M, and let r_1 denote the "radius of univalence" of M. Then $r_1 = r_0/(1 + \sqrt{(1 - r_0^2)})$, and this result is sharp. In this same chapter, the author considers images of non-euclidean lines, the distance from a point to the boundary in the image domain, growth properties of the maximum modulus, and the notions of accessible points and prime ends. In Chapter 3, the author introduces the notion of "boundary behavior" for a linear-invariant family. Indeed, let M be a linear-invariant family that is also a normal family, and let $f(D)$ denote the image of the disc D under $w = f(z)$. Now set

$$f(ze^{i\theta}, \rho e^{i\theta}) = \frac{f\left(\dfrac{e^{i\theta}z + \rho e^{i\theta}}{1 + \rho z}\right) - f(\rho e^{i\theta})}{(1 - \rho^2) f'(\rho e^{i\theta})},$$

where z and $\rho e^{i\theta}$ are in D. Then $C(e^{i\theta}, f)$ is the set of all functions $g(z)$ for which there exists a sequence of real numbers $\rho_n \to (1 - 0)$ such that $e^{-i\theta} f(ze^{i\theta}, \rho_n e^{i\theta}) \to g(z)$ locally

uniformly in D, and $C(f)$ is the set of all functions for which there exists a sequence $\rho_n e^{i\varphi_n}$ with $\rho_n \to (1-0)$ such that $e^{-i\varphi_n} f(ze^{i\varphi_n}, \rho_n e^{i\varphi_n}) \to g(z)$. The sets $C(e^{i\varphi}, f)$ and $C(f)$ are those that indicate the "boundary behavior" of the family M; for the case that M is the set of all normalized univalent functions in D, $C(e^{i\varphi}, f)$ and $C(f)$ reduce to known items in the theory of univalent functions. For example, if $C(1, f)$ reduces to just one function $g(z)$, then the author shows that $g(z) \equiv (1/2c)[((1+z)/(1-z))^c - 1]$, where c is a complex constant. If M is a normal and linear-invariant family in D, and if $f(z) \in M$, then the author says $f(z)$ has "gut-erreichbares Verhalten" at $e^{i\varphi}$ if and only if there exists x_1, $0 < x_1 < 1$, so that

$$(1 - x_1^2)|g'(x_1)| < 1$$

holds for all $g(z) \in C(e^{i\varphi}, f)$. If this last inequality holds for all $g(z)$ in $C(f)$, then $f(z)$ has uniformly "gut-erreichbares Randverhalten". These last two notions lead to "angle limits" and the classical idea of accessible boundary points. A further result is a criterion as to when a univalent function (in D) can be extended to a quasiconformal map of the plane onto itself; this is connected with a recent result due to Ahlfors [Acta Math. **109** (1963), 291–301; MR **27** #4921]. After many more results, the author concludes with a discussion of the boundary behavior of M, yielding results that generalize a "Faltensatz" due to Ostrowski [Prace Mat.-Fiz. **44** (1937), 371–471].

Again, the present author's results may be looked on as generalizations of well-known results on univalent functions associated with the names of Bieberbach, Gronwall, Pick, Koebe, Visser, Lavrentieff, Ferrand, Walsh, Gehring, Hayman, Gaier, et al.

Some estimates in the theory of univalent conformal mappings of doubly connected domains. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1160–1163.

Let $H(R)$ be the class of functions regular and univalent in the annulus $R < |z| < 1$ which map it onto a domain situated inside the unit disc, with the outer boundary corresponding to $|z| = 1$. Let $H^*(R) \subset H(R)$ be the subclass of functions leaving $|z| = 1$ invariant. Some distortion theorems for both classes are proved.

Z. Lewandowski (Lublin)

Fuller, D. J. H. 6009

Mappings of bounded characteristic into arbitrary Riemann surfaces.

Pacific J. Math. **14** (1964), 895–915.

This paper treats value distribution theory for analytic mappings of an arbitrary open Riemann surface R into an arbitrary Riemann surface S. The proximity function is defined in terms of a principal function which has two logarithmic poles with opposite coefficients ± 1 and is normalized there by additive constants. The author obtains a generalization of Nevanlinna's first main theorem. The generalization of H. Cartan's theorem is given for the characteristic function whose proximity function is defined in terms of the principal function which satisfies the above condition and has constant value on ∂S. Let MB be the class of analytic mappings of R into S whose characteristic functions are bounded. Some characterizations of MB functions are given. The class MB is identical with the class of Lindelöfian maps.

Y. Kusunoki (Kyoto)

Sario, Leo 6010

General value distribution theory.

Nagoya Math. J. **23** (1963), 213–229.

The author considers analytic mappings from arbitrary Riemann surfaces into arbitrary Riemann surfaces. He generalizes the first and second fundamental theorems of Nevanlinna in a manner that is of interest even in the classical setting. He then derives an analogue of the classical relation concerning defective and ramified values. The author's "principal functions" are an important tool in constructing the necessary proximity functions.

The paper is the text of two lectures delivered by the author in May 1963 at Stanford. The style is somewhat more discursive than is usual in mathematical articles, and some details are omitted in order to emphasize the main aspects of the theory. The author has happily succeeded in his exposition, and the paper is recommended to any one who wishes to understand the author's recent contributions to general value distribution theory.

For complete details one is referred to the author's articles noted in the bibliography.

Notes on Green lines and Kuramochi boundary of a Green space.

J. Sci. Hiroshima Univ. Ser. A-I Math. **28** (1964), 59–66.

Let Ω be a Green space in the sense of Brelot and Choquet [Ann. Inst. Fourier (Grenoble) **3** (1951), 199–263; MR **16**, 34], and let Ω^* be a compactification of Ω. A statement is said to hold for almost all curves if the family of exceptional curves has infinite extremal length. Theorem: Almost every Green line converges to one point of $\Omega^* - \Omega$ provided either (i) there exists a countable family of BLD functions which separates the points of $\Omega^* - \Omega$, or (ii) Ω^* is metrizable and the set of BLD functions which extend continuously to Ω^* separates the points of $\Omega^* - \Omega$ (f separates $a, b \in \Omega$ if $\liminf_{\Omega \ni x \to a} f(x) > \limsup_{\Omega \ni x \to b} f(x)$). Corollary: On a hyperbolic Riemann surface almost every Green line tends to one point of the Kuramochi boundary.

An analogue of the Kuramochi boundary of a Riemann surface is defined for a general Green space. It is shown that this boundary shares with Kuramochi's boundary the above property of Green lines as well as several other properties.

★Quasikonforme Abbildungen.

Ergebnisse der Mathematik und ihrer Grenzgebiete. Neue Folge, Heft 26.

Springer-Verlag, Berlin-Göttingen-Heidelberg, 1960. viii+182*pp*. *DM* 39.00.

The author has assembled a remarkable amount of the research on quasiconformal mappings in a relatively short monograph; indeed, every major result up to 1960 is either described or referred to. It is natural that, in order to bring together so much material within a limited space, it was necessary for the author to sacrifice any hope of writing a self-contained monograph which might introduce the novice to the field: instead, the monograph, with its rich bibliography, is invaluable to the specialist in the field.

After a concise introductory chapter on conformal mapping, there follows a chapter on quasiconformal homeomorphisms à la Grötzsch, ending with the Teichmüller and Grötzsch extremal problems. Chapter 3 is brief, and is devoted to the classical applications of quasiconformal mappings in the theory of functions. Chapter 4 is concerned with general K-quasiconformal homeomorphisms, and Chapter 5 with K-quasiconformal mappings. Chapter 6 is devoted to quadratic differentials and extremal quasiconformal mappings, while Chapter 7 contains applications to differential equations and pseudo-analytic functions. *A. J. Akaza, Tohru 6015

Poincaré theta series and singular sets of Schottky groups.

Nagoya Math. J. **24** (1964), 43–65.

This is a study of the convergence of the Poincaré theta series and the Hausdorff dimension of the singular set of a Schottky group. The $(-\nu)$-dimensional theta series converges together with $\sum |c|^{-\nu}$ (the transformations of the group are $(az+b)(cz+d)^{-1}$). Less trivially, in case of convergence the singular set has $(\nu/2)$-dimensional measure zero. There are many other results that are consequences of geometric conditions relative to the circles that define the Schottky group. The author proves the existence of a singular set of Hausdorff dimension >1. Such a set is not a Painlevé null set. *L. V. Ahlfors* (Cambridge, Mass.)

A note on entire functions and a conjecture of Erdős. II.

J. Analyse Math. **12** (1964), 83–104.

As announced in their previous paper [Bull. Amer. Math. Soc. **69** (1963), 573–577; MR **26** #6409], the authors prove several inequalities relating U, u,

$$U^* = \limsup_{n\to\infty} (\mu(\rho_n)/M(\rho_n))$$

and

$$u^* = \liminf_{n\to\infty} (\mu(\rho_n)/M(\rho_n))$$

(for notations and terminology see their earlier paper). For example, for any entire function $U^* \leq 2/\pi$, $u^*=u$, and if $u<U$ every point of $[u, U]$ is a limit point of $\{\mu(r)/M(r)\}$. Several results on entire functions defined by gap power series are also established and finally, the conjecture of Erdős, which is proved not to hold for functions holomorphic in $|z|<R<\infty$, is modified for that type of function by the additional assumption that $\{\rho_n\}$ is an infinite sequence. If so, it is proved that if either

$$\limsup_{k\to\infty} (n_{k+1}-n_k) < \infty$$

or

$$\lim_{k\to\infty} [\rho(n_k)/\rho(n_{k+p})]^{n_{k+p}-n_{k+p-1}} = 1$$

for $p=1, 2, \cdots$, then $U=0$.

A. G. Azpeitia (Amherst, Mass.)

Hellerstein, S.; Korevaar, J. 6017

The real values of an entire function.

Bull. Amer. Math. Soc. **70** (1964), 608–610.

If $f(z)$ is a nonconstant entire function of order ρ and $\Phi(r)$ is the number of points of $|z|=r$ at which $f(z)$ is real, the authors show that

$$\kappa = \limsup \frac{\log \Phi(r)}{\log r} = \rho.$$

That $\kappa \geq \rho$ was shown by the reviewer [same Bull. **67** (1961), 488–489; MR **24** #A1398] by a more complicated method than that used here. In this paper, $\kappa \geq \rho$ depends on the elementary theory of Borel exceptional values, while $\kappa \leq \rho$ depends on Jensen's theorem applied to $\mathrm{Im}(f(re^{i\theta}))$ regarded as an entire function of θ.

[Reviewer's remark. The authors have pointed out that, before equation (10), it is not enough for $g_r(0) \neq 0$, but note that $|g_r(0)| \geq 1$ can be accomplished by a rotation, which is sufficient.] *H. S. Wilf* (Philadelphia, Pa.)

Rauzy, Gérard 6018

Fonctions entières prenant des valeurs entières sur des ensembles partiels d'entiers.

C. R. Acad. Sci. Paris **259** (1964), 19–21.

A sequence of natural numbers is said to have infinite frequency if it contains intervals (n, A^n) with arbitrarily large A. Pólya's theorem on integer-valued functions is generalized to the theorem that an entire function of exponential type $\sigma < \log 2$ which is integer-valued on a sequence of infinite frequency is a polynomial. The proof is reduced via the Borel transform to the following generalization of the Pólya-Carlson theorem: A function $f(z)=\sum a_n z^{-n}$, where the a_n are integers for a sequence of

indices of infinite frequency, is analytic for $|z-1| > \rho$ with $\rho < 1$ if and only if it is rational with no poles except at $z=1$.

Hayman, W. K. 6019

On the characteristic of functions meromorphic in the unit disk and of their integrals.

Acta Math. **112** (1964), 181–214.

It is known that the derivative of a bounded analytic function in a disk need not be of bounded Nevanlinna characteristic [Frostman, Kungl. Fysiogr. Sällsk. i Lund Förh. **12** (1942), 169–182; MR **6**, 262]. Precise information concerning the growth of the Nevanlinna characteristic function of the derivative of a function of bounded type has been obtained by P. B. Kennedy [Quart. J. Math. Oxford Ser. (2) **15** (1964), 337–341].

The converse question whether a function meromorphic in a disk can have an unbounded Nevanlinna characteristic function while its derivative is of bounded type is settled by the present paper. The following theorems are established. (I) Let f be meromorphic and of bounded type in $|z| < R$, $0 < R < +\infty$, $f(0) \neq \infty$. Then

$$(2\pi)^{-1}\int_0^{2\pi} \log^+ f_1(re^{i\theta})\,d\theta \le T(R,f) + \pi^{-1}\log\frac{R+r}{R-r}\,m(R,f) + \psi\left(\frac{r}{R}\right)N(R,f)$$

$$\le \left[1+\psi\left(\frac{r}{R}\right)\right]T(R,f)$$

for $0<r<R$, where

$$\psi(t) = \left[(1-t)\log\left(1+\frac{2\pi\sqrt{t}}{1-t}\right)\right](\pi\sqrt{t}\log t^{-1})^{-1},$$

$f_1(re^{i\theta}) = \sup_{0\le t\le r}|f(te^{i\theta})|$ and T, m, and N have the standard meanings in the Nevanlinna theory. The first part of the inequality is sharp when f is analytic. This theorem has a subharmonic counterpart. (II) Given F meromorphic in $|z| < R$, $F(0)=0$, $f=F'$ of bounded type in $|z|<R$, then

$$m(r,F) \le T(R,f) + \pi^{-1}\log\frac{R+r}{R-r}\,m(R,f) + \psi\left(\frac{r}{R}\right)N(R,f) + \log^+ r$$

$$\le \left[1+\psi\left(\frac{r}{R}\right)\right]T(R,f) + \log^+ r.$$

One has $T(r,F) \le [2+\psi(r/R)]T(R,f) + \log^+ r$, $0<r<R$, and if F is analytic,

$$T(r,F) \le \left(1+\frac{1}{\pi}\log\frac{R+r}{R-r}\right)T(R,f).$$

(III) Given $C>0$, there exists f analytic, $|f|>1$, in $|z|<1$, and satisfying $T(1,f)-\log|f(0)|=C$, while $T(r,F) > .12C\log[1/(1-r)]$, $r_0<r<1$, where $F(z)=\int_0^z f(\zeta)\,d\zeta$, $r_0 = 1-[\min(\frac{1}{2},C)]^4$, A being an absolute positive constant. Applications of these theorems to entire and meromorphic functions will be given in a later paper.

M. H. Heins (Urbana, Ill.)

Džrbašjan, M. M. 6020

The parametric representation of some general classes of meromorphic functions in the unit circle. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1024–1027.

For $\varphi \in L(0,1)$, $\alpha > 0$, define

$$D^{-\alpha}\varphi(r) = \frac{1}{\Gamma(\alpha)}\int_0^r (r-t)^{\alpha-1}\varphi(t)\,dt,$$

and extend the definition to α in the interval $(-1,0)$ by $dD^{-(1+\alpha)}\varphi(r)/dr = D^{-\alpha}\varphi(r)$. Write $g_+(r)$ for $\max(g(r),0)$. Let $F(z)$ be meromorphic in $|z|<1$, and write $n(t)$ for the number of its poles in $|z|\le t$. Put

$$N_\alpha(r,F) = r^{-\alpha}D^{-(1+\alpha)}\{[n(r)-n(0)]/r\} + n(0)\log r/\Gamma(1+\alpha).$$

Further, let

$$m_\alpha(r,F) = (r^{-\alpha}/2\pi)\int_0^{2\pi} D_+^{-\alpha}\log|F(re^{i\theta})|\,d\theta.$$

The function $T_\alpha(r,F) = m_\alpha(r,F) + N_\alpha(r,F)$ is called the α-characteristic of F. For $\alpha=0$ it is identical with the Nevanlinna characteristic. T_α is an increasing function of r. The class N_α of meromorphic functions contains those functions for which $T_\alpha(r,F)$ is $O(1)$ in $r<1$. The author has shown that $N_\alpha < N_\beta$ $(-1<\alpha<\beta)$. He proves $F\in N_\alpha$ if and only if

$$F(z) = K\frac{\pi_\alpha(z,a)}{\pi_\alpha(z,b)}\exp\left\{\int_0^{2\pi}(1-e^{-i\theta}z)^{-1-\alpha}\,d\psi(\theta)\right\},$$

where K is a constant, $\pi_\alpha(z,a)$ is an (explicitly defined) product analogous to a Blaschke product extended over the zeros of F, $\pi_\alpha(z,b)$ is the same type of product extended over the poles, and ψ is a function of bounded variation. For $\alpha=0$ this gives the well-known characterization of functions of bounded Nevanlinna characteristic.

W. H. J. Fuchs (Ithaca, N.Y.)

Džrbašjan, M. M. 6021

On the representation of certain classes of entire and quasi-entire functions. (Russian)

Dokl. Akad. Nauk SSSR **159** (1964), 9–12.

Let the z-plane be divided into sectors by a finite number of rays from the origin. Let $\arg z = \theta_1, \cdots, \theta_p$ be the middle lines of the largest sectors, each one of which has an angle π/ρ $(\rho \ge \frac{1}{2})$ at the origin. Let $W(\rho,\sigma)$ be the class of entire functions $f(z)$ of order ρ and finite type satisfying

$$(1) \qquad \int_0^\infty |f(z)|\,|z|^\omega|dz| < \infty$$

$(-1<\omega<1$, integration along any boundary of a sector) and

$$(2) \qquad \limsup_{r\to\infty}\log|f(re^{i\theta_k})|r^{-\rho} \le \sigma_k,$$

$$\sigma_k \ge 0 \quad (k=1,2,\cdots,p).$$

If $f(z)\in W(\rho,\sigma)$, then

$$f(z) = \sum_{k=1}^{p}\int_0^{\sigma_k} E_\rho(e^{-i\theta_k}zt^{1/\rho},\mu)\varphi_k(t)t^{\mu-1}\,dt$$

when $E_\rho(z,\mu) = \sum_{k=0}^\infty z^k/\Gamma(\mu+k\rho^{-1})$ and $\mu = (1+\omega+\rho)/2\rho$, $\varphi_k(t)\in L^2(0,\sigma_k)$. Vice versa, any such integral represents an entire function of class $W(\rho,\sigma)$. The functions φ_k can be written as integral transforms of $f(z)$, so that this

representation is a complete analogue of the Paley-Wiener theorem.

The paper also contains integral representations for "quasi-entire" functions, i.e., functions $f(z)$ analytic on the Riemann surface of $\log z$ and such that $f(z)$ tends to a limit as $z \to 0$ in any manner on this Riemann surface. The role of the function $E_\rho(z, \mu)$ is now taken over by $\int_0^\infty z^t/\Gamma(\mu + t\rho^{-1})\,dt$. *W. H. J. Fuchs* (Ithaca, N.Y.)

Collingwood, E. F.; Piranian, G. 6022

The mapping theorems of Carathéodory and Lindelöf.

J. Math. Pures Appl. (9) **43** (1964), 187–199.

Let B be a bounded simply connected plane region, and let D be the open unit disk. A sequence $\{c_n\}$ of cross-cuts of B is called a "weak" chain, provided that, for all positive integers n and k, (i) c_n separates c_{n+k} with respect to B from some fixed point of B; (ii′) rel dist $(c_n, c_{n+k}) > 0$ (rel dist is the infimum of diameters of arcs in B connecting c_n to c_{n+k}); and (iii) no closed subset of B meets every c_n. This modifies Carathéodory's notion of a chain of cross-cuts (here called a "C-chain") which required, in place of (ii′), the condition (ii) $\bar{c}_n \cap \bar{c}_{n+k} = \varnothing$ [Math. Ann. **73** (1913), 323–370]. Carathéodory's theorem is then proved by the authors in the form: Any conformal homeomorphism $B^* \to D$ can be extended to a homeomorphism $B^* \to \bar{D}$, where B^* is the compactification of B by means of "weak" prime ends. The latter are defined in terms of "weak" chains of cross-cuts, in precisely the same way Carathéodory used to obtain prime ends from his C-chains of cross-cuts. It is shown that every Carathéodory prime end is a "weak" prime end, and conversely. However, the proof of the mapping theorem is now more direct and perspicuous than in Carathéodory's version. The authors' argument rests on a length-area comparison by means of the Schwarz inequality.

In the last two sections, the theorem of Lindelöf [Acta Soc. Sci. Fenn. **46** (1915), no. 4] that the principal cluster set coincides with the cluster set along a Stolz path is proved by a similar method. It is here given in a setting due to Gross, under the hypothesis that the meromorphic function f with domain D maps some neighborhood (relative to D) of a boundary point onto a Riemann surface of finite spherical area.

E. C. Schlesinger (New London, Conn.)

Matsumoto, Kikuji 6023

Some notes on exceptional values of meromorphic functions.

Nagoya Math. J. **22** (1963), 189–201.

It was shown by the author [same J. **18** (1961), 171–191; MR **24** #A237] that, given any closed set K of capacity zero, there exists a closed set E of capacity zero and a function $f(z)$ meromorphic in the complement of E which possesses an essential singularity at each point of E and omits the set K. On the other hand, L. Carleson [Bull. Amer. Math. Soc. **67** (1961), 142–144; MR **24** #A238] established the existence of a linear closed set F of positive capacity such that every function $f(z)$ meromorphic in the complement of F and omitting four values there is rational. Carleson's set F is a Cantor set on $[0, 1]$, where the successive ratios ξ_ν decrease and satisfy the relation $\lim \log \xi_\nu/\log \nu = -\infty$. As a consequence of a more general theorem, too complicated to be stated here, the author shows that if F is a Cantor set on $[0, 1]$, where the successive ratios ξ_ν merely satisfy the condition $\lim \xi_\nu = 0$, then every function, meromorphic in the complement Ω of F, which has at least one essential singularity in F, omits at most three values in that subset of Ω which lies in some neighborhood of each essential singularity. Other interesting generalizations of Picard's theorem of this general character are obtained.

W. Seidel (Detroit, Mich.)

Vituškin, A. G. 6024

On a problem of Denjoy. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 745–756.

The following problem is considered. Determine a set e in the finite complex plane and a function $f(z)$ with the properties: (i) e is compact and totally disconnected, (ii) e has vanishing φ-Hausdorff measure, where $\varphi(\delta)$ is a given monotone function with $\varphi(\delta)/\delta \to 0$ for $\delta \to 0$, (iii) $f(z)$ is continuous in the finite plane, non-constant, and analytic outside e, (iv) $\int_\gamma f\,dz = 0$ for any contour γ disjoint to e.

The author gives an example for the solution (the reviewer was unable to follow the actual construction), notes the connection with Morera's theorem, and observes that the function $f(z)$ cannot be represented as a Golubev series $\sum_{k=0}^\infty \int_e (\zeta - z)^{-1}\,d\mu_k(\zeta)$. A related example shows finally that the integral of a small analytic function around a set of small analytic capacity need not be small.

F. Huckemann (E. Lansing, Mich.)

Aronszajn, N.; Donoghue, W. F. 6025

A supplement to the paper on exponential representations of analytic functions in the upper half-plane with positive imaginary part.

J. Analyse Math. **12** (1964), 113–127.

If $\varphi(\zeta)$ is analytic and has positive imaginary part in the upper half-plane, it may be represented in the form

$$\varphi(\zeta) = \alpha\zeta + \beta + \int_{-\infty}^{\infty} \left[\frac{1}{x-\zeta} - \frac{x}{x^2+1}\right] d\mu(x),$$

where $d\mu$ is a positive measure. Moreover, $\log \varphi(\zeta)$ (principal branch) has such a representation with $\alpha = 0$ and $d\mu(x) = f(x)\,dx$, $0 \le f(x) \le 1$. This leads to the "exponential representation" of $\varphi(\zeta)$. In an earlier paper [same J. **5** (1956/57), 321–388] the authors found various close connections between the growths of $d\mu(x)$ and $f(x)$ near $x = \infty$. These results are now extended to finer measurements of growth, the proofs are simplified, and a few oversights in the earlier paper are corrected.

P. L. Duren (London)

Curtiss, J. H. 6026

Harmonic interpolation in Fejér points with the Faber polynomials as a basis.

Math. Z. **86** (1964), 75–92.

Let $[a_{i,j}]_n$ represent a determinant of order n with $a_{i,j}$ the element in the ith row and jth column. There are $2n+1$ linearly independent harmonic polynomials of degree n. Let $\{h_k(z)\}$ denote a particular basis. A collection of $2n+1$ points is called a rank set of degree $2n+1$ if and only if $[h_i(z_j)]_{2n+1} \neq 0$. If $\{z_i\}$ is a rank set of degree $2n+1$, then

there exists a harmonic polynomial of degree n taking on arbitrarily preassigned values at the $\{z_i\}$.

Let C be an analytic curve. The normalized exterior mapping function maps C onto a circle Σ. For each integer n there is a unique set of $2n+1$ points on C determined as the images of $2n+1$ equally spaced points on Σ, where one point on Σ lies on the positive x-axis. Call this set the Fejér set F_n.

The author shows: (a) If C is a star-shaped curve, then F_n is a rank set for all n sufficiently large (say $n > n_0$); (b) If C is star-shaped and $g(z)$ is a continuous function on C, then if $H_n(z)$, a harmonic polynomial of degree n, interpolates $g(z)$ on F_n, the $H_n(z)$ converge uniformly on closed sets of the interior of C to the harmonic function having $g(z)$ as boundary values.

In the proof of (b) $\{h_n(z)\}$ are chosen as the real and imaginary parts of the Faber polynomials associated with C. The technique for showing $[h_i(z_j)]_{2n+1} \neq 0$ is to multiply by a non-singular determinant to obtain a determinant with a dominant principal diagonal for large n.

For a general analytic curve and $n \leq 4$, it is known that F_n need not be a rank set [Sobczyk, J. Soc. Indust. Appl. Math. **12** (1964), 499–514]. Information for the case $n > 4$ would thus seem to be of interest. The assumption of star-shapedness plays an essential role in the author's method, so new methods would apparently be needed.

J. L. Ullman (Ann Arbor, Mich.)

Ibragimov, G. I. 6027

On the completeness of subsystems of Faber polynomials on curves in the complex plane. (Russian)

Mat. Sb. (*N.S.*) **65 (107)** (1964), 3–17.

If $w = \Phi(z) = z + a_0 + a_1 z^{-1} + \cdots$ maps the outside of the simple closed curve L onto $|w| > \rho$, then the polynomial obtained by deleting the terms with negative powers of z in the expansion of $(\Phi(z))^n$ is called the nth Faber polynomial $\Phi_n(z)$ associated with z.

The author investigates the completeness of sets of Faber polynomials $\{\Phi_{\lambda_n}(z)\}$ in a Banach space of continuous functions defined on a system of curves C and with norm $\|f\| = \sup_{z\in C} e^{-p(|z|)} |f(z)|$. He also investigates the same problem for a Hilbert space with norm given by $\|f\|^2 = \int_C e^{-p(|z|)} |f(z)|^2 |dz|$. The weight function $p(t)$ is real-valued, and for $t > t_0$, $p(t) = \int_a^t y^{-1} q(y)\, dy$, where $q(y)$ tends monotonically to ∞ as $y \to \infty$. The system of curves C divides the plane into n domains $G_1, \cdots, G_n$. The domain G_j contains an angle $\gamma_j \leq \arg|z - z_j| \leq \gamma_j + (\pi/\alpha_j)$. In addition, C satisfies a smoothness condition. The curve L lies in one of the G_j (G_1, say), and special conditions have to be made about the width of G_1. A sufficient condition for completeness is then obtained under the condition that the sequence $\{\mu_n\} = \{n\} - \{\lambda_n\}$ satisfies $n/\mu_n \to \tau < 1$ as $n \to \infty$. The exact statement is too long to reproduce.

W. H. J. Fuchs (Ithaca, N.Y.)

Pommerenke, Ch. 6028

Über die Faberschen Polynome schlichter Funktionen.

Math. Z. **85** (1964), 197–208.

For $f(z) = z + a_0 + a_1 z^{-1} + \cdots$,

$$f'(z)/(f(z) - w) = \sum_0^\infty F_n(w) z^{-n-1}$$

is the generating function of the Faber polynomials $F_n(w) = w^n + b_n w^{n-1} + \cdots$. Let

$$F_n(f(z)) = z^n + n \sum_1^\infty a_{nk} z^{-k}.$$

The author proves the following for the case that $f(z)$ is schlicht for $|z| > 1$, and where E is the complement of the image of $|z| > 1$: (a) $\sum_1^\infty n \left|\sum_1^\infty a_{nk} c_k\right|^2 \leq \sum_1^\infty |c_k|^2/k$, c_k arbitrary; (b) $\log n < \max \sum_1^n |F_k(w)|/k < 4 \log n + 8$, the maximum being taken with respect to $w \in E$. The Grunsky inequality $\left|\sum_1^m \sum_1^m a_{jk} c_j c_k\right| \leq \sum_1^m |c_k|^2/k$ follows from (a). Refinements of (b) are made for the case when E is convex. Both (b) and its refinements are applied to the theory of transfinite diameter.

Suetin, P. K. 6029

The basic properties of Faber polynomials. (Russian)

Uspehi Mat. Nauk **19** (1964), *no.* 4 (118), 125–154.

Nach einer ausführlichen Besprechung der vorhandenen Literatur über die speziellen und die verallgemeinerten Faberpolynome werden die letzteren einer eingehenden Betrachtung unterzogen. Ist $B_n(z)$ das n-te Faberpolynom für den Bereich G bei der Belegung $g(z)$, so werden in § 1 unter bestimmten Bedingungen Abschätzungen von $|B_n(z)|$ in G vorgenommen; in § 2 folgt eine asymptotische Formel für $B_n(z)$. Die §§ 3 und 4 enthalten hinreichende Bedingungen für die absolute und gleichmäßige Konvergenz von Faberreihen in G bzw. in $\bar{G}$, darauf § 5 solche für die eindeutige Darstellbarkeit einer analytischen Funktion durch die zugehörige Faberreihe. In § 7 werden die Nullstellen der Faberpolynome als Interpolationsknoten verwendet. Sodann behandelt § 8 den Fall, daß die Belegung $g(z)$ lokale Nullstellen besitzt, und § 9 den Spezialfall, in welchem die Faberpolynome mit denen von Tchebychev übereinstimmen. Schließlich enthält § 10 noch erläuternde Bemerkungen und Desiderata.

K. Bögel (Ilmenau)

Gromov, V. P. 6030

The completeness of systems of derivatives of an analytic function. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **25** (1961), 543–556.

The generalized derivative $D^n F$ of a function $F(z) = \sum b_n z^n$ which is regular in $|z| < R$ is defined by

$$D^n F(z) = \sum_{k=0}^\infty b_{k+n} \left(\frac{a_k}{a_{k+n}}\right) z^k,$$

where $\sum_0^\infty a_k z^k = f(z)$ and f is of order ρ, type $\sigma \neq 0$, and such that $a_n \neq 0$ and $\lim n^{1/\rho} |a_n|^{1/n} = (\sigma e \rho)^{1/\rho}$. The author investigates the completeness of systems $\{D^{n_\nu} F(z)\}$. A necessary and sufficient condition for completeness in $|z| < R$ is that $F(z)$ satisfies no linear differential equation with constant coefficients $\sum a_n D^n F(z) = \Phi(z)$ whose characteristic function $\varphi(z) = \sum a_n z^n$ is of growth at most order ρ, type less than $R^\rho \sigma$, where Φ is regular at the origin with $\Phi^{(n_\nu)}(0) = 0$. If completeness is considered in a simply connected region D, the condition is that $f(z)$ satisfies no equation of the form

$$\int_\gamma f(\xi + z) g(\xi)\, d\xi = \Phi(z),$$

where γ is a closed contour in D, $g(\xi) \neq 0$ is analytic on

and outside γ, and $g(\infty)=0$, and Φ is as before. As applications of the first theorem, the author shows that if F is entire, then $\{D^n F(z)\}$ is complete in the finite plane if $F(z)$ is of growth at most order ρ, type 0, not a polynomial, or if $F(z)$ is of order ρ, finite type, and not a finite linear combination of the functions $z^k f^{(k)}(\lambda z)$; that if $F(z)=z^{-1}\int_0^z f(t)\,dt$, the system $\{D^{n_\nu}F(z)\}$ is complete provided $\lim \nu/n_\nu>0$; and that if $F(z)=e^{h(z)}$, where $h(z)$ is a polynomial of degree at least 2, then the system of ordinary derivatives $F^{(n)}(z)$ is complete in the plane. An application of the second theorem is that if the periodic function $\varphi(z)=\sum_{-\infty}^{\infty} c_k e^{ikz}$ is analytic in the strip $\alpha<\Im(z)<\beta$ then the system $\{\varphi^{(n)}(z)\}$ is complete in the rectangle $|\Re(z)|<\pi\tau$, $\alpha<\Im(z)<\beta$, provided $c_k\neq 0$ for $k=\mu_n$ with $\lim n/\mu_n=\tau\neq 0$. For related but independent work see Kaz'min [Vestnik Moskov. Univ. Ser. I Mat. Meh. **1960**, no. 5, 3–13; ibid. **1960**, no. 6, 11–19; MR **23** #A3268].

R. P. Boas, Jr. (Evanston, Ill.)

Korevaar, Jacob 6031

Asymptotically neutral distributions of electrons and polynomial approximation.

Ann. of Math. (2) **80** (1964), 403–410.

Let D be a bounded simply connected region; the author solves the problem of determining all bounded sets Γ such that every zero-free holomorphic function in D can be approximated, uniformly on compact subsets, by polynomials whose zeros lie in Γ. The solution depends on the notion of asymptotically neutral families, which are families of finite sequences $\{z_{nk}\}_1^n$ of points of Γ such that $\sum_{k=1}^n (z_{nk}-z)^{-1}\to 0$ uniformly on compact subsets of D; in other words, the electrostatic field at z of point charges at the z_{nk} tends to zero uniformly on compact subsets of D. The solution is as follows. Let Γ be bounded and disjoint from D. The following four statements are equivalent. (i) Γ possesses the approximation property of the problem. (ii) Γ possesses the approximation property relative to $1/(\zeta-z)$ for some one $\zeta\in\Gamma$. (iii) Γ contains an asymptotically neutral family relative to D. (iv) The closure of Γ divides the plane and D belongs to a bounded component of its complement. In particular, the boundary of D can always serve as Γ.

Dračinskiĭ, A. È. 6032

On a Riemann-Privalov boundary-value problem for the circle. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **34** (1964), 31–35.

The author states several results concerning boundary-value problems for the unit disc, of which the following is typical: To find a function $f(z)=u+iv$ analytic for $|z|<1$, representable by a Cauchy integral, and such that $au-bv=c$ almost everywhere on $|z|=1$, where a, b, c are real functions defined on $|z|=1$. Sufficient conditions are given for the existence of a solution and for uniqueness, and an explicit formula for the solution is given.

W. Kaplan (Ann Arbor, Mich.)

Kuz'mina, A. L. 6033

The Hilbert boundary-value problem with arbitrary shift. (Russian)

Comment. Math. Univ. Carolinae **5** (1964), 117–120.

Let L be a simple, closed Liapunov curve enclosing a domain D. Let $\omega(t)$, $t\in L$, be a continuous function with non-vanishing derivative which maps L into itself biuniquely with preservation of direction. The Hilbert problem, wherein one seeks a function $\phi(z)=u+iv$, analytic in D and continuous in $\bar D$, satisfying on L the relation (*) $a(t)u(\omega(t))+b(t)v(t)=c(t)$, where a, b, c are given real functions, is considered. The author shows that when $a(t)\neq 0$, $b(t)$, $c(t)$ belong to the space C_α of functions $f(t)$, $t\in L$, where $f(t)$ is Hölder-continuous with exponent α, $0<\alpha\leq 1$, and the norm is given by

$$C_\alpha(f)=\max_{t\in L}|f(t)|+\sup_{t,t_0\in L}|f(t)-f(t_0)|/|t-t_0|^\alpha,$$

then (*) will have a solution belonging to C_α depending on a real arbitrary constant if $C_\alpha(b/a)$ is less than a specified constant whose value depends on the function ω. As an application of this result, the author cites a boundary-value problem for the equation of mixed type:

$$u_{xx}+\operatorname{sgn} y\,u_{yy}=0.$$

J. F. Heyda (King of Prussia, Pa.)

Mihaĭlov, L. G. 6034

The general conjugacy problem for analytic functions and its applications. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **27** (1963), 969–992.

Let Γ consist of the simple closed Liapunov contours $\Gamma_0,\Gamma_1,\cdots,\Gamma_m$ which enclose the domain D^+, and denote the planar complement of $D^++\Gamma$ by D^-. The author considers the problem of determining functions $\varphi^+(z)$, $\varphi^-(z)$, analytic in D^+, D^-, respectively, representable by Cauchy integrals, whose boundary values $\varphi^+(t)$, $\varphi^-(t)$ satisfy on Γ the relation

$$(*)\quad \varphi^+(t)=a(t)\varphi^-(t)+b(t)\overline{\varphi^-(t)}+c(t),\qquad \varphi^-(\infty)=0,$$

where a, b, c are given functions.

The author presents a systematic study of this problem when $a(t)\neq 0$ on Γ and $|a(t)|>|b(t)|$ (elliptic case), and also when $|a(t)|=|b(t)|$ (parabolic case). No such study for the hyperbolic case ($|a(t)|<|b(t)|$) exists, although partial results are available [see, e.g., I. H. Sabitov, Sibirsk. Mat. Ž. **5** (1964), 124–129; MR **28** #3164].

Sur un problème non linéaire et discontinu de Hilbert-Haseman.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 287–292.

Let L be a smooth Jordan curve in the plane and $c_1, \cdots, c_p$ distinguished points on L; let α be a smooth transformation of L onto itself which leaves the c_s fixed. It is desired to find functions $\Phi_i(z)$ $(i=1, \cdots, n)$ analytic in the complement of L and whose limiting values $\Phi_i^{\pm}(t)$ on L satisfy the system of equations

$$\Phi_k^+[\alpha(t)] = \sum_{i=1}^{n} G_{ki}(t)\Phi_i^-(t) + F_k\{t, \Phi_1^+[\alpha(t)], \Phi_1^+(t), \cdots, \Phi_n^-[\alpha(t)], \Phi_n^-(t)\}.$$

The G_{ki} satisfy Hölder conditions on L; the F_k as functions of t have singularities at worst of a prescribed type at the c_s and as functions of their other arguments satisfy Hölder conditions. (The exact conditions are too complicated to state here.) The $\Phi_k(z)$ are to have singularities at the c_s at worst of a prescribed type. It is shown that this problem is equivalent to the solution of a certain nonlinear integral equation, which in turn is shown, by using the Schauder fixed-point theorem, to have at least one solution if certain constants involved in the conditions on the F_k are sufficiently small.

Gegelia, T. G. 6038

Behavior of a generalized potential near the boundary of the region of integration. (Russian)

Akad. Nauk Gruzin. SSR Trudy Tbiliss. Mat. Inst. Razmadze **26** (1959), 189–193.

In an earlier paper [Soobšč. Akad. Nauk Gruzin. SSR **18** (1957), 257–264; MR **20** #4710], the terminology of which is assumed here, it was shown that the integral

$$(1) \qquad \Phi(R) = \int_S \frac{M(Q, R)}{r^n(Q, R)} \varphi(Q)\, dS_Q$$

possesses angular boundary values at almost all points of the manifold S under certain restrictions on $M(Q, R)$ and on S. In the present paper the author establishes the rate at which the function $\Phi(R)$ tends to infinity as $R \to P \in S$ from a neighborhood $G(P, \varepsilon)$ of an arbitrary point P of S, including the boundary L of the manifold S. Theorem: If $\varphi(Q) \in L_p(S, r^\alpha(Q, P))$, $p \geq 1$, $-n < \alpha < n(p-1)$, and $P \in S$, then

$$|\Phi(R)| \leq C_{\varepsilon,\alpha,p,n} \|Q\|_p [r(R, P)]^{-(\alpha+n)/p}$$

for $R \in G(P, \varepsilon)$.

Dolženko, E. P. 6039

On the representation of continuous harmonic functions in the form of potentials. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 1113–1130.

Let u be a differentiable function in an open set dom $u \subset E_n$ and, for $M \subset$ dom u, denote by $\omega(\delta, M)$ and $\omega_i(\delta, M)$ the moduli of continuity on M of u and $\partial u/\partial x_i$, respectively. Let $f(\delta)$ be non-decreasing in $\delta \geq 0$, positive for $\delta > 0$, and denote by H_φ the Hausdorff measure determined by $\varphi(\delta) = \delta^{n-1}f(\delta)$. Suppose that G is a domain in E_n and E is a subset in G such that $G-E$ is dense in G and the inner measure (H_φ) of E is finite. Let dom $u \supset G-E$ and u be harmonic in an open set containing $G-E$. If $\omega(\delta, G-E) \leq f(\delta)$ and $\max_i \omega_i(\delta, G-E) \leq f(\delta)$, then there is a v, harmonic in G, a closed $F \subset E$, and bounded Borel measurable functions λ, μ_i on F such that, for $x \in G-E$,

$$(1) \quad u(x) = v(x) + \int_F \lambda(y) p_n(|x-y|) H_\varphi(dy) + \sum_i \int_F \mu_i(y) \frac{\partial p_n(|x-y|)}{\partial x_i} H_\varphi(dy),$$

where $p_n(r) = r^{2-n}$ or $p_n(r) = \log r$ according as $n > 2$ or $n = 2$. If dom $u \supset G$, $H_\varphi(E) < \infty$ and $\max_i \omega_i(\delta, G) \leq f(\delta)$, then (1) holds for $x \in G-F$ with all $\mu_i \equiv 0$. Hence some corollaries are derived; in particular, under the above assumptions, the singular set E is removable for the harmonic function u provided $H_\varphi(E) = 0$.

J. Král (Prague)

Kreyszig, Erwin 6040

Kanonische Integraloperatoren zur Erzeugung harmonischer Funktionen von vier Veränderlichen.

Arch. Math. **14** (1963), 193–203.

If $f(u, v, w)$ is complex-analytic in u and continuous for complex v and w, the operator

$$P[f](\mathbf{x}) = -\frac{1}{4\pi^2} \iint f(u, v, w) v^{-1} w^{-1}\, dv dw,$$

integrated over $|v| = 1$, $|w| = 1$, sends f into a harmonic function $P[f]$ of the vector $\mathbf{x} = (x_1, x_2, x_3, x_4)$ provided $u = \mathbf{a} \cdot \mathbf{x}$, where $\mathbf{a}(v, w)$ is a vector function satisfying $\mathbf{a} \cdot \mathbf{a} = 0$. Operators of the above type in R^3 have been studied by S. Bergman [*Integral operators in the theory of linear partial differential equations*, Springer, Berlin, 1961; MR **25** #5277]. The author proves that, with suitable choices for f and fixed $\mathbf{a}$, P generates a family of harmonic polynomials $\{H\}$ expressible in terms of Jacobi polynomials, that the H's are orthogonal on the unit sphere in R^4, and that any function harmonic in a neighborhood of the origin can be represented by a series in the H's. He also gives an integral formula for recovering f from the corresponding H.

R. E. Williamson (Norwich, Vt.)

Murdoch, B. H. 6041

A theorem on harmonic functions.

J. London Math. Soc. **39** (1964), 581–588.

The main theorem is to the effect that if $P(x)$, $x = (x_1, \cdots, x_k)$, is a homogeneous harmonic multinomial and $f(x)$ is a function harmonic everywhere in E_k such that $P(x)f(x) \geq 0$, all $x \in E_k$, then $f(x) = CP(x)$, where C is a constant ≥ 0. The proof is based on Fourier expansions in spherical harmonics, and on the following results: If $P(x)$ (as above) is of degree n and $R(x)$ is a homogeneous multinomial of degree m such that $P(x)R(x) \geq 0$, all x, then $m \geq n$; a harmonic multinomial is always "well-signed" in the sense that the factors in its factorization into a product of irreducible multinomials are distinct and each takes on both positive and negative values; if $P(x)$ and $Q(x)$ are well-signed multinomials such that $P(x)Q(x) \geq 0$ for all $x \in E_k$, then $Q(x) = CP(x)$, C a constant ≥ 0.

On Feller's kernel and the Dirichlet norm.

Nagoya Math. J. **24** (1964), 167–175.

The author first considers Brownian motion on a Green space (he assumes, without so noting, that the rigid motions are the local parameter transformations for all dimensions). He defines the analogue of a kernel used by Feller [Ann. of Math. (2) **65** (1957), 527–570; MR **19**, 892] and shows that it is a constant multiple of Naïm's [Ann. Inst. Fourier (Grenoble) **7** (1957), 183–281; MR **20** #6608] θ kernel, under slight restrictions on the Martin boundary of R. He then considers a diffusion on a bounded smooth domain of N-space, with infinitesimal operator a smooth self-adjoint differential operator A. Defining a version U of the Feller kernel for this operator he follows the method of the reviewer [ibid. **12** (1962), 573–621] to obtain a generalized Dirichlet integral of a sufficiently smooth solution of the first boundary-value problem for A in terms of U and the boundary function.

Harmonic functions in four variables with rational and algebraic p_4-associates.

Ann. Polon. Math. **15** (1964), 273–287.

Author's summary: "Integral representations for harmonic functions in four variables are investigated by means of an operator bearing close resemblance to the Whittaker-Bergman operator. The case where the p_4-associate is algebraic is considered by means of the theory of double integrals on algebraic three-folds. When the p_4-associate is rational, one obtains particularly interesting representations by considering the connections with Weierstrass integrals of the first, second, and third kinds defined over a Riemann surface. In addition, a residue theorem is given for a class of harmonic vectors $U=(u_1, u_2, u_3, u_4)$ satisfying the relations

$$\varepsilon_{mnrs}\frac{\partial u_r}{\partial x_s}=0, \qquad \frac{\partial u_\nu}{\partial x_\nu}=0,$$

which are analogous to the vanishing of the curl and divergence in three dimensions."

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 451–454.

Denote by $W^{(p)}LM$ the class of functions $f(\varphi)$ which are of period 2π, have an absolutely continuous $(p-1)$st derivative $(p\geq 1)$, and whose pth derivative satisfies $\int_0^{2\pi}|f^{(p)}(\varphi)|\,d\varphi\leq M=\text{const}$. If, instead of the latter inequality, we have $|f^{(p)}(\varphi)|\leq M$ almost everywhere, we denote the class of functions by $W^{(p)}M$. Consider functions $f(r, \varphi)$ which are biharmonic in the unit circle, assume values $f(\varphi)$ on $r=1$ and for which also $\partial f(r, \varphi)/\partial r|_{r=1}=0$. In a previous paper [Dokl. Akad. Nauk SSSR **153** (1963), 995–998; MR **28** #240] the author evaluated

$$\sup\max_{0\leq\varphi\leq 2\pi}|f(r, \varphi)-f(1, \varphi)|$$

for $f\in W^{(p)}M$. In the present paper he shows that one obtains the same upper bound if one considers $f\in W^{(p)}LM$.

★Theory of analytic functions of several complex variables.

Translated by A. A. Brown, J. M. Danskin and E. Hewitt.

American Mathematical Society, Providence, R.I., 1963. vi + 374 *pp.* $13.00.

This is a translation of the Russian book *Introduction to the theory of analytic functions of several complex variables* [Fizmatgiz, Moscow, 1962; MR **27** #4945]. A more modern version [*Special chapters in the theory of analytic functions of several complex variables* (Russian), Fizmatgiz, Moscow, 1963] has recently appeared.

Michiwaki, Yoshimasa 6050

Remarks on the minimum problems of several complex variables.

Res. Rep. Nagaoka Tech. College **1**, 145–150 (1963).

The paper asserts a formula for mappings between domains in several complex variables. However, it is very difficult to make out the proof, or even the meaning of the formula. *S. Bochner* (Princeton, N.J.)

Ibragimov, I. I. 6051

Inequalities for entire functions of finite degree in the metric of a generalized Lebesgue space. (Russian. Azerbaijani summary)

Akad. Nauk Azerbaidžan. SSR Dokl. **20** (1964), *no.* 4, 13–18.

The author compares different norms of an entire function of exponential type in n variables, where the function has finite $(p_1, \cdots, p_n)$ norm on the real hyperaxis (norm defined as in Dokl. Akad. Nauk SSSR **152** (1963), 1054–1057 [MR **27** #4949]). He gives bounds for the supremum in terms of the $(p_1, \cdots, p_n)$ norm; for the $(p_1, \cdots, p_k)$ norm in terms of the $(p_1, \cdots, p_m)$ norm, $1 \leq k < m \leq n$; and for the $(q_1, \cdots, q_n)$ norm in terms of the $(p_1, \cdots, p_n)$ norm, with $p_k < q_k$. *R. P. Boas, Jr.* (Evanston, Ill.)

Mamedhanov, D. I. 6052

Inequalities for positive entire functions in a generalized Lebesgue space. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 526–528.

The author continues the work of Ibragimov [#6051]. He obtains bounds for the $(q_1, \cdots, q_n)$ norm of $f(x+iy)$ in terms of the $(p_1, \cdots, p_n)$ norm of $f(x)$. He also obtains the analogous bounds for the classes of functions that satisfy $|f(x+iy)| \leq |f(x-iy)|$, $y \geq 0$, or are non-negative on the real hyperaxis. *R. P. Boas, Jr.* (Evanston, Ill.)

Disuguaglianze di Carleman sopra una varietà complessa.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **35** (1963), 431–434.

In this paper the authors announce certain results presented at the Centro Internazionale Matematico Estivo in July, 1963. By establishing certain inequalities of the type of Carleman [Ark. Mat. Astronom. Fys. **26B** (1939), no. 17; MR **1**, 55] the authors refine the finiteness theorems [Andreotti and Grauert, Bull. Soc. Math. France **90** (1962), 193–259; MR **27** #343] for the cohomology of locally free sheaves on q-concave or q-convex complex manifolds.

In particular the following theorem is stated. Let X be a q-complete complex manifold, and F a locally free sheaf on X. Then the cohomology groups $H_k^s(X, F)$ with compact support vanish for $s \leqq n-q$. $H_k^{n-q+1}(X, F)$ has a Hausdorff topology (i.e., the mapping $\bar\partial$ on $n-q$ forms of compact support has closed range). The finiteness theorems above follow from this by dualization and the use of the theorem of L. Schwartz [C. R. Acad. Sci. Paris **236** (1953), 2472–2473; MR **15** 233] on the Čech cohomology groups of a suitable covering. *H. Rossi* (Waltham, Mass.)

Grauert, Hans 6054

Bemerkenswerte pseudokonvexe Mannigfaltigkeiten.

Math. Z. **81** (1963), 377–391.

In einer früheren Arbeit [Ann. of Math. (2) **68** (1958), 460–472; MR **20** #5299] zeigte der Autor, dass in einer komplexen Mannigfaltigkeit X ein Gebiet $G \Subset X$ mit glattem Rand ∂G holomorph-konvex ist, wenn ∂G streng pseudokonvex ist. In der vorliegenden Arbeit wird durch ein Beispiel $T \Subset F$ zunächst gezeigt, dass dabei streng pseudokonvex nicht durch pseudokonvex ersetzt werden darf, selbst wenn G ein Meromorphiegebiet ist: Es sei R eine kompakte Kählersche Mannigfaltigkeit und F ein komplex analytisches Geradenbündel über R, das topologisch trivial sei. Es wird gezeigt, dass bereits eine geeignete Tensorpotenz F^k von F analytisch trivial ist, wenn in einer Umgebung der Nullschnittfläche von F eine nicht lokalkonstante holomorphe Funktion existiert. Andererseits kann das Bündel F durch Übergangsfunktionen g_{ij} mit $|g_{ij}| \equiv 1$ beschrieben werden, man hat damit eine Norm $\| \ \|$ auf F, d.h. auf jeder Faser F_x eine Norm $\| \ \|_x$, die reell-analytisch von $x \in R$ abhängt. Durch $\| \ \| < 1$ wird eine relativ-kompakte Umgebung T der Nullschnittfläche in F definiert, deren Rand glatt, reell-analytisch und pseudokonvex, jedoch nirgendwo streng pseudokonvex ist. Ist F speziell so gewählt $(b_1(R) > 0)$, dass keine Tensorpotenz F^k analytisch trivial ist, lässt T nur konstante holomorphe Funktionen zu und ist nicht holomorph-konvex. Ist R insbesondere noch projektiv algebraisch, so ist T ein Meromorphiegebiet und lässt sich als verzweigtes Gebiet einem komplexprojektiven Raum P_n überlagern. Ferner wird ein Gebiet $G \Subset X$ konstruiert, dessen Rand pseudokonvex und bis auf eine 2-codimensionale Teilmenge streng pseudokonvex ist. G ist nicht holomorph-konvex; die Algebra $I(G)$ aller holomorphen Funktionen auf G ist nicht isomorph zur Funktionenalgebra eines Steinschen Raumes. Denn $I(G)$ besitzt Charakterideale, die nicht endlich erzeugbar sind. Es existiert sogar eine 1-codimensionale analytische Menge $A \subset G$, so dass $G - A$ über dem 3-dimensionalen komplexen Zahlenraum C_3 ausgebreitet werden kann und $I(G-A)$ isomorph ist zu $I(G)$. Innerhalb der Kategorie der komplexen Räume lässt sich für $G - A$ keine Holomorphiehülle konstruieren. Der Autor verallgemeinert deshalb den Begriff des komplexen Raumes zum Begriff des komplexen Schemas und spricht die Hoffnung aus, dass innerhalb der Kategorie der komplexen Schemata Holomorphiehüllenbildung stets möglich sei. *W. Kaup* (Erlangen)

Lu, Qi-keng [Look, K. H.] 6055

The elliptic geometry of extended spaces.

Acta Math. Sinica **13** (1963), 49–62 (*Chinese*); *translated as Chinese Math.* **4** (1963), 54–69.

In this paper the author begins by considering the classical space $\Re_I$ as an absolutely extended space, then introduces an elliptic distance between two elements, and shows that the corresponding differential metric is Kählerian. For instance, let $\mathfrak{z}_1, \mathfrak{z}_2$ be two elements in the space of $m\times(m+n)$ matrices, $E(m, m+n)$, and let $\mathfrak{P}(m, n)$ be the space of equivalence classes of elements $\mathfrak{z}_1$ or $\mathfrak{z}_2$ which are related by $\mathfrak{z}_1 = Q\mathfrak{z}_2$, where Q is a nonsingular $m\times m$ matrix. $\Re_I$ is the space $\mathfrak{P}(m, n)$; for a detailed discussion of the other classical domains see L. K. Hua [*Harmonic analysis of functions of several complex variables in the classical domains*, Amer. Math. Soc., Providence, R.I., 1963; MR **30** #2162].

He introduces as a distance in $\mathfrak{P}(m, n)$ between two points $\mathfrak{z}_1, \mathfrak{z}_2$,

$$\sigma(\mathfrak{z}_1, \mathfrak{z}_2) = \arccos \frac{|\det \mathfrak{z}_1\bar{\mathfrak{z}}_2'|}{\sqrt{(\det \mathfrak{z}_1\bar{\mathfrak{z}}_1' \cdot \det \mathfrak{z}_2\bar{\mathfrak{z}}_2')}}$$

(where $\mathfrak{z}'$ denotes the transpose of $\mathfrak{z}$, and $\bar{\mathfrak{z}}$ is the complex conjugate), and shows it satisfies the required conditions for a metric.

In Section II the author introduces an analytic structure on the compact complex analytic manifold $\mathfrak{P}(m, m)$, and derives the differential metric of $\mathfrak{P}(m, n)$ from the definition of the distance $\sigma(\mathfrak{z}_1, \mathfrak{z}_2)$ given in Section I. He obtains as a differential metric the form

$$ds^2 = \operatorname{tr}[d\bar{Z}'(I+Z\bar{Z}')^{-1}\,dZ(I+\bar{Z}'Z)^{-1}] = d\bar{d}\log\det(I+Z\bar{Z}'),$$

where

$$d \equiv \sum_{j=1}^{m}\sum_{\alpha=1}^{n} dz_{j\alpha}\frac{\partial}{\partial z_{j\alpha}}, \qquad \bar{d} \equiv \sum_{j=1}^{m}\sum_{\alpha=1}^{n} d\bar{z}_{j\alpha}\frac{\partial}{\partial \bar{z}_{j\alpha}},$$

where Z is a local coordinate given by

$$Z = (\mathfrak{z}_{i_1}, \cdots, \mathfrak{z}_{i_m})^{-1}(\mathfrak{z}_{i_{m+1}}, \cdots, \mathfrak{z}_{i_{m+n}}),$$

$$\mathfrak{z}_\alpha \equiv \begin{pmatrix}\mathfrak{z}_{1\alpha}\\ \vdots \\ \mathfrak{z}_{m\alpha}\end{pmatrix}, \qquad \mathfrak{z} \equiv (\mathfrak{z}_1, \cdots, \mathfrak{z}_{m+n});$$

$$Z = \begin{pmatrix} z_{11} & \cdots & z_{1n}\\ \cdots & \cdots & \cdots \\ z_{m1} & \cdots & z_{mn}\end{pmatrix}.$$

Using the form of the unitary curvature of $\mathfrak{P}(m, n)$ as given by the author in an earlier work [Advancement in Math. **2** (1956), 567–662; MR **20** #6535] and the fact that the unitary curvature is invariant under analytic transformations, he shows that it is always positive. This result is a special case of a result due to É. Cartan [Bull. Soc. Math. France **54** (1926), 214–264]; however, the curvature is completely written out here.

In Section III the author writes out the expressions for the differential metric and unitary curvature for the submanifolds $\Re_{II}$, $\Re_{III}$, and $\Re_{IV}$.

Bers, Lipman; Ehrenpreis, Leon 6056

Holomorphic convexity of Teichmüller spaces.

Bull. Amer. Math. Soc. **70** (1964), 761–764.

B is the Banach space of analytic functions φ in the lower half-plane $y<0$ with norm $\|\varphi\| = \sup|y^2\varphi(z)|$. The universal Teichmüller space T can be identified with an open subset of B; T is complete in the Teichmüller metric.

If $Q \subset T$, let $h(Q)$ denote the hull of Q with respect to holomorphic functions in T. The authors prove that if Q is bounded in the Teichmüller metric, so is $h(Q)$. As a consequence, finite-dimensional Teichmüller spaces $T(G)$ (G is a finitely generated Fuchsian group of the first kind) are domains of holomorphy.

The result is applied to obtain some refinements of Baily's theorem on the boundary of Teichmüller space [W. L. Baily, Jr., Ann. of Math. (2) **71** (1960), 303–314; MR **22** #1583].

L. V. Ahlfors (Cambridge, Mass.)

Bishop, Errett 6057

Conditions for the analyticity of certain sets.

Michigan Math. J. **11** (1964), 289–304.

Results about the limit and the continuation of analytic sets with bounded volume are obtained by using methods of functional analysis. They go much further and complete previous partial results.

Let v be the $2k$-dimensional Hausdorff measure in $\mathbf{C}^n$, where $n>k>0$. Suppose that $\{A_m\}$ is a sequence of analytic sets of pure complex dimension k in the open subset U of $\mathbf{C}^n$. Suppose that $A_m\to A$ for $m\to\infty$ and that $v(A_m)$ is bounded. Then $\bar{A}\cap U$ is analytic in U. This theorem was conjectured by Oka [J. Sci. Hiroshima Univ. A **4** (1934), 93–98] and proved by Rutishauser [Acta Math. **83** (1950), 249–325; MR **12**, 90] and Nishino [J. Math. Kyoto Univ. **1** (1961/62), 357–377; MR **26** #6441] in the case $k = n-1 = 1$, and by the reviewer [Math. Z. **84** (1964), 154–218; MR **29** #2431] in the case $k = n-1$.

Suppose that B is an analytic subset of dimension p of the open subset U of $\mathbf{C}^n$. Let A be an analytic subset of pure complex dimension k in $U-B$. Suppose that $v(A)<\infty$. Then $U\cap\bar{A}$ is analytic in U. This theorem generalizes a theorem of Remmert and Stein [Math. Ann. **126** (1953), 263–306; MR **15**, 615]. In the case $p=k$, the theorem was proved by the reviewer [Arch. Math. **9** (1958), 167–175; MR **21** #729].

The Remmert-Stein theorem can be generalized further with the introduction of sets of capacity zero. Suppose that B is a relative closed subset of the open bounded set U of $\mathbf{C}^n$. Let A be an analytic subset of pure dimension k on U with $B \subseteq \bar{A}$. Suppose that B has capacity zero relative to the algebra of all continuous functions on $\bar{A}$ which are holomorphic on A. Let S be an open and connected subset of $\mathbf{C}^k$. Let $\pi: U\to S$ be surjective and holomorphic. Suppose that $\pi\,|\,B: B\to S$ is proper, with $\pi(B)\neq S$. Then $\bar{A}\cap U$ is analytic in U.

It should be noted that the constant c of Lemma 3 was introduced by P. Lelong [Bull. Soc. Math. France **85** (1957), 239–262; MR **20** #2465], that c depends on k but not on n, and that $c=\pi^k/k!$ is the best possible choice of c.

On the compactification of arithmetically defined quotients of bounded symmetric domains.

Bull. Amer. Math. Soc. **70** (1964), 588–593.

This is a brief announcement of the results extending earlier results [*Séminaire H. Cartan*, 1957/58, Secrétariat

mathématique, Paris, 1958; MR **21** #2750; W. L. Baily, Jr., Amer. J. Math. **81** (1959), 846–874; MR **22** #12244; I. I. Pjateckiĭ-Šapiro, *Geometry of classical domains and theory of automorphic functions*, Fizmatgiz, Moscow, 1961; MR **25** #231] to the most general case, of which a full account is supposed to be published elsewhere. Let X be a hermitian symmetric space of non-compact type. One considers a (connected) semi-simple linear algebraic group G $(\subset GL(m, \mathbf{C}))$ defined over $\mathbf{Q}$ such that the symmetric space associated with $G_{\mathbf{R}}$ is equal to X, i.e., $X = K\backslash G_{\mathbf{R}}$, where K is a maximal compact subgroup of $G_{\mathbf{R}}$. (As usual, for every subring B of $\mathbf{C}$, one puts $G_B = G \cap GL(m, B)$.) Let Γ be an "arithmetic subgroup" of G, i.e., a subgroup of $G_{\mathbf{Q}}$ commensurable with the group $G_{\mathbf{Z}}$ of units of G; then Γ acts on X (from the right) in a properly discontinuous manner, and the quotient space X/Γ carries a natural ringed structure with which it becomes an irreducible normal analytic space. Since the main purpose of the paper is to construct a suitable compactification of X/Γ, one may assume that X/Γ is not compact, which implies, in particular, that $G_{\mathbf{R}}$ has no compact simple factor $\neq (e)$; for simplicity, one further assumes that G is strictly simple over $\mathbf{Q}$ (i.e., that it has no proper invariant subgroup $\neq (e)$ over $\mathbf{Q}$). Now the first step is to define the notion of "rational boundary component" for the natural compactification $\bar{X}$ of X (i.e., the closure of X in the Harish-Chandra realization as a bounded symmetric domain). This being done in a very ingenious way, it turns out that, for a rational boundary component F of X (with respect to Γ), the complexification $\mathfrak{N}(F)_{\mathbf{C}}$ of the normalizer $\mathfrak{N}(F) = \{g \in G_{\mathbf{R}} \mid Fg = F\}$ is a proper maximal parabolic subgroup defined over $\mathbf{Q}$ of G, and actually the map $F \to \mathfrak{N}(F)_{\mathbf{C}}$ gives a one-to-one correspondence between the rational boundary components of X (with respect to Γ) and the proper maximal parabolic subgroups over $\mathbf{Q}$ of G (Theorem 1). Then, denoting by X^* the union of X and all rational boundary components, one introduces a topology on X^* in a natural way (but still making use of a fundamental set for Γ) so that $V^* = X^*/\Gamma$ becomes a compact Hausdorff space. From the construction, one has $V^* = V \cup V_1 \cup \cdots \cup V_t$ with $V_i = F_i/\Gamma(F_i)$, where $V = X/\Gamma$ is open, everywhere dense, the F_i's are such that the corresponding groups $\mathfrak{N}(F_i)_{\mathbf{C}}$ form a system of representatives for the equivalence-classes, modulo inner automorphisms by elements of Γ, of proper maximal parabolic subgroups over $\mathbf{Q}$ of G, and $\Gamma(F_i)$ is an arithmetic group acting on F_i, obtained as a homomorphic image of $\mathfrak{N}(F_i) \cap \Gamma$. Next, to define an analytic structure on V^*, one calls a complex-valued function f defined on an open subset U of V^* an $\mathscr{K}$-function on U if it is continuous and if its restriction to $V \cap U$ and to $V_i \cap U$ is analytic in the given analytic structure $(1 \leq i \leq t)$. Then, by arguments similar to those used in the previous papers [loc. cit.] and by considerations of Poincaré-Eisenstein series, the constructions of which depend essentially on the realization of X as a Siegel domain of the third kind for a given boundary component [cf. Pjateckiĭ-Šapiro, loc. cit.; and A. Korányi and J. Wolf, "Generalized Cayley transforms of bounded symmetric domains", Ann. of Math. (2) (to appear)], the authors show finally that V^*, provided with the ringed structure defined by the sheaf of $\mathscr{K}$-functions, becomes a normal analytic space projectively embeddable as a projectively normal algebraic variety by means of a set of automorphic forms for Γ of some suitably high weight (Theorem 3). As a corollary, a generalization of Köcher's theorem and the finiteness of the dimension of the space of automorphic forms (for G with dim $G > 3$) are mentioned, together with some comments on the other approaches to the same results.

I. Satake (Chicago, Ill.)

Gunning, R. C. 6059

Differential operators preserving relations of automorphy.

Trans. Amer. Math. Soc. **108** (1963), 326–352.

Let $\mathfrak{H}$ be a domain in C^n (or more generally a complex manifold) and let G be a group of complex analytic automorphisms of $\mathfrak{H}$. Let V be a (finite-dimensional) complex vector space and denote by $\Phi(V)$ $[\Theta(V)]$ the space of C^∞-mappings [holomorphic mappings] of $\mathfrak{H}$ into V. If $\rho(M, z)$ $(M \in G, z \in \mathfrak{H})$ is a $GL(V)$-valued factor of automorphy for the action of G on $\mathfrak{H}$, the group G acts as a group of linear transformations on the space $\Phi(V)$ by putting

$$(T_\rho(M^{-1})f)(z) = \rho(M, z)^{-1}f(Mz).$$

Under this action of G, the subspace $\Theta(V)$ of $\Phi(V)$ is stable under G. Let W be another complex vector space. A linear mapping $D: \Phi(V) \to \Phi(W)$ is called a holomorphic differential mapping of order ν if we have

$$(DF)(z) = \sum_{s=0}^{\nu} \sum_{i_1, \cdots, i_s} A_{i_1 \cdots i_s}(z) \cdot \partial^s F(z)/\partial z_{i_1} \cdots \partial z_{i_s}$$

for all $F \in \Phi(V)$, where $A_{i_1, \cdots, i_s}(z)$ are the holomorphic mappings from $\mathfrak{H}$ into the complex vector space Hom(V, W). The restriction of D defines a linear mapping $D: \Theta(V) \to \Theta(W)$. When $\hat{\rho}(M, z)$ is a $GL(W)$-valued factor of automorphy, we can also define the action $f \to T_{\hat{\rho}}(M)f$ of G on $\Phi(W)$, and we call a holomorphic differential mapping $D: \Phi(V) \to \Phi(W)$ a G-homomorphism if we have

$$T_{\hat{\rho}}(M) \cdot D = D \cdot T_\rho(M)$$

for all $M \in G$.

In this paper the author studies the problem of determining the holomorphic differential G-homomorphisms in the following situation: $\mathfrak{H}$ is the Siegel upper half-space, G is the symplectic group or a general subgroup thereof and the factors of automorphy are of the form $\rho(Cz + D)$. After obtaining various general results on the holomorphic differential G-homomorphisms, the author determines the holomorphic differential G-homomorphisms of orders 1 and 2 for the Siegel upper half-space of rank 2 and indicates some of the applications of these results.

Y. Matsushima (Osaka)

Maass, Hans 6060

Über die gleichmässige Konvergenz der Poincaréschen Reihen n-ten Grades.

Nachr. Akad. Wiss. Göttingen Math.-Phys. Kl. II **1964**, 137–144.

Let $S(Z) = (AZ + B)(CZ + D)^{-1}$ be a transformation of the Siegel modular group of degree n. The Poincaré series of dimension $-k$ is defined as

$$g_{-k}(Z, T) = e^{2\pi i\sigma(TS(Z))}|CZ + D|^{-k},$$

where k is an even positive integer, $Z = X + iY$, $Y > 0$, $T \geq 0$ is a semi-integral symmetric matrix of rank r, S runs over a certain reduced set of modular matrices, and σ is the trace. The object of this paper is to prove the Theorem:

The series $g_{-k}(Z, T)$ for $k > n+1+r$ converges absolutely and uniformly in each region $Y \geq (1/m)E$, $\sigma(X^2) \leq m$. Here $m > 0$ and E is the identity matrix.

Up to now only the absolute convergence of the Eisenstein series ($T = 0$) had been known. Both the plan of the proof and Lemma 1 are attributed to C. L. Siegel.

The author proceeds by introducing a majorant for g_{-k}, which is essentially

$$\sum_{(C,D)} \varphi(Z; C, D)\|CZ+D\|^{-k},$$

with

$$\varphi(Z; C, D) = \sum_{P} e^{-2\pi\delta\sigma(Y_S(P))},$$

where δ, $0 < \delta < 1$, depends on T, Y_S is the imaginary part of $S(Z)$, and C, D, P are matrices with certain ranges. Lemma 1: $|Y|\Delta_k(Z) \geq c\Delta_k(iE)$, where Δ_k is a principal subdeterminant of the matrix $\begin{pmatrix} Y & 0 \\ 0 & Y^{-1}\end{pmatrix}\begin{pmatrix} C' \\ XC'+D'\end{pmatrix}$; C and D form the lower row of a transformation $S(Z)$, and c depends only on m and n. Lemma 2: For $k > n+1$ the Eisenstein series $g_{-k}(Z, 0)$ converges uniformly in each domain of the type stated in the Theorem.

The proof of Lemma 2 is made from the estimate

$$\varphi_p(Z; C, D)\|CZ+D\|^{-k} \leq c_1 p^{-2(k-r)},$$

where φ_p is φ restricted to $\sigma(P'P) \geq p^2$ and c_1 depends on m, n, r, δ, C, D.

The Theorem follows from the above three results.

J. Lehner (College Park, Md.)

Igusa, Jun-ichi 6061

On Siegel modular forms of genus two. II.

Amer. J. Math. **86** (1964), 392–412.

The author continues his intrepid investigation [Part I appeared in same J. **84** (1962), 175–200; MR **25** #5040] of the modular varieties in genus 2, using in an essential way the ideas and results of his work on theta constants [ibid. **86** (1964), 219–246; MR **29** #2258].

Let $\Gamma(n)$ be the modular group of level n acting on the Siegel upper half-plane $\mathfrak{S}_2$ of genus 2. Thus $\Gamma(1) = \mathrm{Sp}(2, \mathbf{Z})$ and there is a chain of natural subgroups $\Gamma(1) \supset \Gamma(2) \supset \Gamma(2, 4) \supset \Gamma(4, 8)$. Let $A(\Gamma)$ be the graded ring of modular forms with respect to Γ of different weights, and let $V(\Gamma) = \mathrm{proj}\, A(\Gamma)$ denote the corresponding projective variety. The main geometric results then are that $V(\Gamma(2, 4))$ is nonsingular; thus $V(\Gamma(1))$ and $V(\Gamma(2))$ have a nonsingular covering. On the other hand, it is proved that there is a singular point on $V(\Gamma(4))$ which has no local nonsingular covering, and this result easily extends to all $V(\Gamma(n))$, $n \geq 3$.

The general line of argument uses the ten theta constants θ_m for genus 2. He proves $\mathbf{C}(\theta_m\theta_n)$ is integrally closed, which shows by the second paper cited above that it coincides with $A(\Gamma(4, 8))$; this gives a hold on the structure of the latter. One then obtains the other $A(\Gamma)$ as the subrings of $A(\Gamma(4, 8))$ invariant under the corresponding finite groups; the passage from $A(\Gamma(2))$ to $A(\Gamma(1))$ requires an analysis of the representation of $\Gamma(2)/\Gamma(1)$ on the former ring. The result about $V(\Gamma(4))$ is obtained by studying it locally as a covering of the nonsingular $V(\Gamma(2, 4))$.

Along the way, a new proof is given for the structure of $A(\Gamma(1))$, and explicit formulas for the basic Eisenstein series of level one in terms of the θ_m are given. The paper is almost entirely algebraic.

A. Mattuck (Cambridge, Mass.)

Christian, Ulrich 6062

Bestimmung des Körpergrades der Siegelschen Modulfunktionen über den Eisensteinreihen.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 171–172.

Es sei $\Gamma(q)$ die Hauptkongruenzuntergruppe q-ter Stufe der Siegelschen Modulgruppe n-ten Grades Γ. Früher [Math. Ann. **152** (1963), 275–341; MR **28** #2256] hatte der Autor bemerkt, dass der Körper $m(q)$ der zugehörigen Modulfunktionen nur in den Fällen $n \equiv 1$ (2) und $n \equiv 0$ (2), $q = 1, 2, 4, p^\nu, 2p^\nu$ (p ungerade Primzahl, $\nu = 1, 2, \cdots$) durch die Eisensteinreihen erzeugt wird. In der vorliegenden Note wird der Körpergrad von $m(q)$ über dem Körper $e(q)$ derjenigen Modulfunktionen, welche durch die Eisensteinreihen rational dargestellt werden können, ergänzend angegeben. Es sei $n \equiv 0$ (2), $q \geq 3$. Die zu $\Gamma(q)$ gebildeten Eisensteinreihen sind nämlich in Wahrheit sogar Modulformen bezüglich der Kongruenzgruppe $\Gamma^*(q) = \{M \in \Gamma \mid M \equiv uE\ (q),\ u^2 \equiv 1\ (q)\}$, und nach früheren Resultaten ist einerseits der zugehörige Funktionenkörper $m^*(q) = e(q)$ und andererseits $[m(q) : m^*(q)] = \frac{1}{2}[\Gamma^*(q) : \Gamma(q)]$. Es ergibt sich also durch elementare Bestimmung des Gruppenindex $[\Gamma^*(q) : \Gamma(q)]$ das Resultat $[m(q) : e(q)] = 2^{r+s-1}$, wobei r die Anzahl der ungeraden Primteiler von q und $s = 0, 1, 2$ je nachdem $4 \nmid q$, $4 \mid q$ und $8 \nmid q$, $8 \mid q$ ist.

Christian, Ulrich 6063

Über die Modulgruppe zweiten Grades. I, II.

Math. Z. **85** (1964), 1–28; *ibid.* **85** (1964), 29–39.

Seien $Z(n)$ der Siegelsche Halbraum und $\Gamma(n)$ die Siegelsche Modulgruppe n-ten Grades. Der Quotientenraum $Q(n) = Z(n)/\Gamma(n)$ lässt sich nach Satake, Siegel, und Verfasser in der Gestalt

$$\tilde{Q}(n) = Q(n) \cup Q(n-1) \cup \cdots \cup Q(0)$$

kompaktifizieren. Die Frage nach der Uniformisierbarkeit der Punkte von $\tilde{Q}(n)$ wurde früher für $n \geq 3$ vom Verfasser [Math. Ann. **152** (1963), 275–341; MR **28** #2256] und für $n = 2$ von Igusa [Amer. J. Math. **84** (1962), 175–200; MR **25** #5040] mit recht tiefliegenden Hilfsmitteln behandelt. Die vorliegende Arbeit betrifft den Fall $n = 2$ und gibt einfache neue Beweise für die Ergebnisse von Igusa in expliziter Darstellung. Das Hauptresultat von Teil I ist der Nachweis der Uniformisierbarkeit des Punktes $Q(0)$ in $\tilde{Q}(2)$. Verfasser benutzt seine verwendete Beschreibung [loc. cit.] der Umgebungen von $Q(0)$. In die Rechnungen geht wesentlich ein die einfache Gestalt der Minkowskischen Reduktionsbedingungen im binären Fall. Als Ortsuniformisierende von $Q(0)$ werden Funktionen folgender Art verwendet:

$$F(Z) = \sum e^{2\pi i(\mathrm{Sp}\, SZ)},$$

wobei über alle symmetrischen S summiert wird, die zu einer festen Kantenmatrix der Minkowskischen Pyramide unimodular äquivalent sind. Anschliessend werden einige Folgerungen aus diesem Uniformisierungssatz gezogen. Im zweiten Teil werden Thetafunktionen benutzt, um die Uniformisierbarkeit der Punkte von $Q(1)$ in $\tilde{Q}(2)$ zu untersuchen. Sämtliche Punkte von $Q(1)$ sind uniformisierbar

mit der genauen Ausnahme von denjenigen, die i und $1/2+i\sqrt{3}/2 \in Z(1)$ entsprechen. Dort liegen Singularitäten vor. *H. Klingen* (Freiburg)

Helwig, Karl-Heinz 6064

Automorphismengruppen des allgemeinen Kreiskegels und des zugehörigen Halbraumes.

Math. Ann. **157** (1964), 1–33.

Ein n-dimensionaler Kreiskegel Y_n ist eine Teilmenge eines normierten Vektorraumes X über dem Körper R der reellen Zahlen, die in einer geeigneten Basis von X durch die Bedingungen

$$(y_1, \cdots, y_n) \in X, \quad y_1^2 - y_2^2 - \cdots - y_n^2 > 0, \qquad y_1 > 0,$$

beschrieben wird. Y_n ist einer der vier Haupttypen der von M. Koecher [Amer. J. Math. **79** (1957), 575–596; MR **19**, 867] eingeführten homogenen Positivitätsbereiche mit positiver Charakteristik. In der vorliegenden Arbeit werden alle linearen Automorphismen von Y_n sowie alle holomorphen Automorphismen des zugehörigen Halbraumes $Z_n = R^n + iY_n$ bestimmt. Ferner werden durch einen arithmetischen Prozeß diskontinuierliche Automorphismengruppen von Z_n ("Modulgruppen") konstruiert, die einen ähnlichen Fundamentalbereich besitzen wie die bekannten Modulgruppen im Siegelschen Halbraum. Dadurch ist es möglich geworden, die Theorie Siegelscher Modulformen und Modulfunktionen auf Z_n zu übertragen.

SPECIAL FUNCTIONS

See also 5796, 5798a–b, 6244, 6608, 6609, 6610a–b, 6800.

Mitrinović, Dragoslav S.; Doković, Dragomir Ž. 6065

★Specijalne funkcije [Special functions].

Izdavačko Preduzeće Građevinska Knjiga, Belgrade, 1964. 267 *pp.*

This exposition of special functions is based upon Mitrinović's lectures to engineering and physics students in Belgrade. Each chapter contains the definition and fundamental properties of the class of functions in question, a set of problems, and further references. The book concludes with a collection of tables of numerical values and of graphs. The treatment is more expansive than a simple collection of formulas, but does have a little of this character and could be used in the same way as Magnus and Oberhettinger [*Formeln und Sätze für die speziellen Funktionen der mathematischen Physik*, second edition, Springer, Berlin, 1948; MR **10**, 38] and Jahnke, Emde and Lösch [*Tables of higher functions*, sixth edition, McGraw-Hill, New York, 1960; MR **22** #5140]. The chapter headings are as follows: The gamma and beta functions; Legendre polynomials; Laguerre polynomials; Hermite polynomials; Chebyshev polynomials; Orthogonal polynomials; Bessel functions; The Laplace equation and special functions; Elliptic functions; Numerical tables; Graphs of some special functions. *J. V. Wehausen* (Berkeley, Calif.)

Bhowmic, K. N. [Bhowmick, K. N.] 6066

A generalized Struve's function and its recurrence formula. (Hindi. English summary)

Vijnana Parishad Anusandhan Patrika **6** (1963), 1–11.

Define the generalized Struve function $H_\nu^\lambda(z)$ by the formula

$$(*) \qquad H_\nu^\lambda(z) = \sum_{r=0}^{\infty} \frac{(-1)^r (z/2)^{\nu+2r+1}}{\Gamma(r+3/2)\Gamma(\nu+\lambda r+3/2)}, \qquad \lambda > 0.$$

The author discusses the absolute convergence of the series on the right-hand side of (*) and then proves nine recurrence relations. The recurrence relations can also be found stated in the author's paper [Gaṇita **14** (1963), 89–97; MR **29** #4922]. *W. A. Al-Salam* (Lubbock, Tex.)

Smith-White, W. B.; Buchwald, V. T. 6067

A generalization of $z!$.

J. Austral. Math. Soc. **4** (1964), 327–341.

Authors' summary: "A generalized factorial function $(z:k)!$ is defined as an infinite product similar to the Euler product for $z!$, but with the sequences of integers replaced by the roots of $F(z) = \sin \pi z + k\pi z$. It is proved that, apart from poles in $\mathscr{R}(z) < 0$, $(z:k)!$ is analytic in both variables, and that $F(z)$ may be expressed in the form $F(z) = \pi z/(z:k)!(-z:k)!$. As $|z| \to \infty$, it is shown that the function satisfies a Stirling formula $(z:k)! \sim \sqrt{(2\pi z)} z^z e^{-z}$."

{Reviewer's remarks: This paper gives a concise and rigorous demonstration of the results announced in the summary. As expected, most of the properties of $(z:k)!$ are analogues of the corresponding features of the gamma function. For a special case see #6068 below.}

Chatterjea, S. K. 6073

New class of polynomials.

Ann. Mat. Pura Appl. (4) **65** (1964), 35–48.

The new class of polynomials is defined by a Rodrigues type formula:

$$M_n(x,k) = x^{(2-k)n}k^{-n}e^{kx}D^n(x^{kn}e^{-kx}), \qquad k=2,3,\cdots.$$

where k is a parameter. These become the Bessel polynomials when $k=2$. An explicit formula is derived for $M_n(x,k)$. For $m_n(x,k)=x^nM_n(1/x,k)$, it is shown that $(-k)^nm_n(x/k,k)=n!L_n^{(-kn-1)}(x)$, where $L_n^{(\alpha)}$ is the Laguerre polynomial. The differential equation and operational formulas for $m_n(x,k)$ are derived.

It is shown that $M_n(x,3)=y_n(x,n+2,3)$, where $y_n(x,a,b)$ is the generalized Bessel polynomial.

Sur les fonctions de Bessel modifiées de première espèce d'ordre entier de plusieurs variables.

Univ. Beograd. Publ. Elektrotehn. Fak. Ser. Mat. Fiz. No. 122–129 (1964), 27–29.

As a generalization of Jekhowsky's definition [J. Math. Pures Appl. (9) **41** (1962), 319–337; MR **26** #3940], the author introduces the modified Bessel function of the first kind in n variables by the coefficients of the series

$$\exp\left\{\sum_{m=1}^{n}\frac{x_m}{2}(u^m+u^{-m})\right\} = \sum_{k=-\infty}^{+\infty} I_k(x_1,x_2,\cdots,x_n)u^k.$$

Then the author discusses several properties of the function $I_k(x_1,\cdots,x_n)$, e.g., integral representations, recursion formulas, etc., and announces the addition theorem and the differential equations which are satisfied by the function I_k for $n=3,4$. The demonstrations and further development will be published in Mat. Vesnik **1** (1964).

Keane, A.; Clancy, B. E. 6077

Doppler broadened contour functions in the complex domain.

J. Austral. Math. Soc. **4** (1964), 354–362.

Starting from the known definition of the Doppler broadened contour functions (Voigt profiles), $\Psi(x,t)$ and $\Phi(x,t)$, and the differential equations for them, as well as for the function $\chi(x,t)=\Psi+i\Phi$, the authors deduce integrals representing them, the asymptotic expansions for the upper and lower half-planes being added. Then, taking a contour consisting of the real axis and the semicircle ($R\to\infty$) in the upper half-plane, they calculate many integrals taken along the real axis, especially for the functions χ^n, $x^k\chi^n$, $\chi^n/(x-a)$, $\chi^n/(x^2+a^2)$.

Z. Janković (Zagreb)

Ilieff, L. [Iliev, Ljubomir] 6078

Turánsche Ungleichungen.

C. R. Acad. Bulgare Sci. **17** (1964), 693–696.

An infinite sequence of real numbers $\{\alpha_n\}$ is called a sequence of the first kind if (A) for any polynomial $a_0+a_1z+\cdots+a_nz^n$ having only real zeros it follows that (B) $\alpha_0a_0+\alpha_1a_1z+\cdots+\alpha_na_nz^n$ has only real zeros.

If in (A) the zeros are all of one sign or zero, then $\{\alpha_n\}$ is called a sequence of the second kind.

Pólya and Schur [J. Reine Angew. Math. **144** (1914), 89–113] have shown that sequences of the first and second kinds satisfy Turán's inequality: $\alpha_n^2-\alpha_{n-1}\alpha_{n+1}\geq 0$, $n=1,2,\cdots$. In the present paper, it is shown that sequences of the first kind satisfy

$$\alpha_n^2-\alpha_{n-2}\alpha_{n+2}\geq 0, \qquad n=2,3,\cdots.$$

$$\left(\frac{\alpha_{n-2}}{\alpha_n}\right)^2-\left(\frac{\alpha_{n-2}}{\alpha_n}\right)^2\leq 0, \qquad n=3,4,\cdots.$$

An entire function

$$\varphi(z)=\alpha_0+\alpha_1 z+\frac{\alpha_2 z^2}{2!}+\cdots$$

with only real zeros of the same sign is called a function of type I if either $\varphi(z)$ or $\varphi(-z)$ can be represented in the form:

$$\varphi(z)=\frac{\alpha_r}{r!}z^r e^{\gamma z}\prod_{k=1}^{\infty}(1+\gamma_k z), \qquad \alpha_r\neq 0,\ \gamma\geq 0,\ \gamma_k>0.$$

An entire function

$$\psi(z)=\beta_0+\beta_1 z+\frac{\beta_2 z^2}{2!}+\cdots$$

with only real zeros is called a function of type II if

$$\psi(z)=\frac{\beta_r}{r!}z^r e^{-\gamma z^2+\delta z}\prod_{k=1}^{\infty}(1+\delta_k z)e^{-\delta_k z},$$

$\beta_r,\delta,\delta_1,\delta_2,\cdots$ real, $\gamma\geq 0$.

Pólya and Schur [loc. cit.] have shown that $\{\alpha_n\}$ is a sequence of the first kind if and only if φ is a function of type I, and $\{\beta_n\}$ is a sequence of the second kind if and only if ψ is a function of type II. It follows readily that if $f_k(z)$, $k=1,2,\cdots,s$, are of type II and

$$\text{(C)}\qquad F(z)=\prod_{k=1}^{s}f_k(x_k z)=\sum_{n=0}^{\infty}R_n(x_1,x_2,\cdots,x_s)\frac{z^n}{n!},$$

then $\{R_n\}$ is a sequence of the second kind, where R_n is a polynomial in the real variables $x_1,x_2,\cdots,x_s$. If $f_k(z)$ are of type I, then $\{R_n\}$, with $x_1,x_2,\cdots,x_s$ assuming values of one sign only, is of the first kind.

Using known representations of the form (C) for some of the classical orthogonal polynomials, sequences of these polynomials are classified as being of first or second kind.

A. E. Danese (Buffalo, N.Y.)

Kishore, Nand 6079

The Rayleigh polynomial.

Proc. Amer. Math. Soc. **15** (1964), 911–917.

The Rayleigh function $\sigma_{2n}(\nu)$ and the Rayleigh polynomial $\phi_{2n}(\nu)$ are defined by

$$\sigma_{2n}(\nu)=\sum_{m=1}^{\infty}(j_{\nu,m})^{-2n}$$

$$(n=1,2,3,\cdots),$$

$$\phi_{2n}(\nu)=4^n\prod_{k=1}^{n}(\nu+k)^{[n/k]}\cdot\sigma_{2n}(\nu),$$

where the $j_{\nu,m}$ are the zeros of $z^{-\nu}J_\nu(z)$. Making use of some properties of $\sigma_{2n}(\nu)$ proved in an earlier paper [same Proc. **14** (1963), 527–533; MR **27** #1633], the author now obtains the following results. The degree d_n of $\phi_{2n}(\nu)$ is determined by

$$d_n=1-2n+\sum_{k=1}^{n}\left[\frac{n}{k}\right].$$

Put $\phi_{2n}(\nu)=\sum_1^{d_n}a_{nk}\nu^k$; then the a_{nk} are positive integers. It is proved that the real roots of $\phi_{2n}(\nu)=0$ lie in the interval $(-n,-2)$. Finally, the author obtains some congruences satisfied by $\phi_{2n}(\nu)$. The general formulas are rather complicated; the following special cases may be noted:

$$\phi_{2n}(\nu)\equiv 2\phi_{2n-2}(\nu)\pmod{\nu+n-1},$$

where n is an odd prime,

$$(-1)^{n-1}(n-1)!\,\phi_{2n}(\nu)\equiv\prod_{r=1}^{[n/2]}(\nu+r)^{[n/r]-1}\pmod{\nu+n}.$$

Medvedev, V. A. 6080

On the convergence of orthogonal series of Laguerre, Hermite and Jacobi. (Russian)

Dokl. Akad. Nauk SSSR **151** (1963), 1031–1034.

The Laguerre, Hermite and Jacobi polynomials are shown to be complete with respect to the set of functions $\varphi(x)$ which, together with their first $k-1$ derivatives, are absolutely continuous and whose kth derivative is in L_2, all for the interval (a,b) appropriate for the respective polynomials, and for which the norm is taken as $\|\varphi\|^2=\int_a^b\sum_{m=0}^{k}|d^m\varphi/dx^m|^2\,dx$. *R. G. Langebartel* (Urbana, Ill.)

Rangarajan, S. K. 6081

On some infinite series involving Appell-polynomials and the functions $F(z,\alpha)$. I.

Proc. Indian Acad. Sci. Sect. A **60** (1964), 153–158.

The identity

$$\sum\psi_r(x)F(y,\alpha+r)\frac{z^r}{r!}=\sum\psi_r(0)F(y+zx,\alpha+r)\frac{z^r}{r!}$$

is established, where $\psi_r(x)/r!$ is the Appell polynomial defined by $\psi_n(x)=\sum_{r=0}^{n}\binom{n}{r}\psi_r(0)x^{n-r}$ and $F(z,\alpha)$ satisfies the functional relation

$$\frac{\partial}{\partial z}F(z,\alpha)=F(z,\alpha+1)$$

(see C. Truesdell, *An essay toward a unified theory of special functions* [Princeton Univ. Press, Princeton, N.J., 1948; MR **9**, 431] for a detailed treatment of this functional equation).

The foregoing identity is used to sum a large number of series. For example:

$$\sum\frac{n!}{(\alpha+1)_n}L_n^{\alpha}(x)L_n^{\beta-n}(y)z^n=$$

$$e^{-yz}(1+z)^{\beta}\Phi_2\left(-\beta,\alpha+1,\frac{xz}{1+z};zyz\right),$$

where L_n^{α} is the Laguerre polynomial and Φ is a confluent hypergeometric function.

★Équations différentielles.

Formulaire de Mathématiques à l'Usage des Physiciens et des Ingénieurs, Fasc. VI. Centre d'Études Mathématiques en Vue des Applications. Institut Henri Poincaré.

Centre National de la Recherche Scientifique, Paris, 1964. 78 *pp*.

This booklet consists of a summary of results from the theory of ordinary differential equations intended for the use of physicists and engineers. After an introduction dealing with elementary methods of integration, Part I covers existence theorems, linear differential equations, and eigenvalue problems. Part II deals with differential equations in the complex domain. The material up to this point may be found in the well-known treatise by Ince. However, Part III by Reeb contains some results not readily available elsewhere. It covers dynamical systems, topological theory of 2-dimensional autonomous systems, application of fixed-point theorems, and perturbation procedures. {The book contains several printing errors.}

The early sections seem based on a traditional course in differential equations without regard for applications. Thus Clairaut's equation is included, but there is no mention of numerical methods or dependence of solutions on parameters. One could have wished for more sections like Part III, dealing with stability, singular perturbation problems, and so on. *W. A. Coppel* (Canberra)

Sur quelques nouvelles classes d'équations différentielles intégrables non-linéaires du premier et du deuxième ordre.

Bol. Soc. Mat. São Paulo **15** (1960), 81–93 (1964).

The second-order differential equation

$$(1)\quad f(y, y')y'' + \phi(y, y') = e^{\beta x}\psi(y, y') \qquad (\beta = \text{const}),$$

where as functions of y, y' the functions f, ϕ and ψ are homogeneous of respective degrees m, $m+1$ and n, is shown to be reducible to a first-order Abel equation of the form

$$(2)\qquad u' = a_0(x)u^3 + a_1(x)u^2.$$

In particular, equation (2) is utilized in determining new conditions of integrability for certain second-order nonlinear differential equations, as well as for the specific solution of some first-order equations that are obtainable from (1) by a suitable change of variable in case $\beta = 0$. *W. T. Reid* (Norman, Okla.)

Baranov, A. V. 6086

A new method of solving differential equations of the type

$$f_n(x)\frac{d}{dx}f_{n-1}(x)\frac{d}{dx}\cdots f_1(x)\frac{dy}{dx} - y(x) = f(x).$$

(Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 920–926.

The general solution of this equation is given in the form of a series. The terms of the series can be found by a recurrence formula. The expansion is valid under sufficiently weak conditions: boundedness of certain functions involving $f, f_1, f_2, \cdots, f_n$. It is shown that, in certain cases, the partial sums are successively the upper and lower bounds of the exact particular solution. The same method of integration was employed by P. A. Murav'ev [Bul. Inst. Politehn. Bucureşti **24** (1962), no. 3, 13–34; MR **27** #372] for a more general differential equation. *D. Ž. Djoković* (Belgrade)

Iwano, Masahiro 6087

Asymptotic solutions of Whittaker's differential equation as the moduli of the independent variable and two parameters tend to infinity.

Japan. J. Math. **33** (1963), 1–92.

Consider Whittaker's differential equation

$$\frac{d^2W}{dt^2} + \left[-\frac{1}{4} + \frac{k}{t} + \frac{\frac{1}{4} - n^2}{t^2}\right]W = 0$$

for large complex values of t and of the two parameters k and n. The author's aim is to solve this equation by means of asymptotic series that are valid as all three variables t, k and n tend to infinity. The nature of the series depends decisively on the relative sizes of these three variables in the passage to the limit. The author succeeds in dividing the neighborhood of the point $t = \infty$, $k = \infty$, $n = \infty$ of the (t, k, n)-space into a finite number of subdomains such that in each of them a pair of formally linearly independent formal series solutions can be constructed. It is then shown that these formal series are asymptotic expansions of true solutions, at least in sufficiently narrow subsectors of the respective subdomains. Since each subdomain can be covered by finitely many such sectors, the neighborhood of $t = k = n = \infty$ is completely covered by a finite set of domains in each of which the differential equation can be

olved by asymptotic series. There remains the problem of inding the linear relations between these several expansions. This "connecting problem" is not discussed in the paper. In fact, in view of the complexity of the situation, as revealed by the author's analysis, an exhaustive description of the connecting relations may well be an unrewarding, if not an impossible, task. There are altogether no less than 46 subdomains, each of which requires a separate analysis, and every one of these subdomains must be subdivided into an unspecified number of sectors.

The method of the paper resembles that of a paper by the author and Sibuya [Kôdai Math. Sem. Rep. **15** (1963), -28; MR **26** #6530]. In that article differential equations with one parameter only were considered. The presence of two independent parameters leads to enormous complications.

The construction of the subregions is based on a geometric argument involving convex polyhedra that may be regarded as three-dimensional generalizations of the Newton-Puiseux polygons. *W. Wasow* (New York)

Ahundov, A. M.; Toraev, A. 6088

On the solutions of a differential equation. (Russian)

Izv. Akad. Nauk Turkmen. SSR Ser. Fiz.-Tehn. Him. Geol. Nauk **1964**, no. 1, 21–23.

Consider the differential equation

$$(1)\qquad y''+P_1(x)y'+P_2(x)y=0,$$

where $P_1(x)$ and $P_2(x)$ are continuous functions on $x_0\le x<\infty$. The authors prove five theorems concerning oscillatory solutions of (1), the basic theorem being the following: If the coefficients of (1) are of fixed signs and if $P_1(x)<0$, $P_2(x)>0$ or $P_1(x)<0$, $P_2(x)<0$, then between two consecutive roots of a solution of (1) there are at most two roots of any other solution. The authors claim that their theorems remain in force also for the general equation of order three and for the case where $P_1(x)$ vanishes at certain points [cf. also L. D. Nikolenko, Dokl. Akad. Nauk SSSR **114** (1957), 483–485; MR **19**, 960; M. I. El'šin, ibid. **68** (1949), 813–816; MR **11**, 247; N. V. Adamov, Mat. Sb. (N.S.) **23** (**65**) (1948), 187–228; MR **10**, 250; V. A. Greguš, M. 6090

Über das Randwertproblem der n-ten Ordnung in m-Punkten. (Slovak and Russian summaries)

Acta Fac. Natur. Univ. Comenian. **9**, 49–55 (1964).

The author considers the linear operator of the form

$$Ly\equiv p_0(x)y^{(n)}+p_1(x)y^{(n-1)}+\cdots+p_n(x)y$$
$$(n\ge 2,\ p_0(x)\ne 0 \text{ in } \langle a_1,a_m\rangle)$$

with the boundary conditions $\bigcup_i y=0$ $(i=1,\cdots,n)$ prescribed at m distinct points $a_1<a_2<\cdots<a_m$. The $\bigcup_i y$ are linearly independent combinations of $y(a_1),\cdots,y^{(n-1)}(a_1),\ y(a_2),\cdots,y^{(n-1)}(a_2),\cdots,y(a_m),\cdots,y^{(n-1)}(a_m)$. Under the assumption that $u\equiv 0$ is the only solution of the corresponding homogeneous boundary-value problem, the author constructs the so-called particular Green's functions $G_k(x,\xi)$ which represent the generalization of the classical Green's functions. The solution of the nonhomogeneous problem $Ly=r(x)$, $\bigcup_i y=0$ $(i=1,\cdots,n)$ is given by the formula

$$y(x)=\sum_{k=1}^{m-1}\int_{a_k}^{a_{k+1}}G_k(x,\xi)r(\xi)\,d\xi.$$

M. Zlámal (College Park, Md.)

Hukuhara, Masuo 6091

Une propriété de l'application $f(x,y,y',\cdots,y^{(n)})$.

Funkcial. Ekvac. **5** (1963), 135–144.

L'auteur prend pour point de départ le fait suivant: Une fonction $\varphi\in C^n[a,a']$ est déterminée d'une manière unique si l'on donne la dérivée d'ordre n, ainsi que ses valeurs $b_1,\cdots,b_n$ en n points $a_1,\cdots,a_n$ de l'intervalle $[a,a']$; si la suite de fonctions $\varphi_\nu\in C^n[a,a']$ est telle que la suite $\{\varphi_\nu^{(n)}\}$ converge uniformément vers $q(x)$ sur $[a,a']$ et $\{\varphi_\nu(x)\}$ converge vers $b_1,\cdots,b_n$ respectivement pour les valeurs $a_1,\cdots,a_n$ de x, alors la suite $\{\varphi_\nu\}$ converge dans l'espace $C^n[a,a']$. Soit maintenant $f(x,y_0,y_1,\cdots,y_n)$ une fonction sommable par rapport à x, continue en $(y_0,y_1,\cdots,y_n)$ et telle que

$$|f(x,y_0,\cdots,y_n)-f(x,z_0,\cdots,z_n)|\le\sum_{k=0}^{n-1}P_{n-k}(x)|y_k-z_k|,$$

$$\frac{f(x,y_0,\cdots,y_n)-f(x,z_0,\cdots,z_n)}{y_n-z_n}\ge\lambda>0,$$

où $P_k(x)$ sont des fonctions sommables sur $[a,a']$. Supposons de plus $\|P_1\|l+\|P_2\|l^2+\cdots+\|P_n\|l^n<\lambda$ où $\|P_k\|=l^{-1}\int_a^{a'}|P_k(x)|\,dx$, $l=a'-a$. Alors, pour assurer la convergence de la suite $\varphi_\nu\in C^{n-1}[a,a']$ dans cet espace, il suffit que l'on ait la convergence de cette suite en n points de $[a,a']$ et la convergence en moyenne (c'est-à-dire en $L[a,a']$) de la suite $\{f(x,\varphi_\nu(x),\cdots,\varphi_\nu^{(n)}(x))\}$, avec $\varphi_\nu^{(n-1)}$ absolument continues. La fonction limite φ satisfait à

l'équation $f(x, y, y', \cdots, y^{(n)}) = \varphi(x)$, où $\varphi(x)$ est la limite de la suite $\{f(x, \varphi_\nu(x), \cdots, \varphi_\nu^{(n)}(x))\}$ dans $L[a, a']$.

Murphy, E. L.; Good, R. H., Jr. 6092

WKB connection formulas.

J. Math. and Phys. **43** (1964), 251–254.

The authors discuss the WKB connection formulas which relate the WKB approximate solutions of $\psi''(x) + p^2(x)\psi(x) = 0$ on either side of a simple zero of $p^2(x)$. They mention the well-known fact that the connection formulas may be derived by the asymptotic expansion of the uniform approximate solutions in terms of Bessel functions of order $\frac{1}{3}$ (or Airy functions) due to R. E. Langer. They conclude from this derivation that the connection formulas preserve linear combinations of solutions and hence can be used to connect approximate solutions across several successive turning points. These are well-known results.

C. H. Wilcox (Madison, Wis.)

Bellman, Richard 6093

Oscillatory and unimodal properties of solutions of second order linear differential equations.

Boll. Un. Mat. Ital. (3) **19** (1964), 306–310.

Author's summary: "In previous papers [same Boll. (3) **12** (1957), 520–523; MR **19**, 885; ibid. (3) **16** (1961), 164–166; MR **24** #A290] we have shown how to derive fundamental properties of the solutions of

$$u'' + p(x)u = 0$$

directly from the fact that it is the Euler equation associated with the functional

$$J(u) = \int_0^a [u'^2 - p(x)u^2]\,dx.$$

Here we wish to demonstrate a Sturm oscillation theorem and the unimodal property of the solution in analogous fashion, under the assumption that $p(x) > 0$."

Alekperov, N. I. 6094

A boundary-value problem with a complex weight function. (Russian)

Dokl. Akad. Nauk SSSR **159** (1964), 479–481.

Dans l'espace $L^2(-\infty, +\infty)$, on considère l'équation différentielle $-y'' + q(x)y = \lambda p(x)y$, où $q(x)$ et $p(x) = q_1(x) + iq_2(x)$ sont des fonctions sommables sur tout intervalle fini de l'axe réel. L'équation considérée s'écrit sous la forme $Ay = \lambda p(x)y$. Si l'on a $q(x) \geq 1$, l'opérateur A^{-1} est auto-adjoint et positif. En posant $y = A^{-1/2}z$, l'équation devient $z = \lambda Lz$. Supposons de plus que les fonctions $q_1(x)$ et $q_2(x)$ sont non-négatives et bornées et que

$$\lim_{|x|\to\infty} \left\{\frac{q(x)}{|x|^\alpha}\right\} \geq C > 0$$

pour $3\alpha \geq 2$. Alors les "autofonctions" de L associées aux points $\neq 0$ du spectre constituent un système complet dans l'espace des valeurs de L. Dans le cas $q_1(x) > 0$, $q_2(x) > 0$ le système est complet dans $L^2(-\infty, +\infty)$. Par "autofonctions" il faut comprendre les autofonctions au sens habituel ainsi que les fonctions attachés aux autovaleurs multiples dans un sens précisé. Voir aussi le travail de V. B. Lidskiĭ [Trudy Moskov. Mat. Obšč. **9** (1960), 45–79; MR **25** #3984].

C. Corduneanu (Iaşi)

Brauer, Fred 6095

On the completeness of biorthogonal systems.

Michigan Math. J. **11** (1964), 379–383.

In this paper the author obtains a Hilbert space theorem dealing with biorthogonal sequences to combine with the asymptotic estimates to yield a proof of completeness of the eigenfunctions of a non-selfadjoint boundary-value problem. In particular, he states Theorem 1: If $\{\phi_n\}$ is a complete orthonormal sequence, and if $\{x_n\}$, $\{y_n\}$ is a normalized biorthogonal system such that

$$(1) \qquad \sum_{n=1}^\infty \|\phi_n - x_n\|^2 < \infty, \qquad \sum_{n=1}^\infty \|\phi_n - y_n\|^2 < \infty,$$

then the system $\{x_n\}$, $\{y_n\}$ is complete. He then uses this theorem to prove Theorem 2: The eigenfunctions of the boundary-value problem $Lx = \lambda x$, $Ux = 0$, with regular boundary conditions, together with the eigenfunctions of the adjoint problem $L^+y = \lambda y$, $U^+y = 0$, can be chosen so as to form a normalized biorthogonal system that is complete in $L^2(a, b)$.

{The author has communicated to the reviewer that the proof of Theorem 1 must be modified.}

McKelvey, Robert W. 6096

Asymptotic solutions and indefinite boundary value problems.

Asymptotic Solutions of Differential Equations and Their Applications (Proc. Sympos., Math. Res. Center, U.S. Army, Univ. Wisconsin, Madison, Wis., 1964), pp. 109–127. *Wiley, New York*, 1964.

The author considers several differential boundary-value problems, each of which in a certain sense is self-adjoint relative to an indefinite inner product. Pertinent features revealed in each case by asymptotic studies are described, and then there is presented an abstract vector-space setting for the problems which provides an explanation for their common properties. There is pointed out the significance in the abstract setting of some individual features observed in the separate problems, as well as phenomena present in the special cases which as yet are unexplained by any general theory.

Dautov, M. A.; Muratov, L. M. 6097

Asymptotic representation of solutions of a first-order polynomial differential equation. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 4 (41), 61–68.

The authors study a polynomial equation of the form $f(x, y, y') = \sum_{m,n,p} a_{mnp}(x)x^m y^n (y')^p = 0$. They determine some rather complicated conditions under which it is possible to find constants α_1, c_1 such that this equation has a solution of the form $y = c_1x^{\alpha_1} + o(x^{\alpha_1})$.

F. Brauer (Madison, Wis.)

Bureau, F. J. 6098

Differential equations with fixed critical points.

Ann. Mat. Pura Appl. (4) **64** (1964), 229–364.

Consider the differential equation (1) $y' = R(x, y, y')$, where $'$ denotes derivation with respect to the complex variable x and R denotes a rational function in y and y' whose coefficients $a_i(x)$ are analytic in x. The solution $y(x)$ of (1) with initial data x_0, y_0, y_0' is an analytic function whose singularities depend, in general, not only on the singularities of the $a_i(x)$ but also on the initial data y_0, y_0'. When (1) is such that the singularities of $y(x)$ depend only on those of the $a_i(x)$, then it is said to have fixed singularities. In the present paper the author determines all forms of R for which (1) has fixed singularities, using a method that is somehow inspired by the classical work of Painlevé. The results are too lengthy to be given here.

M. M. Peixoto (Providence, R.I.)

Čerdak, B. M. 6099

Some properties of systems of differential equations. (Russian)

Leningrad. Gos. Ped. Inst. Učen. Zap. **238** (1962), 149–156.

The author considers a system of differential equations:

$$(1) \qquad \frac{dy}{dt} = A(t)y + f(t),$$

where $f = (f_1, \cdots, f_n)$ and $A(t) = (a_{ij}(t))$, $i, j = 1, \cdots, n$, is a continuous $n \times n$ matrix. The author examines the conditions which $A(t)$ must satisfy in order that the boundedness of all solutions of (1) for any (continuous bounded) vector $f(t)$ with (2) $f_{k+1}(t) = \cdots = f_n(t) = 0$ implies the boundedness of all solutions of (1) for any continuous bounded vector $f(t)$. Let $B(t)$ be the $(n-k) \times (n-k)$ matrix $B(t) = (a_{ij}(t))$, $i, j = k+1, \cdots, n$, and $C(t)$ the $k \times (n-k)$ matrix $C(t) = (a_{ij}(t))$, $i = 1, \cdots, k$, $j = k+1, \cdots, n$. (I) In order that the boundedness on the positive t-axis of all solutions of (1) for any continuous and bounded vector function f satisfying (2) implies the boundedness on the positive t-axis of all solutions of (1) for any continuous and bounded vector f it is sufficient that the system $dz/dt = B(t)z + g(t)$ have at least one bounded solution for every continuous and bounded vector function $g(t) = (g_{k+1}, \cdots, g_n)$. (II) This condition is also necessary if $C(t) \equiv 0$. (III) Under the hypotheses of (I) and for every solution $x(t)$ of $dx/dt = A(t)x$, an inequality of the form $\|x(t)\| \leq Ne^{-\nu(t-t_0)}\|x(t_0)\|$, $0 \leq t_0 \leq t < +\infty$, always occurs for some constants N and ν. Results of M. G. Kreĭn [Uspehi Mat. Nauk **3** (1948), no. 3 (25), 166–169; MR **10**, 128] are used.

L. Cesari (Ann Arbor, Mich.)

Conti, Roberto 6100

Una relazione di equivalenza tra matrici e sue applicazioni alle equazioni differenziali lineari.

Math. Notae **19** (1964), 93–98.

Let $\mathscr{M}$ be the linear complex space of $n \times n$ matrices, whose elements are complex functions of t, which are continuous in a fixed open interval (α, β), $-\infty \leq \alpha < \beta \leq +\infty$. Let $\mathscr{L}^+$ be the subset of $\mathscr{M}$ of matrices of class $C^1(\alpha, \beta)$, nonsingular, bounded together with their inverse matrices in (γ, β), for any γ such that $\alpha < \gamma < \beta$. Finally, let $\mathscr{F}^+$ be a linear variety of $\mathscr{M}$ such that if $L \in \mathscr{L}^+$ and $F \in \mathscr{F}^+$, then LF and FL also belong to $\mathscr{F}^+$. The author defines $A \in \mathscr{M}$ and $B \in \mathscr{M}$ to be $\mathscr{F}^+$-similar if there exist $L \in L^+$ and $F \in \mathscr{F}^+$ such that

$$\dot{L} + LA - BL = F, \qquad \dot{L} = dL/dt, \; t \in (\alpha, \beta).$$

The author proves that $\mathscr{F}^+$-similarity is an equivalence relation. For particular choices of $\mathscr{F}^+$ the resulting relation has already been considered; for instance, taking $\mathscr{F}^+$ to be the subspace of $\mathscr{M}$ of absolutely integrable matrices in $(\gamma, +\infty)$, $\mathscr{F}^+$-similarity turns out to be t_∞-similarity, and the author gives a new, simple proof of his own previous result [Atti Accad. Naz. Lincei. Rend. Cl. Sci. Fis. Mat. Natur. (8) **19** (1955), 247–250; MR **18**, 483; Riv. Mat. Univ. Parma **8** (1957), 43–47; MR **20** #5322]. The author defines two systems $\dot{x} = A(t)x$ and $\dot{y} = B(t)y$ to be $\mathscr{F}^+$-similar if A and B are $\mathscr{F}^+$-similar, and proves that the linear homogeneous differential systems which are uniformly and asymptotically stable form an equivalence class of F^+-similarity, provided that $\mathscr{F}^+$ is taken to be the subspace of $\mathscr{M}$ such that $F \in \mathscr{F}^+$ if and only if the norm of $F(t)$ tends to zero when $t \to \infty$. {Misprint: If (1) and (2) are correctly written, then they should be $\dot{x} = B(t)x$ and $\dot{y} = A(t)y$.}

A. Dou (Madrid)

Flatto, Leopold 6101

Limit cycle studies for circuits containing one Esaki diode.

J. Math. Anal. Appl. **9** (1964), 360–383.

The author studies the existence of limit cycles of a standard single tunnel diode electrical circuit described by

$$L\dot{i} = E - Ri - v,$$

$$C\dot{v} = i - f(v).$$

It is known [J. Moser, IBM J. Res. Develop. **5** (1961), 226–240; MR **23** #B1614] that $f'/C + R/L > 0$ for all v precludes the existence of limit cycles. This paper deals with the case $f'/C + R/L < 0$ for an interval (v_1, v_2). Let P_1, P_2 denote the two points $(v_1, f(v_1))$, $(v_2, f(v_2))$ and P the singular point whose position depends on E. It is shown that if $f'^2 - (1/R - CR/L)f'' > 0$ $[<0]$ at P_i $(i = 1, 2)$ then an unstable [stable] limit cycle grows out of P as it passes through P_i by varying E. A power series for the generated limit cycle is given.

Halvorsen, Sigbjørn 6102

On the quadratic integrability of solutions of $d^2x/dt^2 + f(t)x = 0$.

Math. Scand. **14** (1964), 111–119.

On a half-open (finite or half-infinite) interval let $f(t)$ and $g(t)$ be real and locally integrable, and possess (possibly) non-integrable singularities at the open end. There are obtained certain comparison theorems for the pair of differential equations (1) $x'' + f(t)x = 0$ and (2) $y'' + g(t)y = 0$. In particular, the author generalizes a result, Theorem 2, p. 513, of R. Bellman [Duke Math. J. **11** (1944), 513–516; MR **6**, 66] and shows that if $|g-f|^{1/2}x \in L^2$ for every solution x of (1), then also $|g-f|^{1/2}y \in L^2$ for every solution y of (2), and (1) and (2) are of the same (Weyl) type, limit-point or limit-circle. In addition, there is derived a condition under which (2) is of the limit-circle type whenever (1) is. Additional limit-circle criteria, together with some results on non-oscillatory equations, are also obtained.

Jean, Michel; Sideriades, Lefteri 6103

Circuits non autonomes du premier ordre.

C. R. Acad. Sci. Paris **256** (1963), 5505–5507.

The content of this note can be described in terms of an example. The equation of a circuit with a nonlinear tube, resistance, capacitance, and a periodic applied voltage is $f(x, y, t) = x + g(y) - F(t) = 0$, where x is charge, $\dot{x} = y$ is current, and $F(t)$ is periodic. This equation defines a surface S in the space (x, y, t). This surface is an integral surface of the system (*) $\dot{x} = y$, $g'(y)\dot{y} = -y + F'(t)$. The curve C_λ obtained by the intersection of S with the plane $t = \lambda$, a constant, is introduced. Projected on the (x, y)-plane, C_λ is an integral curve of (**) $dx/d\tau = y$, $dy/d\tau = -y/g'(y)$. This is an autonomous system (and in this case does not depend on λ) and is related to (*). This relationship is then used, it would appear, to construct geometrically the forced oscillations of the circuit. The method is not clearly explained and its value is dubious.

Leighton, Walter 6104

Erratum: "Behavior of solutions of a linear differential equation of second order."

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 1129.

"In the original article [same Proc. **52** (1964), 830–832; MR **29** #3718] the proof of the theorem is incomplete. The hiatus was discovered just as the article appeared in print. Whether or not the stated theorem is valid remains, at least for the time being, an open question."

Morris, G. R. 6105

Unbounded solutions of a second-order differential equation with non-negative damping.

Contributions to Differential Equations **3** (1964), 421–433.

In the differential equation $\ddot{x} + f(x, \dot{x})\dot{x} + g(x) = p(t)$, with everywhere continuous coefficients, assume that $f(x, y) \geq 0$ and that $g(x) = x$ for all large x, while $p(t)$ is periodic. On the basis of the physical interpretations of such differential equations it is tempting to conjecture that every solution, as well as its derivative, remains bounded as $t \to \infty$, except possibly for certain equations close to linear ones with resonance. The author shows that this is not true. He constructs explicit examples of such equations that possess a one-parameter family of solutions for each of which $|x(t)| + |\dot{x}(t)| \to \infty$ as $t \to \infty$. The equation can even be subjected to the additional restrictions that $f(x, y) \leq \varepsilon$, $|x - g(x)| \leq \varepsilon$, where ε is arbitrarily small. The corresponding linear equation $\ddot{x} + x = p(t)$ does not exhibit resonance. The construction requires a detailed, fairly explicit analysis of several auxiliary simpler differential equations from which the counter-example is pieced together.

W. Wasow (New York)

Munteanu, I. 6106

Sur un cycle limite.

Mathematica (Cluj) **4** (**27**) (1962), 293–307.

Consider the differential equation in the plane

$$\varepsilon \frac{dx}{dt} = h(y) - F(x),$$

$$\frac{dy}{dt} = -\varepsilon g(x),$$

where F, g, and h are odd functions, F has a unique positive root and is negative for small positive x and positive for large positive x, $xg(x) > 0$ for $x \neq 0$, and h is monotone and goes to ∞ with y.

Theorem 1: If $\varepsilon > 0$, this sytem has a unique limit cycle Γ_ε which is orbitally stable. Theorem 2: If F, g, and h satisfy monotonicity conditions on certain intervals, then the limit cycles Γ_ε tend to a simple closed curve Γ_0 as ε tends to 0. The proofs are similar to those for related theorems by earlier authors.

Invariant sets of point-wise mappings. (Russian. Latvian and English summaries)

Latvijas PSR Zinātņu Akad. Vēstis Fiz. Tehn. Zinātņu Sēr. **1964**, no. 3, 31–35.

Let the system $dx/dt = P(x)$ have a closed trajectory γ. Following Liapounov, the equation of first variation associated with γ is closely related to an autonomous equation $dv/ds = Bv$, where v has one less dimension than x. The present paper shows that if none of the "multipliers" associated with γ has absolute value one, then there exists a homeomorphism of $v = 0$ with a cross-section of γ which carries trajectories (or pairs of trajectories) of $dv/ds = Bv$ into sets which are invariant under the transformation induced by the motion of the original system as it goes once around γ. This generalizes a theorem of Hadamard [Bull. Soc. Math. France **29** (1901), 224–228] and others.

On periodic solutions of a certain nonlinear equation.

Prikl. Mat. Meh. **27** (1963), 1107–1110 (*Russian*); *translated as J. Appl. Math. Mech.* **27** (1964), 1699–1704.

The author studies the question of the existence of periodic solutions of the equation

$$\frac{d^2z}{dt^2} - \frac{2e \sin t}{1 + e\cos t}\frac{dz}{dt} + \frac{\mu}{1 + e\cos t}\sin z = \frac{4e \sin t}{1 + e\cos t}$$

$$(0 \leq e < 1)$$

by the method due to L. Cesari [Active Networks and Feedback Systems (Proc. Sympos., New York, 1960), pp. 545–560, Polytechnic Press of Polytechnic Inst. Brooklyn, Brooklyn, New York, 1961].

The author first derives a sufficient condition for the existence of periodic solutions. Then the existence of a periodic solution is proved for the case when $0 \leq \mu \leq 1$ and $e = 0.6$ [cf. V. V. Beleckiĭ, Iskusstvennye Sputniki Zemli No. 3 (1959), 13–31].

Y. Sibuya (Minneapolis, Minn.)

Reid, William T. 6110

Principal solutions of nonoscillatory linear differential systems.

J. Math. Anal. Appl. **9** (1964), 397–423.

The author presents generalizations of previous results obtained by him [Pacific J. Math. **13** (1963), 665–685; MR **27** #4991] on the principal solution at ∞ of a nonoscillatory linear system and the corresponding distinguished solution of the associated Riccati matrix differential equation. Besides replacing the previously required condition of identical normality by the weaker condition that both the given system and its adjoint be nonoscillatory, he includes necessary and sufficient conditions for the existence of a distinguished solution (formerly only a necessary condition was given). Following an extensive treatment of similar considerations for self-adjoint systems is a section containing two theorems on the general reciprocal of a finite matrix.

J. Stuelpnagel (Baltimore, Md.)

Reissig, Rolf 6111

Stabilität und asymptotisches Verhalten dynamischer Systeme. (Russian, English and French summaries)

Wiss. Z. Humboldt-Univ. Berlin Math.-Natur. Reihe **12** (1962/63), 527–532.

The paper is an exposition of some of the methods available for studying the asymptotic behavior of systems described by an n-dimensional differential equation $\dot{x} = F(x, t)$, where x and $F(x, t)$ are n-vectors and $\dot{x} = dx/dt$. The two principal problems discussed are (1) system stability and (2) stability of solutions. By system stability is meant that solutions are defined in the future and perhaps also that they be bounded in the future. For the most part the methods are those of Liapunov and are illustrated by the study of n coupled oscillators, $\ddot{x} + f(x, \dot{x}, t) + g(x) = e(t)$, where again x is an n-vector.

J. P. LaSalle (Providence, R.I.)

Reissig, R. [Reissig, Rolf] 6112

Ein funktionalanalytischer Existenzbeweis für periodische Lösungen.

Monatsb. Deutsch. Akad. Wiss. Berlin **6** (1964), 407–413.

The system (1) $x' = f(x) + p(t)$, where f is Lipschitzian and p is periodic with period ω, is compared with the linear system (2) $x' = Ax + p(t)$, where the eigenvalues of A all have negative real parts. This is done by setting $f(x) = Bx + f_1(x)$, $A = B + A_1$ and considering the system (3) $x' - Ax = \mu[f_1(x) - A_1x] + p(t)$ for $0 \leq \mu \leq 1$, which reduces to (1) when $\mu = 1$ and to (2) when $\mu = 0$. It is assumed that all solutions of (3) are bounded independently of μ. The author uses a Lyapunov function to deduce the existence of a periodic solution of (2). He then uses a fixed-point theorem for the Banach space of periodic functions to deduce the existence of a periodic solution of (3) for $0 < \mu \leq 1$ and hence the existence of a periodic solution of (1).

Sansone, G. 6113

L'équation

$$\ddot{\theta} + f(\theta, \alpha)h(\dot{\theta}) = g(\theta) + p(t).$$

J. Math. Pures Appl. (9) **43** (1964), 149–175.

Continuing his research on "pendulum-type" equations [e.g., same J. (9) **40** (1961), 363–384; MR **25** #3226], the author now considers the solutions of the equation of the title, with forcing term $p(t)$. Under rather weak conditions on f, h, g, p, too variable to be reported in detail here, but much weaker than those considered by Seifert [Ann. of Math. (2) **67** (1958), 83–89; MR **19**, 960; ibid. (2) **69** (1959), 75–87; MR **20** #7132], he establishes the existence of a solution defined for all future time, the existence of a region in the phase plane, bounded by a smooth Jordan curve, such that any solution that touches it cannot leave (and every such solution is defined for all future time), and, for period p, the existence of a periodic solution of the equation and, under somewhat stronger conditions, the asymptotic stability of the periodic solution.

On some aspects of non-linear oscillations.

Studies in mathematical analysis and related topics, pp. 245–255. *Stanford Univ. Press, Stanford, Calif.*, 1962.

The author considers the phase portrait of non-linear differential equations. The bifurcation points of Liénard's equations are obtained by studying a stroboscopic system, and its phase portrait is studied. He indicates methods of studying the phase portrait of several other autonomous equations. Finally, it is shown how his method can be applied to certain non-autonomous systems. *B. Bernstein* (Washington, D.C.)

Bogdanov, Ju. S. 6119

An application of generalized characteristic numbers for studying the stability of a stationary point. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 9–12.

The author considers a system of the form (1) $dx/dt=f(x)$, x an n-vector, f Lipschitzian around the origin, and the origin an isolated equilibrium point of (1). The generalized characteristic numbers in the title are defined in terms of two scalar functions v and d, where among other assumptions, the level surfaces of v fill out a neighborhood of 0, and d is very nearly a metric, except for the condition $d(\gamma_1,\gamma_2)=-d(\gamma_2,\gamma_1)$ for γ_1,γ_2 positive. Given the functions v and d, the author defines two types of generalized characteristic numbers, and shows that these give necessary and sufficient conditions for either the instability or the asymptotic stability of the origin. The characteristic numbers of Lyapunov are given by choosing $v(x)=\|x\|$, $d(\gamma_1,\gamma_2)=\ln(\gamma_1/\gamma_2)$. For linear systems, both generalized characteristic numbers of Bogdanov (with the above choices of v and d) coincide with the characteristic numbers of Lyapunov. For non-linear systems, this is no longer true, and the author determines their relationship in this case as well. *A. Stokes* (Washington, D.C.)

Brayton, R. K.; Miranker, W. L. 6120

A stability theory for nonlinear mixed initial boundary value problems.

Arch. Rational Mech. Anal. **17** (1964), 358–376.

The authors envisage a generalization to certain mixed initial-boundary-value problems in partial differential equations of the criterion for global asymptotic stability of Ljapunov and its converse, proved by Massera [Ann. of Math. (2) **64** (1956), 182–206; MR **18**, 42]. For this purpose, they consider, with every vector-valued function $u(t,x)$ defined in the x-interval $[0,1]$, the vector $[u]$, consisting of three blocks, the first being u itself, the second $u(t,0)$, and the third $u(t,1)$, and analyse equations which may be written in the form $J(u)[u_t]=P_{[u]}$, where J is a diagonal block matrix and P is a functional of the general form $\int_0^1 F(u,u_x)\,dx+\varphi(u)|_{x=0}+\psi(u)|_{x=1}$. They establish conditions under which this equation represents a dynamical system and examine the existence of appropriate Ljapunov functionals in several generic examples. The details cannot be reproduced here. An important application concerns networks with non-linear elements and transmission lines. *J. J. Schäffer* (Pittsburgh, Pa.)

A sketch, not very clear to the reviewer, of a general criterion for the existence and asymptotic stability of a periodic solution of a periodic differential equation. {In Section 3.2, the equation should be $\ddot{x}+F(\dot{x})+x=p(t)$.} *J. J. Schäffer* (Pittsburgh, Pa.)

Segal, Martin 6122

Stability problems for systems of linear differential equations.

Comm. Pure Appl. Math. **17** (1964), 401–414.

The author considers pairs (T,Y) of matrix-valued functions of a real variable t, T periodic of fixed period w, related by $Y'=TY$, $Y(0)=I$. The pair is stable if the powers of $Y(w)$ are bounded, strongly stable if every neighbouring pair—in the obvious sense—is stable. If A is a fixed symmetric matrix, $G(A)$ is the group of invertible matrices Z such that $Z'AZ=A$. $D(A,w)$ is the set of pairs, in the above-defined sense, such that the values of Y are in $G(A)$ (this implies $T=A^{-1}H$, with H skew-valued and periodic); strong stability is now to be understood with respect to neighbouring pairs in $D(A,w)$. Theorem: (T,Y) in $D(A,w)$ is strongly stable if and only if $Y(w)$ is of definite type with respect to A, i.e., A is definite on the eigenspaces of $Y(w)$. The set of such strongly stable pairs turns out to be open. The author then determines its connected components. Similar problems for skew A were studied by Moser [same Comm. **11** (1958), 81–114; MR **20** #3354] and Gel'fand and Lidskiĭ [Uspehi Mat. Nauk **10** (1955), no. 1 (63), 3–40; MR **17**, 482; Amer. Math. Soc. Transl. (2) **8** (1958), 143–181; MR **19**, 960]. *J. J. Schäffer* (Pittsburgh, Pa.)

Ezeilo, J. O. C. 6124

A boundedness theorem for some non-linear differential equations of the third order.

J. London Math. Soc. **37** (1962), 469–474.

Verfasser behandelt die Differentialgleichung $x''' + f(x, x')x'' + g(x') + h(x) = p(t)$, wobei die Funktionen f, f_x, h', p für alle Werte ihrer Argumente stetig sein sollen. Folgender Satz wird aufgestellt: (a) Es sei $g(0) = 0$, und es gebe positive Konstanten δ_0, δ_1, so daß $g(y)/y \geq \delta_1$ für $y \neq 0$ und $f(x, y) \geq \delta_0$ für alle x, y; (b) $h(x) \operatorname{sgn} x \geq 0$ für $|x| \geq 1$; (c) $h'(x) \leq c$ für alle x mit einer Konstante $0 < c < \delta_0\delta_1$; (d) $yf_x(x, y) \leq \Delta$ für alle x, y und eine Konstante $0 < \Delta < (\delta_0\delta_1 - c)/\delta_0$. Unter den Bedingungen (a) bis (d) existiert die Lösung $x(t)$ mit den Anfangswerten $x(0) = x_0$, $x'(0) = y_0$, $x''(0) = z_0$ für $t \geq 0$ und genügt den Abschätzungen $H(x(t)) = \int_0^{x(t)} h(\xi)\, d\xi \leq K_0\Phi(t)$, $[x'(t)]^2 \leq K_0\Phi(t)$, $[x''(t)]^2 \leq K_0\Phi(t)$; darin ist K_0 eine von den Funktionen f, g, h und den Anfangswerten x_0, y_0, z_0 abhängige Konstante und $\Phi(t) = [1 + \int_0^t \{|p(\tau)|\}^{2(1-\lambda)}\, d\tau]^{1/(1-\lambda)}$, $0 \leq \lambda \leq \frac{1}{2}$. Hat man $H(x) \to \infty$ für $|x| \to \infty$ sowie $\int_0^\infty \{|p(\tau)|\}^{2(1-\lambda)}\, d\tau < \infty$, so gibt es eine Konstante $K_1 = K_1(f, g, h, p; x_0, y_0, z_0)$, mit der man für $t \geq 0$ abschätzen kann: $|x(t)| \leq K_1$, $|x'(t)| \leq K_1$, $|x''(t)| \leq K_1$. Zum Beweis des Satzes bildet der Verfasser eine Ljapunovsche Funktion $V(x, y, z)$: $2V = 2H(x) + \alpha\{2\int_0^y g(\xi)\, d\xi + z^2\} + 2\alpha y h(x) + 2\int_0^y \eta f(x, \eta)\, d\eta + 2yz$, wo $\alpha = \varepsilon + 1/\delta_0$ und $\varepsilon > 0$ eine passend gewählte Zahl ist, und schätzt ihren Verlauf längs der betrachteten Lösung $x(t)$ ab, wobei $y = x'(t)$ und $z = x''(t)$ zu setzen ist (Überführung der Differentialgleichung in ein äquivalentes System von Gleichungen). *R. Reissig* (Zbl 108, 89)

Čičkin, E. S. 6125

On the non-oscillation of solutions of non-linear differential equations of third and fourth order. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1959**, no. 5 (12), 219–221.

Soit l'équation (E) $y^{(n)} = f(x, y, y', \cdots, y^{(n-1)})$ dans laquelle f est continue pour $a \leq x \leq b$, $a_k \leq y^{(k)} \leq b_k$, $k = 0, 1, \cdots, n-1$, et telle que par tout point du domaine de définition il passe une seule solution du problème de Cauchy. L'intervalle $[a, c) \subset [a, b]$ est (par définition) un intervalle de non-oscillation de l'équation (E) si la différence de deux solutions arbitraires de (E) admet tout au plus $n-1$ zéros sur $[a, c)$. Si l'on a $q(x) \leq \partial f/\partial y \leq 0$, où $q(x)$ est continue sur $[a, b]$, alors un intervalle de non-oscillation pour l'équation $v^{(n)} = q(x)v$ est aussi un intervalle de non-oscillation pour (E). Pour $n = 3, 4$, on obtient pour l'équation linéaire des conditions de non-oscillation à l'aide d'une fonction associée d'une manière convenable à cette équation. *C. Corduneanu* (Iași)

Geraščenko, E. I. 6126

On the degree of stability of non-linear systems in a moving regime. (Russian)

Izv. Akad. Nauk SSSR Tehn. Kibernet. **1964**, no. 2, 114–120.

The characteristic equation of the system is $p_r(\lambda) = \lambda^n + c_1(r)\lambda^{n-1} + \cdots + c_n(r) = 0$, where $c_{k+1} = rc_k(r) + a_{k+1}$, $c_0 = 1$ and $a_1, \cdots, a_n$ are given. Thus the coefficients can be varied with constraints on the allowable values of r. The measure $\delta(r)$ of the degree of stability is $\delta(r) = \max\{\alpha_1(r), \cdots, \alpha_n(r)\}$, where $\alpha_j(r)$ denotes the real part of the jth characteristic root. An optimal choice of r is one that minimizes $\delta(r)$. Necessary conditions for minima of $\delta(r)$ are given, and their application is illustrated by an example with $n = 3$. The reason things work out well is that $(\lambda - r)p_r(\lambda) = f_n(\lambda) - f_n(r)$, where $f_n(r) = rc_n(r) = r^{n+1} + a_1r^n + \cdots + a_nr$, and the conditions are in terms of the polynomial $f_n(\lambda)$ and its derivatives. *J. P. LaSalle* (Providence, R.I.)

Olech, Czesław 6127

Global phase-portrait of a plane autonomous system.

Ann. Inst. Fourier (Grenoble) **14** (1964), *fasc.* 1, 87–97.

Consider the autonomous system defined on the plane R^2, (1) $dx/dt = f(x)$, where $x = (x_1, x_2)$, $f = (f_1, f_2)$, and it is assumed that $\operatorname{div} f(x) = \partial f_1/\partial x_1 + \partial f_2/\partial x_2 \leq 0$ on R^2. Among others, the following results about the behaviour of trajectories of (1) are given: (i) If a non-singular trajectory I of (1) is such that its α-limit set $\alpha(I) \neq \varnothing$, then either I is a closed orbit, or else $\alpha(I)$ is composed of singular points; (ii) If the singular points of (1) are isolated, then they are either points of attraction, centers or else generalized (in a certain sense) saddle points. *M. M. Peixoto* (Providence, R.I.)

Ronsmans, P. 6128

Sur la stabilité et l'index des singularités multiples d'un système différentiel autonome.

Acad. Roy. Belg. Bull. Cl. Sci. (5) **50** (1964), 142–173.

From the author's summary: "The system considered is of the type

$$\frac{dx}{dt} = A(x, y), \qquad \frac{dy}{dt} = B(x, y).$$

Simple singularities of this system are always totally stable or totally unstable. Semi-stability appears with multiple singularities. The notion of conditional stability is applied to the study of singular points, and a measure is associated with the stability of the corresponding equilibrium states. The notion of the index, in the sense of Poincaré, is extended to singularities of arbitrary order. Several mathematical examples are studied, and the results are verified by analog computer. Finally, the theory is applied to the study of an electronic circuit." *F. Brauer* (Madison, Wis.)

Lakshmikantham, V. 6129

Differential inequalities and extension of Lyapunov's method.

Proc. Cambridge Philos. Soc. **60** (1964), 891–895.

The author continues his study of differential inequalities which he has previously used in a series of papers to study stability properties of solutions of differential equations. Here he studies the stability properties of solutions of a differential inequality of the form $|x' - f(t, x)| \leq w_1(t, d(x, M))$, where M is a non-empty subset of R^n,

$d(x, M) = \inf_{a \in M} |x-a|$, and $w_1(t, r)$ is continuous for $0 \leq t < \infty$, $r > 0$. The methods and results are analogous to those for differential equations.

Salvadori, Luigi 6130

Sulla stabilità asintotica delle posizioni d'equilibrio di un sistema olonomo in presenza di forze dissipative anche non lineari. (English summary)

Rend. Accad. Sci. Fis. Mat. Napoli (4) **30** (1963), 145–152.

The author considers a holonomic autonomous mechanical system, subject to a system of conservative forces of total potential energy U and a system of dissipative forces with Lagrangian components $Q_i(q, \dot{q})$. A configuration is considered for which U has a minimum (hence the system, even without the dissipative forces, has a stable equilibrium there) and actually the matrix of second derivatives of U is positive. The author generalizes a result of Četaev [*Stability of motion. Papers on analytical mechanics* (Russian), Izdat. Akad. Nauk SSSR, Moscow, 1962; MR **28** #1358; English transl., Pergamon, Oxford, 1961] by showing that the addition of the dissipative forces ensures that the equilibrium is asymptotically stable (and hence totally stable) even if these dissipative forces are of the form $Q_i = Q_i^* + \eta_i$, where $Q_i^* = Q_i^*(\dot{q})$ is homogeneous of some degree $s \geq 1$ (with constant coefficients) in the $\dot{q}$ and such that the form $\sum_i Q_i^* \dot{q}_i$ is negative definite, and the $\eta_i(q, \dot{q})$ are small of order $> s$ for states near the state of rest at the considered configuration. The proof makes ingenious use of Ljapunov's criterion for asymptotic stability.

Stepanov, S. Ja. 6132

On the stability of dissipative systems. (Russian. English summary)

Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, *no.* 4, 59–66.

Consider a Lagrangian system with generalized coordinates $q_1, \cdots, q_n$, with $q_{k+1}, \cdots, q_n$ cyclic, and with conservative forces F_i and other forces of a dissipative type derived from a definite quadratic form in the $\dot{q}_i$ with coefficients depending upon the q_i. For the F_i constant, G. K. Požarickiĭ [Prikl. Mat. Meh. **21** (1957), 503–512; MR **19**, 1100] derived necessary and sufficient conditions for the stability of those motions characterized by $q_i = \text{const}$, $i = 1, 2, \cdots, k$, $\dot{q}_i = \text{const}$, $i = k+1, \cdots, n$. The present author discusses the stability of the same motions when the F_i are allowed to vary with the disturbed motion but reduce to constants at the undisturbed motion. An application is given for the motion of a gyroscope. The results are obtained by the construction of an appropriate Lyapunov function.

Brullinskaja, N. N. 6133

Limit cycles of the equations of motion of a rigid body and for the Galerkin equations of hydrodynamics. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1017–1020.

The object of study is a certain class of systems of nonlinear differential equations involving a parameter ν. This class is of great interest because it includes the Galerkin approximations to the time-dependent Navier-Stokes system of partial differential equations governing viscous fluid motion. Also, when the order is 3, the system considered represents the equations of damped motion of a rigid body. In the first case ν represents the viscosity; in the second, a damping factor. The author states several results about the behavior of the solution as the independent variable $t \to \infty$. For example, although for large ν there exists a stable equilibrium point which all solutions approach, there is a critical value ν_{cr} such that stable or unstable limit cycles arise as ν passes through ν_{cr}, provided the coefficients of the system satisfy a certain inequality. These results are what one might expect of solutions of the Navier-Stokes system. It is indicated that the proofs (not given) are based largely on the author's previous note [same Dokl. **139** (1961), 9–12; MR **26**, 5212].

Likova, O. B. [Lykova, O. B.] 6135

On the behaviour of the solutions of a system of $n+m$ differential equations in the neighbourhood of an equilibrium point. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 569–573.

The author considers the following system (1) $dx/dt = X(y) + \varepsilon X^*(t, x, y)$, $dy/dt = \varepsilon Y(t, x, y)$, where ε is a small parameter, x, y are n- and m-vectors, respectively, X^* and Y are periodic in t of period 2π, and in addition, the following assumptions hold: Let $Y_0(x, y)$ be the time-average of $Y(t, x, y)$, then assume $Y_0(0, 0) = 0$, $(\partial Y_0/\partial x)(0, 0) \neq 0$, and each of the matrices $X(0)$ and $(\partial Y_0/\partial y)(0, 0)$ has a pair of purely imaginary (non-zero) eigenvalues, with the remaining $n-2$ and $m-2$ eigenvalues with

negative real parts, respectively. Then the author asserts that there exists, for ε sufficiently small, an asymptotically stable manifold S of (1) in a neighborhood of $x=y=0$, which is described by two n- and m-vector-valued functions of t, ε, and four real variables, periodic in t of period 2π, Lipschitzian in the last four variables. No proofs are given, merely an indication of the existence of transformations, using the method of averaging, which allow the above results to be deduced. *A. Stokes* (Washington, D.C.)

Les systèmes dynamiques abstraits.

Ann. Inst. Fourier (Grenoble) **12** (1963), *fasc.* 2, 191–202.

A nonconservative dynamical system may be defined by means of a two-form Ω on the tangent sphere bundle of the underlying space-time, such that $\Omega=d(\dot{d}L)+S$ with S a semi-basic two-form called the force tensor [the author, same Ann. **12** (1962), 1–124]. "Semi-basic" means that at each point the form is equal to a form induced from the base space, and $\dot{d}$ is the obvious exterior derivative that takes semi-basic forms into semi-basic forms. In this paper it is proved that, given a two-form Ω on the sphere bundle, its pull-back to the bundle of nonzero tangent vectors can be written in the above form if and only if $d\Omega=0$. In making this statement, we use the fact that $\dot{d}$ may be extended so that it operates on any form.

B. L. Reinhart (College Park, Md.)

Korobeinik, Ju. F. 6137

Entire solutions of a differential equation of infinite order. (Russian. Lithuanian and English summaries)

Litovsk. Mat. Sb. **4** (1964), 203–227.

From the author's summary: "The author considers entire solutions of the differential equations of infinite order of the form

$$(1)\quad y(x)+\sum_{k=1}^{\infty}P_k(x)y^{(k)}(x)=f(x),\qquad P_k(x)=\sum_{s=0}^{N_k}a_s^kx^s,$$

where

$$\sup_{k\geq 1}\frac{N_k}{k}=\alpha<1,\qquad \limsup_{k\to\infty}\sqrt[k]{\left(\sup_{0\leq s\leq N_k}|a_s^k|\right)}<\infty.$$

The author obtains a theorem on the existence and uniqueness of solutions of (1) in the class of entire functions $[1-\alpha,\sigma]$, $\sigma<\infty$, and indicates a method of approximating such solutions. The asymptotic behavior of such entire solutions is also investigated, and a lower bound for the entire transcendental solutions of the homogeneous equation is obtained."

A. Stokes (Washington, D.C.)

Korobeinik, Ju. F. 6138

Entire analytic solutions of equations of infinite order with polynomial coefficients. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1031–1034.

The author continues his investigations of equations of the form (1) $\sum_{k=0}^{\infty}P_k(x)y^{(k)}(x)=f(x)$. In the paper the author announces some results which extend some of his earlier results. However, the hypotheses and conclusions of the five theorems given are too complicated to state here. In addition to announcing these new results, the author makes a valuable contribution by providing an extensive bibliography (14 references) of his own work and related work by other authors, with a brief expository account of the development of the theory of such equations. At the end of the paper, the author gives an application of the theory developed for equations of the form (1) to the functional equation (2) $y(x+a\sqrt{x})+y(x-a\sqrt{x})=f(x)$.

A. Stokes (Washington, D.C.)

Valeev, K. G. 6139

Linear differential equations with a time lag depending linearly on the argument. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 290–300.

The author applies Laplace transform methods to the linear functional-differential system (generally of neutral type)

$$(1)\qquad \sum_{q=0}^{l}\sum_{k=0}^{n}A_{qk}\frac{d^kY}{dt^k}(\alpha_{qk}t-\beta_{qk})=\sum_{j=1}^{\lambda}C_jt^{\nu_j}e^{\omega_jt},$$

where $Y(t)$ is the unknown vector, the A_{qk} are constant matrices, $\alpha_{0k}=1,\beta_{0k}=0,0<\alpha_{qk}<1,\beta_{qk}\geq 0$ (for $q=1,\cdots,l$), $A_{0n}=E$, $\sum_{q=1}^{l}|A_{qn}(\alpha_{qn})^{-n-1}|<1$, the C_j are constant vectors, the ν_j are non-negative integers, and the ω_j are complex numbers. Specifying $d^kY(0)/dt^k=Y_0^{(k)}$ for $k=0,\cdots,n-1$ and $d^kY(t)/dt^k=\Theta^{(k)}(t)$ for $-\beta\leq t<0$, $k=0,\cdots,n$, where the $\Theta^{(k)}(t)$ satisfy Dirichlet conditions, the author obtains infinite-series expansions for the solution of (1) for $t>0$. Special results are obtained in case each $\beta_{qk}=0$, and the case of complex α_{qk} is considered. A number of examples of delay-differential systems ($A_{qn}=0$ for $q=1,\cdots,l$) are given, including two in which the results are applied to other special forms of such equations:

$$v'(x)+\mu e^xv(x)=\gamma e^xv(x-\beta)\ \text{ and }\ zv'(z)+\mu v(z)=\gamma v(\sqrt{z}).$$

Einige Bemerkungen zur Differentialgleichung $X'(t)=P(t)X(t)$ für Operatorfunktionen.

Wiss. Z. Humboldt-Univ. Berlin Math.-Natur. Reihe **13** (1964), 181.

From the author's summary: "$P(t)=A+V(t)$ ($t\in\Omega$, Ω die Gesamtheit der reellen Zahlen) sei eine Operatorfunktion abgeschlossener Operatoren eines Banachschen Raumes $\mathfrak{H}$, A sei abgeschlossen und unbeschränkt mit dem Definitionsbereich $\mathfrak{D}_A$, der dicht in $\mathfrak{H}$ liegt, es gebe Zahlen $M>0$, $\omega\geq 0$, so daß $\|R(\lambda,A)^n\|\leq M(|\lambda|-\omega)^{-n}$ gilt für alle $n=1,2,\cdots$, $V(t)$ sei beschränkt für jedes t und in t stark stetig, für $x\in\mathfrak{D}_A$ sei $V(t)x\in\mathfrak{D}_A$ für jedes t, $V(t)$ sei als Operator des Banachschen Raumes $\mathfrak{D}_A$ mit der Norm

$$[x]=\|x\|+\|Ax\|$$

beschränkt für jedes t, und für jedes $x\in\mathfrak{D}_A$ sei die Funktion $V(t)x$ stark stetig in t bezüglich [ ]. Dann gibt es eine in $\Omega\times\Omega$ stark stetige Operatorfunktion $X(t,t_0)$, die auf $\mathfrak{D}_A$ starke partielle Ableitungen nach t und t_0 besitzt mit den weiteren Eigenschaften $X(t_0,t_0)=I$ und $X(t,t_0)x\in\mathfrak{D}_A$, falls $x\in\mathfrak{D}_A$, die bezüglich t eine Lösung von $X'(t)=P(t)X(t)$ und bezüglich t_0 eine Lösung von $Y'(t)=-Y(t)P(t)$ ist. $X(t,t_0)$ ist auch die einzige stark stetige Lösung der beiden Differentialgleichungen mit den angegebenen Eigenschaften."

Santagati, Giuseppe 6141

Problemi quasi lineari negli spazi di Banach. Unicità e dipendenza continua della soluzione dai dati.

Matematiche (Catania) **18** (1963), 15–39.

Let $x(t)$, $\mathfrak{x}(t)$ be functions defined on the closed interval $\Delta=[a,b]$ and taking values in the Banach spaces $\mathfrak{B}_1$, $\mathfrak{B}_2$, respectively. Let X and $\mathfrak{X}$ denote the spaces of functions $x(t)$ and $\mathfrak{x}(t)$ with norms $\|x\|_X=\sup_\Delta\|x(t)\|_{\mathfrak{B}_1}$, $\|\mathfrak{x}\|=\sup_\Delta\|\mathfrak{x}(t)\|_{\mathfrak{B}_2}$, respectively. $\tilde{\mathfrak{B}}_1$ is the space of endomorphisms A on $\mathfrak{B}_1$ with the usual norm $\|A\|_{\tilde{\mathfrak{B}}_1}=\sup_{\|u\|\le 1}\|Au\|_{\mathfrak{B}_1}$. Let $A(t)$ be a mapping from Δ into $\tilde{\mathfrak{B}}_1$, $g(t,u)$ a mapping from $\Delta\times\mathfrak{B}_1$ into $\mathfrak{B}_1$, $\mathscr{L}$ a linear continuous map of X into $\mathfrak{X}$ and $\mathscr{K}$ a continuous map of X into $\mathfrak{X}$. The author considers an equation (E) $\dot{x}=A(t)x+g(t,x)$ with auxiliary condition (C) $\mathscr{L}x=\mathscr{K}x$. A solution of (E), (C) is an element x in X which is absolutely continuous and satisfies (E), (C) for almost every value of t in Δ. A special case of this problem in which the auxiliary condition (C) is replaced by (C′) $\mathscr{L}x=\mathfrak{x}$, $\mathfrak{x}$ being an element of $\mathfrak{X}$, has been studied by Pulvirenti [Matematiche (Catania) **15** (1960), 98–107; MR **25** #5257] in connection with the existence question. In this paper, the author proves the uniqueness (Theorem 1) and the continuous dependence (Theorems 3–6) of the solution on the data $\mathscr{L}$, $A(t)$, $\mathscr{K}$, and $g(t,u)$, as well as the existence. In addition to the conditions on $A(t)$, $g(t,u)$ and $\mathscr{L}$, introduced by Pulvirenti, several more assumptions (Lipschitz continuity of g and $\mathscr{K}$, boundedness of $\|\mathscr{K}(X)\|_{\mathfrak{X}}$, etc.) are made.

Valikov, K. V. 6142

Some criteria for stability of motion in Hilbert space. (Russian)

Uspehi Mat. Nauk **19** (1964), *no.* 4 (118), 179–184.

The author considers an equation of the form (1) $dx/dt=F(x,x,t)+f(x,t)$, where $F(x,y,t)$ and $f(x,t)$ are defined on a ball B centered at the origin in some Hilbert space H, $t\geq 0$, with (2) $F(x,0,t)\equiv 0$ and $\|f(x,t)\|\leq\gamma\|x\|$ for all $t\geq 0$, $x\in B$, $\gamma>0$. Further, assume F has a Gâteaux differential F defined on H, $\delta F(x,y,t;h)=S(x,y,t)h$, S a bounded linear operator for $x,y\in B$, $t\geq 0$. The author gives two conditions sufficient for the origin in (1) to be exponentially uniformly asymptotically stable for γ in (2) sufficiently small, namely: (i) $\lim_{x,y\to 0,t\to\infty}S(x,y,t)=S_0$ exists, where S_0 is a bounded operator with its spectrum in the left half-plane, or (ii) there exists a positive self-adjoint operator B such that the operator $G=BS(x,y,t)+S^*(x,y,t)B$ satisfies the condition $R(\lambda)\leq -\nu$, $\nu>0$, for all $x,y\in B$, $t\geq 0$. Here S^* denotes the adjoint of S.

Fuglede, Bent 6143

★Extremal length and closed extensions of partial differential operators.

Jul. Gjellerups Boghandel, Copenhagen, 1960. 82 *pp.*

This work is divided into two parts. In the first it is shown that three different L^p extensions of a first-order system of partial operators are actually the same extension. The second part is devoted to generalized derivation of exterior differential forms locally of class L^p. An essential feature of the paper is the idea of p-exceptional system of surfaces, which also appears in the author's paper [Acta Math. **98** (1957), 171–219; MR **20** #4187].

Let $1\leq p<\infty$, $\Omega\subset R^n$ be open, $D_\nu=\partial/\partial x_\nu$, and for each $u=(u_1,\cdots,u_s)$ of class $C^1(\Omega)$ let

$$Pu=\sum_{\nu=1}^{n}D_\nu(A_\nu u)+Au.$$

Let $\bar{P}$ and P^w denote, respectively, the L^p-closure and weak closure of P. Using a method of Deny and Lions [Ann. Inst. Fourier (Grenoble) **5** (1953/54), 305–370; MR **17**, 646] it is shown that the condition $\bar{P}u=v$ is purely local. Using Friedrich's mollifiers it is then shown that $\bar{P}=P^w$. A bounded open subset G of R^n is called a Green's set if (roughly speaking) the boundary Γ of G is regular enough that a Gauss-Green identity holds. The precise condition imposed on G is equivalent to the assumption that G is an open set of finite perimeter in the sense of De Giorgi [Ricerche Mat. **4** (1955), 95–113; MR **17**, 596]. A system $\mathbf{E}$ of Green's sets is called p-exceptional if there exists a non-negative Baire function $f\in L^p(R^n)$ such that $\int_\Gamma f\,d\sigma=+\infty$ for every $G\in\mathbf{E}$. The flux extension P^f of P has the property that if u,v are of class $L^p(\Omega)$, then $P^fu=v$ if and only if

$$\int_\Gamma\sum_\nu A_\nu ue_\nu\,d\sigma+\int_G Au\,dx=\int_G v\,dx$$

except for some p-exceptional system of Green's sets G with $G\cup\Gamma\subset\Omega$. Here $e(x)$ denotes the exterior unit normal at x. It is proved that $\bar{P}=P^f$.

In the second part, the L^p-closure $\bar{d}$ of the exterior differential d is considered, and the notion of p-exceptional system $\mathbf{E}$ of class C^1 singular chains is defined. Let u and v be differential forms locally of class $L^p(\Omega)$, of respective degrees $k-1$ and k. Then $\bar{d}u=v$ if and only if Stokes' formula holds for every k-chain not in some p-exceptional system. Periods of closed forms locally of class $L^p(\Omega)$ are then defined, and the appropriate version of De Rham's theorem is proved.

Manninen, Jouko 6144

Über das Existenzgebiet von integralen partieller Differentialgleichungen erster Ordnung.

Ann. Acad. Sci. Fenn. Ser. A I No. 332 (1963), 16 *pp.*

The author gives a practical and efficient estimate for the largest sphere (or polycylinder) inside of which there exists the solution of the Cauchy problem for a system of implicit partial differential equations of first order with one dependent variable. Two rather interesting lemmas (or special cases) concern implicit functions and ordinary differential equations. The notation is that of F. and R. Nevanlinna [*Absolute Analysis*, Springer, Berlin, 1959; MR **22** #12176]; see also the author [Ann. Acad. Sci. Fenn. Ser. A I No. 283 (1960); MR **24** #A319]. The results are too complicated to be stated here.

G. Hufford (Boulder, Colo.)

Schlissel, Arthur 6145

The asymptotic behavior with respect to time of the generalized solution of a first order quasi-linear equation with particular initial values.

J. Math. Anal. Appl. **9** (1964), 356–359.

Let $u_0(x)$ be a real function on the real line such that $u_0(x) = u_+ + o(x^{-1})$ as $x \to \infty$ and such that $K_1 = \int_{-\infty}^0 (u_0(x) - u_-)\,dx$ and $K_2 = \int_0^\infty (u_0(x) - u_+)\,dx$ exist. Let $f''(u) > 0$, let $G(\tau) = \max_u (u\tau - f(u))$ be the conjugate function of f and let the maximum occur when $u = b(t)$. Let $y_0 = y_0(x, t)$ minimize $\int_0^y u_0(x)\,dx + tG((x-y)/t)$. Then $u = b((x-y_0)/t)$ is an appropriate solution of $u_t + f_x(u) = 0$ with initial data $u_0(x)$. It is shown that as t tends to ∞, u tends to u_- and u_+ to the left and to the right of an asymptotic shock line $(u_+ - u_-)x = (f(u_+) - f(u_-))t - K_1 - K_2$. The same result has been obtained by Il'in and Oleĭnik [Mat. Sb. (N.S.) **51** (**93**) (1960), 191–216; MR **22** #11222]. *L. Gårding* (Lund)

Wu, Zhuo-qun [Wu, Cho-chün] 6146

On the existence and uniqueness of the generalized solutions of the Cauchy problem for quasilinear equations of first order without convexity conditions.

Acta Math. Sinica **13** (1963), 515–530 (*Chinese*); *translated as Chinese Math.* **4** (1964), 561–577.

Existence and uniqueness questions for discontinuous solutions of the Cauchy problem

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0, \qquad 0 \le t \le T,$$

$$u|_{t=0} = u_0(x), \qquad -\infty < x < \infty,$$

are considered. The function $f(u)$ is assumed twice continuously differentiable and the solution $u(x, t)$ is required to satisfy

$$\frac{f(v) - f(u(t, x(t)-0))}{v - u(t, x(t)-0)} \ge \frac{f(u(t, x(t)+0)) - f(u(t, x(t)-0))}{u(t, x(t)+0) - u(t, x(t)-0)}$$

along any curve $x(t)$ of discontinuity. This condition is related to one suggested by Gel'fand [Uspehi Mat. Nauk **14** (1959), no. 2 (86), 87–158; MR **22** #1736; Amer. Math. Soc. Transl. (2) **29** (1963), 295–381; MR **27** #3921]. The author proves a uniqueness theorem which generalizes previous work of Oleĭnik [Uspehi Mat. Nauk **14** (1959), no. 2 (86), 165–170; MR **22** #8178; Amer. Math. Soc. Transl. (2) **33** (1963), 285–290]. Applying a method due to Douglis [Comm. Pure Appl. Math. **12** (1959), 87–112; MR **21** #3650], he proves existence in the large for weak solutions under assumptions on $f(u)$ and $u_0(x)$. The class of functions in which existence is proved is larger than the class for which uniqueness is proved. *M. Schechter* (New York)

Bouligand, G. 6147

Sur les surfaces intégrales d'équations aux dérivées partielles d'ordre 1 et leurs arêtes de rebroussement (dans un R^3).

J. Math. Pures Appl. (9) **43** (1964), 177–185.

The integrability condition for $p = A(x, y, z, u)$, $q = B(x, y, z, u)$ yields a linear partial differential equation for the auxiliary unknown $u(x, y, z)$. Under the usual type of restrictions, Cauchy conditions for $z(x, y)$ extend to Cauchy conditions for u, and the method of characteristics applies to give a solution that may be viewed in the form $[x(u, v), y, z, u]$ with parameters u and v. In (x, y, z)-space those points on this surface with indeterminate normal are projections of points on the surface in (x, y, z, u)-space with a tangent line parallel to the u-axis. In general, such points form the curves that are mentioned in the title of the paper. A first-order partial differential equation that depends on a parameter, and in a limiting case has a degenerate solution, is investigated by the above method. *A. Newlander, Jr.* (Denver, Colo.)

Kušnirčuk, I. F. [Kušnirčuk, Ĭ. F.] 6148

On the Cauchy problem for equations of higher order with multiple characteristics. (Russian)

Approximate methods of solving differential equations, pp. 54–59. *Izdat. Akad. Nauk Ukrain. SSR, Kiev*, 1963.

Consider the equation in two independent variables

$$\prod_1^m \left(\frac{\partial}{\partial x} + (c(x) + \gamma_s)\frac{\partial}{\partial w}\right)^{k_s} f(w, x) + Df(w, x) = h(w, x),$$

where $\sum k_s = n$ and D is a differential operator of order less than n. This is a differential equation of order n with m distinct characteristics. This paper shows that if and only if D is of order less than m, the above equation can be reduced to Bianchi's equation

$$(-1)^n \partial^n F/\partial t_1 \cdots \partial t_n + \cdots = H(t),$$

and hence [reference is made to M. K. Fage, Mat. Sb. (N.S.) **45** (**87**) (1958), 281–322; MR **21** #1456] the Cauchy problem can be solved. *G. Hufford* (Boulder, Colo.)

Wu, Zhueng-hai [Wu, Chung-hai] 6149

Theorems on differential inequalities for nonlinear Bianchi equations.

Acta Math. Sinica **13** (1963), 584–606 (*Chinese*); *translated as Chinese Math.* **4** (1964), 637–660.

The author derives comparison theorems for solutions of the Cauchy and characteristic problems for the non-linear Bianchi equation

$$u_{xyz} = F(x, y, z, u, u_x, u_y, u_z, u_{yz}, u_{zx}, u_{xy}).$$

For example, with $F \in C^3$, suppose that $v_{xyz} = \bar{F}(x, \cdots, u_{xy})$ and that u and v have identical C^2 Cauchy data on a non-characteristic initial manifold. If $\bar{F} \le F$, then $u \le v$ in a non-vanishing region whose size depends on inequalities on the partial derivatives of F alone with respect to $u, u_x, \cdots, u_{xy}$. Assuming stronger inequalities on these partial derivatives, the derivatives of u and v are compared. Similar results are given for the characteristic problem in which u is assigned on the boundary of an octant. The main ingredient of the proof is a study of properties of the Riemann function for the linearized equation. *L. Sarason* (Stanford, Calif.)

Zerner, Martin 6150

Solutions singulières d'équations aux dérivées partielles.

Bull. Soc. Math. France **91** (1963), 203–226.

Soit $a(x, \partial/\partial x)$ un opérateur linéaire à coefficients analytiques. Il s'agit de préciser les propriétés géométriques des points singuliers d'une fonction ou plutôt d'une distribution u vérifiant $a(x, \partial/\partial x)u(x) = 0$.

Désignons par Sg(u) l'ensemble des points au voisinage desquels u n'est pas une fonction indéfiniment différentiable. L'auteur définit d'abord la notion de la caractéristique au sens de Lie simple. Dans le cas où la partie principale g de a est réel, le théorème suivant est démontré. Soit V une caractéristique au sens de Lie simple et analytique. Tout point $x_0 \in V$ possède un voisinage W sur lequel une distribution u est définie qui vérifie $au=0$ et $\mathrm{Sg}(u)=V \cap W$. Dans le cas où g n'est pas réel, ce résultat est encore vrai, si l'on suppose une condition entre la partie réelle et la partie imaginaire de g. La démonstration est basée essentiellement sur la méthode d'Hadamard. Finalement, dans le cas où a est matriciel et constant, un résultat précis est démontré.

Zitarosa, Antonio 6151

Sul problema di Nicoletti per le equazioni a derivate parziali.

Matematiche (Catania) **17** (1962), 85–120.

L'equazione che sta a base del problema di Nicoletti è costituita da una funzione incognita, derivata n volte rispetto ad x ed m rispetto ad y, eguagliata ad una funzione nota delle variabili indipendenti e di tutte le derivate di ordine più basso; sul contorno del dominio rettangolare sono assegnate le condizioni sulla funzione e sulle derivate non miste.

L'autore dimostra teoremi di esistenza, unicità e dipendenza della soluzione delle condizioni al contorno. Lo studio si basa su un teorema di J. Schauder relativo alla esistenza di elementi uniti in una trasformazione funzionale.

Il metodo qui proposto consente di ottenere nuovi teoremi rispetto a quelli stabiliti da F. Guglielmino mediante un metodo fondato sullo stesso citato teorema.

A. Pozzi (Naples)

Markovs'kiĭ, A. I. 6152

Well-posed boundary-value problems in L^2 for differential equations with constant coefficients in a half-space. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1964**, 861–865.

The problem is to find conditions on the Cauchy data for the solvability in L^2 of the equation $P(D)u = \sum_{k=0}^{m} P_{m-k}(i\partial/\partial x)(\partial^k/\partial t^k)u = 0$ for $t \geq 0$, $x \in \mathbf{R}^n$, where the P_j are polynomials with constant coefficients of degree $\leq p$, with $P_0 \equiv 1$ [cf. G. Dikopolov and G. Šilov, Izv. Akad. Nauk SSSR Ser. Mat. **24** (1960), 369–380; MR **22** #11219; Sibirsk. Mat. Ž. **1** (1960), 45–61; MR **23** #A3381]. Various conditions for solvability and correctness are given.

R. Carroll (Urbana, Ill.)

Cannon, J. R. 6153

Error estimates for some unstable continuation problems.

J. Soc. Indust. Appl. Math. **12** (1964), 270–284.

Supposto che $p(x)$, $\rho(x)$ $(0 \leq x \leq 1)$ siano funzioni positive e due volte differenziabili e che $q(x)$ $(0 \leq x \leq 1)$ sia una funzione continua e non negativa, si considera il problema

$$Lu = (p(x)u_x)_x + \rho(x)u_{yy} - q(x)u = 0$$

$$(0 < x < 1,\ y > 0),$$

$$u(0,y) = f_1(y), \qquad u(1,y) = f_2(y) \qquad (y \geq 0),$$

$$u(x,Y) = F(x) \qquad (0 \leq x \leq 1),$$

$$F(0) = f_1(Y), \qquad F(1) = f_2(Y) \qquad (0 < Y < \infty),$$

dove $F(x)$ è continua per $0 \leq x \leq 1$, e due volte differenziabile per $0 < x < 1$, mentre $f_1(y)$ e $f_2(y)$ sono continue e limitate per $0 \leq y < \infty$. Nel presente lavoro, supposta l'esistenza di una soluzione $u(x,y)$ del problema in questione, la quale è continua e limitata per $0 \leq x \leq 1$, $0 \leq y < \infty$, viene dato un metodo per approssimare la soluzione $u(x,y)$, quando le funzioni $F(x)$, $f_1(y)$, $f_2(y)$ sono note a meno di un dato errore, e inoltre si suppone che esista una costante $M_1 > 0$, tale che $|u(x,0)| \leq M_1$ $(0 \leq x \leq 1)$.

S. Cinquini (Pavia)

Geymonat, G. 6154

Su un problema relativo alle soluzioni delle equazioni lineari ellittiche.

Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 87–110.

Consider the boundary-value problem

$$Au = 0 \text{ in } \Omega, \qquad \gamma_j u = \phi_j \text{ on } \Gamma, \qquad j = 0, \cdots, m-1,$$

where Ω is a bounded domain in R^n with sufficiently regular boundary Γ, A is a linear, properly elliptic, partial differential operator of order $2m$ with sufficiently regular coefficients, and $\gamma_j = \partial^j/\partial\nu^j$ is the normal derivative of order j. Let S_j, $j=0, \cdots, m-1$, be the Neumann boundary operator associated with the γ_j. By this is meant that for $u, v \in C^{2m}(\bar\Omega)$

$$(Au, v) - (u, A^*v) = \sum_{j=0}^{m-1} \int_\Gamma \{S_j u \overline{\gamma_j v} - \gamma_j u \overline{T_j v}\}\, d\sigma$$

holds, where A^* is the formal adjoint of A. The operator $\phi = \{\phi_0, \cdots, \phi_{m-1}\} \to \mathcal{F}(\phi) = \{S_0 u, \cdots, S_{m-1} u\}$ is known to be continuous from

$$\prod_{j=0}^{m-1} W^{s-j-1/p,p}(\Gamma) \quad \text{to} \quad \prod_{j=0}^{m-1} W^{s-2m+j+1-1/p,p}(\Gamma)$$

for $1 < p < \infty$, $0 \leq s \leq m$, provided that $s - 1/p$ is not an integer, where $W^{t,p}(\Gamma)$ are the trace classes of Lions. The author now extends this, for $n=2$, to the case when $s-1/p$ is an integer. In this case the boundary values are not understood in the sense of completion by continuity of smooth functions, but rather as convergence in the mean on curves parallel to Γ. The method is based on the study of properties of an auxiliary function constructed by Agmon [Comm. Pure Appl. Math. **10** (1957), 179–239; MR **21** #5057] and Miranda [Ann. Mat. Pura Appl. (4) **46** (1958), 265–311; MR **23** #A1927].

Harnack's inequality for solutions of elliptic differential equations of second order. (Russian. English summary)

Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, no. 3, 3–14.

In this note an inequality of the form $\max u \leq c(\min u + r^{\gamma})$ (where the maximum and minimum are taken over a sphere $|x| < r$) is derived for non-negative weak solutions of elliptic equations

$$\sum_{i,j=1}^{n} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial u}{\partial x_j}\right) + \sum_i b_i(x)u_{x_i} + c(x)u + f(x) = 0.$$

The results are contained in the very general study of the reviewer [Acta Math. 111 (1964), 247–302; MR 30 #337] which appeared simultaneously with the present note.

Lithner, Lars 6157

A theorem of the Phragmén-Lindelöf type for second-order elliptic operators.

Ark. Mat. 5, 281–285 (1964).

On the region $|x| \geq r$ contained in E^n, let L be the uniformly elliptic operator given by

$$-\sum_{i,k} a_{ik}(x)\frac{\partial^2}{\partial x_i \partial x_k} + \sum_1^n b_k \frac{\partial}{\partial x_k} + a(x),$$

where a is positive and continuously differentiable, and a_{ik} and $b_k \to 0$ as $|x| \to \infty$. The author shows that if u is in $L_2(|x| \geq r)$ and satisfies $Lu = 0$, then for every positive ε, $ue^{(1-\varepsilon)\varphi}$ and $|\nabla u|e^{(1-\varepsilon)\varphi}$ belong to $L_2(|x| \geq r)$; here $\varphi(x) = \inf_\Gamma |\int_\Gamma (a(x)\sum_{i,k} a_{ik}'(x)\,dx_i\,dx_k)^{1/2}|$, Γ is a curve connecting 0 and x, and a_{ik}' is the matrix inverse to a_{ik}.

An example is given to show that ε may not be taken as zero. The proof, which is straightforward, is carried out in detail only for the case $L = -\Delta + a(x)$.

On the reduction of boundary value problems for elliptical systems of equations of higher order to problems for systems of first order. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukrain. RSR 1960, 1162–1166.

Author's summary: "The author describes a method of reducing boundary-value problems for elliptical systems of differential equations of a higher order to the corresponding problems of systems of the first order, which is a modification of an earlier method of the author [Dokl. Akad. Nauk SSSR 114 (1957), 462–464; MR 20 #5960]. On the basis of this reduction the normal solvability of the boundary-value problem for a higher-order system is proved and a formula is derived for its index."

Dubinskii, Ju. A. 6160

Some integral inequalities and the solvability of degenerate quasi-linear elliptic systems of differential equations. (Russian)

Mat. Sb. (*N.S.*) 64 (106) (1964), 458–480.

The author presents a series of inequalities relating integrals of powers of an arbitrary function and its derivatives over a domain D and its boundary Γ in n dimensions, and which are obtained by particular integrations by parts, using the Sobolev embedding theorems and the Hölder-Young inequality. These inequalities are applied to prove the existence of a generalized solution of the first boundary-value problem for a quasilinear system of divergence form and of order $2m$, under a weakened ellipticity hypothesis which permits the associated energy integral to degenerate in certain ways. The underlying idea is to base the definition of generalized solution on the square summability of $D(D^{m-1}u)^{\alpha}$, $\alpha > 0$, rather than on that of $D^m u$, as has been done in the past. The type of degeneration permitted is illustrated by the single equation

$$\sum_1^n \frac{\partial}{\partial x_i}\left(|u|^{\alpha_i}\frac{\partial u}{\partial x_i}\right) = f(x), \qquad \alpha_i \geq 0,$$

which is accessible to the method.

The general inequalities presented have an independent interest and can be expected to find application also in other problems of analysis.

Herzog, John O. 6161

Phragmén-Lindelöf theorems for second order quasi-linear elliptic partial differential equations.

Proc. Amer. Math. Soc. 15 (1964), 721–728.

The author derives Phragmén-Lindelöf type theorems for quasi-linear elliptic partial differential equations of the form

$$L[u] \equiv \sum a_{ij}(x,p)\partial^2 u/\partial x_i \partial x_j - f(x,u,p),$$

where the principal assumptions are: (1) The form a_{ij} is positive definite at every point x, p; (2) For suitable β, γ, $|f(x,u,p)| \leq \beta|p|^{2\gamma}$ and $\partial f/\partial u \geq 0$. One result is that if D is an unbounded domain contained in a half-space of n-dimensional Euclidean space, then, if $L[u] \geq 0$ and if the upper limit of $u(x)$ is nonpositive as x approaches any point on the boundary of D, and if $\limsup_{r\to\infty}(M(r)/r^{\eta}) \leq 0$ for some $\eta > 0$ (where $M(r) = \text{lub } u(x)$, for $|x| = r$, $x \in D$), one may conclude that $u(x) \leq 0$ throughout D. Further, one can take $\eta = 1$, if $f \equiv 0$ and $n = 2$, or if D is contained in the cone $x_n \geq r \sin\delta$, for some δ, $0 < \delta < \pi/2$.

This paper is an extension of previous papers and methods of proof by D. Gilbarg [J. Rational Mech. Anal. 1 (1952), 411–417; MR 14, 279], E. Hopf [ibid. 1 (1952), 419–424; MR 14, 279], J. B. Serrin [ibid. 3 (1954), 395–413; MR 16, 42], and A. Friedman [Pacific J. Math. 7 (1957), 1563–1575; MR 20 #7142]. Reference should have also been made to the extension of the Hopf maximum principle given by R. Redheffer [Monatsh. Math. 62 (1958), 76–83; MR 19, 1041; ibid. 66 (1962), 32–42; MR 26 #446].

R. Barrar (Santa Monica, Calif.)

Simoda, Seturo 6162

Traité sur la théorie des équations elliptiques et semi-linéaires. IV.

Mem. Osaka Univ. Lib. Arts Ed. Ser. B No. 12 (1963), 1–9.

Part III appeared in same Mem. No. 11 (1962), 1–22 [MR 28 #1372]. This portion of the author's series of papers contains an existence theorem for the Dirichlet

problem for a semi-linear elliptic differential equation of the form

$$(*)\qquad \sum_{i,j=1}^{n} a_{ij}(x)\partial_{ij}{}^2 u(x) = f(x, u, \nabla u).$$

There are several conditions on f, one of the principal ones being that there exist constants β and γ such that $|f(x, u, p)| \le \beta|p|^2+\gamma$ when (x, u, p) are suitably restricted. The author obtains an a priori bound for the gradient of a solution of (*). He then states an existence theorem. The proof is not given but is said to be essentially that contained in the work of M. Nagumo [Osaka Math. J. 6 (1954), 207–229; MR 16, 1116].

Intorno alle classi funzionali di Gevrey. (English summary)

Ann. Mat. Pura Appl. (4) **63** (1963), 151–173.

The classes of infinitely differentiable functions defined by inequalities of the form $|g^{(n)}(x)| \le LI^n\Gamma(mn+1)$, introduced by Gevrey in 1918, have again become fashionable, in part due to Hörmander's result [*Linear partial differential operators*, Chapter IV, § 4, Academic Press, New York, 1963; MR 28 #4221], according to which the solution of a hypo-elliptic partial differential equation belongs to such a class. For further recent applications see, e.g., Friberg's thesis [Medd. Lunds Univ. Mat. Sem. 17 (1963); MR 28 #349] and a lecture by Leray [Leray and Ohya Séminaire sur les Équations aux Dérivées Partielles, Fasc. I. Exposé 2°, pp. 20–71, Collège de France, Paris, 1964].

Let E be a subset of N-dimensional euclidean space R_N and $m=(m_1, \cdots, m_N)$ an N-tuple of real numbers. The author considers the class G^m of infinitely differentiable functions g on E such that for every compact subset K of E there exists $L>0$ which verifies

$$(*)\qquad |D^n g(x)| \le L^{|n|+1}n_1{}^{m_1n_1}\cdots n_N{}^{m_Nn_N}$$

for all N-tuples $n=(n_1, \cdots, n_N)$ of positive integers and all $x\in K$, where

$$|n| = n_1+\cdots+n_N \quad\text{and}\quad D^n = \partial^{|n|}/\partial x_1{}^{n_1}\cdots\partial x_N{}^{n_N}.$$

If the m_i are ≥ 0, then (*) is equivalent to $|D^n g(x)| \le LI^{|n|}\Gamma(\langle m, n\rangle+1)$ for all n and all $x\in K$, where $\langle m, n\rangle = m_1n_1+\cdots+m_Nn_N$. Given $L>0$, $l>0$, $h\ge 0$ and $m=(m_1, \cdots, m_N)$ with $m_i\ge 0$, the author also introduces the class $G(m, l; L, h)$ of functions which verify $|D^n g(x)| \le Ll^{|n|}\Gamma(\langle m, n\rangle+h+1)$ for all n and all $x\in E$. He proves that $g\in G(m, l; L, h)$ implies $D^n g\in G(m, l; Ll^{|n|}, h+\langle m, n\rangle)$ and $f\in G(m, l; L, h)$, $g\in G(m, l; M, k)$ with $m_i\ge 1$ imply $fg\in G(m, l; LM/(h+k+1), h+k+1)$. For the case $N=1$, $m\ge 0$, the author characterizes the functions of G^m by the behavior of their Fourier transforms and their Fourier coefficients.

Next he shows that if $p>q$, $1\le m<p/q$, $H(x, y, t)$ is a function defined in $a\le x\le b$, $|y|\le r$, $t(t-y)\le 0$, such that with respect to the variable x the function $(y-t)^{1-q}H$ belongs to G^m for every y and t, and $g(x, y)$ ($a\le x\le b$, $|y|\le r$) belongs to G^m with respect to x for every y, then the integro-differential equation $u(x, y)=g(x, y)+\int_0^y (H(x, y, t)\partial^p u(x, t)/\partial x^p)\,dt$ has a unique solution $u(x, y)$ which belongs to G^m with respect to x. The solution is given by a Neumann series. There is a substitute result for the case $m=p/q$.

Finally, the author proves that the partial differential operator $e^{i\lambda\pi/2}\,\partial^m/\partial x_1{}^m+\partial^n/\partial x_2{}^n$ is hypo-elliptic in the following two cases and only in these: (1) $m+\lambda-n$ is not an even integer, (2) m, n and $\frac{1}{2}(m+\lambda-n)$ are even integers.

Talenti, Giorgio 6164

Un problema di Cauchy.

Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 165–186.

We keep the notation of the preceding review [#6163]. Let now E be the closure of an open subset of R_N, $N\ge 1$ an integer, $p=(p_1, \cdots, p_N)$, $p_i\ge 0$, $f(x, t)$ a continuous function for $x\in E$, $|t|\le T$, and $u_r(x)$ functions of class C^{n-r} ($r=0, \cdots, n-1$) for $x\in E$. Set $P_{n-i}(D)=\sum_{\langle p,h\rangle\ge n-i} a_{hi}D^h$ ($i=0, \cdots, n-1$), where the coefficients a_{hi} are constant. The author proves that the Cauchy problem

$$\frac{\partial^n u}{\partial t^n} = \sum_{i=0}^{n-1} P_{n-i}(D)\frac{\partial^i u}{\partial t^i}+f, \qquad \frac{\partial^r}{\partial t^r}u(x, 0) = u_r(x)$$

$$(r = 0, \cdots, n-1)$$

has one and only one solution $u(x, t)$ for which $u(x, t)-\sum_{r=0}^{n-1}(u_r(x)t^r/r!)$ belongs to G^p with respect to x, provided (1) the function

$$g(x, t) = f(x, t)+\sum_{i=0}^{n-1}\sum_{r=i}^{n-1} P_{n-i}(D)u_r(x)\frac{t^{r-i}}{(r-i)!}$$

belongs to G^p with respect to x, (2) if

$$l > \limsup_{|n|\to\infty}\left(\max_{\substack{x\in E\\ |t|\le T}}\frac{|D^n g(x, t)|}{\Gamma(\langle m, p\rangle+1)}\right)^{1/|n|},$$

then $\sum_{i=1}^{n}\sum_{\langle p,h\rangle\ge i}|a_{h,n-i}|l^{|h|}T^i<1$. An analogous result holds for variable coefficients a_{hi}. The method consists in transforming the Cauchy problem into the integro-differential equation

$$(1)\quad v(x, t) = g(x, t)+\sum_{i=1}^{n} P_i(D)\int_0^t \frac{(t-\tau)^{i-1}}{(i-1)!}\,v(x, \tau)\,d\tau$$

with the help of the substitution $v=\partial^n u/\partial t^n$.

Talenti, Giorgio 6165

Studio di una equazione integrodifferenziale non lineare.

Matematiche (Catania) **18** (1963), 129–138.

Let $G^{p,r}$ ($p\ge 0$, $r>0$) be the Banach space of all functions $u(x, t)$ defined in $R=\{(x, t)|\ 0<x<1,\ |t|<1\}$ such that $\partial^i u/\partial x^i$ is continuous and $(1-|t|)^{pi+1}(\partial^i u/\partial x^i)$ is bounded in R for $i=0, 1, \cdots$, and for which the norm

$$\|u\| = \sup_i \frac{r^{-i}}{\Gamma(pi+1)}\sup_{(x,t)\in R}(1-|t|)^{pi+1}\left|\frac{\partial^i u}{\partial x^i}(x, t)\right|$$

is finite. The author shows that the equation

$$u(x, t) = g(x, t)+\left[a+\frac{b}{4}\int_0^1 dx\int_{-1}^{1}(1-t^2)u(x, t)\,dt\right]$$

$$\times\frac{\partial}{\partial t}\int_0^t \frac{(t-\tau)^s}{\Gamma(s+1)}\frac{\partial^m u}{\partial x^m}(x, \tau)\,d\tau,$$

which, for $b=0$, $s=n$, becomes a particular case of (1) of the preceding review [#6164], has a solution $u(x,t)$ belonging to $G^{s/m,r}$, provided $|a|^{1/m}r<1$, $g\in G^{s/m,r}$ and $4|b|\cdot\|g\|r^m<(1-|a|r^m)^2$. The proof is based on the Banach-Caccioppoli contraction principle and on the observation that $(\partial/\partial t)\int_0^t((t-\tau)^p/\Gamma(p+1))(\partial/\partial x)\,d\tau$ is a continuous operator from $G^{p,r}$ into itself with norm $\leq r$.

J. Horváth (Vanves)

Tsutsumi, Akira 6166

On the uniqueness of the Cauchy problem for semi-elliptic partial differential equations. I, II.

Proc. Japan Acad. **39** (1963), 781–786; *ibid.* **39** (1963), 787–790.

The author studies a subclass of semi-elliptic differential operators, that is to say, operators of the form

$$P(x,D)=P_0(x,D)+Q(x,D),$$

$$P_0(x,D)=\sum_{|p:m|=1}a_p(x)D^p,$$

$$Q(x,D)=\sum_{j=1}^{n}\sum_{|p:m|<1-1/m_j}a_p(x)D^p,$$

where $D=((1/i)\partial/\partial x_1,\cdots,(1/i)\partial/\partial x_n)$, $m=(m_1,\cdots,m_n)$, m_j are positive integers, $|p:m|=(p_1/m_1)+\cdots+(p_n/m_n)$. The semi-ellipticity of $P(x,D)$ is expressed by the fact that the polynomial in $\xi=(\xi_1,\cdots,\xi_n)$, $P_0(x,\xi)$, has no zeros $\xi\in R^n$ which are different from zero. Under some further assumptions, two weighted L^2 estimates are proved, and the uniqueness of the Cauchy problem with data on a non-characteristic surface is derived. The methods are adapted from those of L. Hörmander [Math. Scand. 7 (1959), 177–190; MR **22** #12306].

F. Treves (Lafayette, Ind.)

Tsutsumi, Akira 6167

On the uniqueness of the Cauchy problem for semi-elliptic partial differential equations. III.

Proc. Japan Acad. **40** (1964), 259–261.

This is an improvement of the two papers above [see #6166] to the effect that one of the conditions imposed upon the differential operator $P(x,D)$, used to prove the main theorem in those papers, is superfluous. This main theorem is shown to be valid for semi-elliptic operators of multi-order $(m_1,\cdots,m_n)$ with $m_1\geq m_j$ $(2\leq j\leq n)$, such that, for any non-zero real vector $\xi'=(\xi_2,\cdots,\xi_n)$, all the (complex) roots ζ_1 of $P(x^0,\zeta_1,\xi')$ are simple.

An example of slow decay of the solution of the initial-boundary value problem for the wave equation in unbounded regions.

Bull. Amer. Math. Soc. **70** (1964), 633–636.

The solution of the equation $\Delta u-u_{tt}=0$ is considered in a domain $\mathcal{D}$ containing ∞ and bounded by $\mathcal{B}$, which consists of two planes intersecting at an angle α. When $\alpha=\pi/k$, $k=1,2,\cdots$, the solution of the initial-value problem satisfying $u=0$ or $\partial u/\partial n=0$ on $\mathcal{B}$ can be constructed by the reflection principle, and if the initial data have compact support, the solution is identically zero after a finite time. The author shows that if $\alpha\neq\pi/k$, the solution can be expressed as an integral over the initial data and decays pointwise for $\alpha=2\pi/(2k+1)$ like t^{-2k-3}. This demonstrates that one cannot expect exponentially decaying solutions in the exterior of star-shaped bodies if these bodies extend to infinity (proved for finite bodies by Lax, Morawetz and Phillips [same Bull. **68** (1962), 593–595; MR **26** #457]), and that the rate of decay is very sensitive to shape.

Leis, Rolf 6169

Zur Eindeutigkeit der Randwertaufgaben der Helmholtzschen Schwingungsgleichung.

Math. Z. **85** (1964), 141–153.

The purpose of this paper is to provide material for the extension of existence and uniqueness theorems for the Dirichlet and Neumann problems for the Helmholtz equation. The extension is from smooth boundaries to boundaries having a finite number of discontinuities in direction. The material is applicable to both interior and exterior problems. Specifically, the author derives the orders of magnitude of several integrals evaluated in the neighborhood of an angle where the boundary curve bends. These integrals are important in the existence and uniqueness theorems.

E. Pinney (Berkeley, Calif.)

Werner, Peter 6170

Über die Randwertprobleme der Helmholtzschen Schwingungsgleichung.

Math. Z. **85** (1964), 226–240.

In this paper the author establishes that the solution of the exterior Dirichlet problem for the Helmholtz equation can be approximated by a suitable interior problem. The precise statement of the theorem is as follows. Let F be a twice continuously differentiable closed surface separating E_3 into an interior domain G_i and an exterior domain G_a. On F suppose $g(x)$ is a given continuous function. Let K_r be a sphere, with center the origin and radius r, such that F is contained in K_r for $r>r_0$. Let G_r be the domain exterior to F and interior to K_r. Now if $U_r(x)$, where $r>r_0$, is a function with the properties (a) U_r is twice continuously differentiable in G_r and satisfies $(\Delta+k^2)U_r=0$ with k real; (b) U_r is continuous in G_r+F and on F satisfies $U_r=g$; (c) U_r is continuously differentiable in G_r+K_r and on K_r satisfies the boundary condition $(\partial/\partial r-ik)U_r=0$; then U_r exists and is unique. Further, if $k\neq0$, for $x\in G_a$, $U_r(x)\to U(x)$ as $r\to\infty$, where $U(x)$ is the solution of $(\Delta+k^2)U=0$ in G_a, $U(x)=g$ for x on F and $U(x)$ satisfies the Sommerfeld radiation condition. The convergence is proven to be uniform in any compact subdomain of G_a.

Extensions of the theorem are discussed. For instance, (b) can be replaced by the mixed boundary condition $\partial U_r/\partial n+hU_r=g$, where g and h are given continuous functions. The proof can be extended to Maxwell's equations with sinusoidal time dependence, provided Sommerfeld's radiation condition is replaced by the electromagnetic radiation condition.

Ash, M. E. 6172

The basic estimate of the $\bar\partial$-Neumann problem in the non-Kählerian case.

Amer. J. Math. **86** (1964), 247–254.

Consider a finite domain $\Omega \Subset \mathbf{R}^n$. Let E_1, E_2, E_3 be unitary vector spaces and $\mathfrak{E}_j$ the E_j-valued C^∞ functions on $\bar\Omega$. For $\varphi, \psi \in \mathfrak{E}_j$, set $(\varphi, \psi) = \int_\Omega \langle\varphi, \psi\rangle$. Suppose that $D : \mathfrak{E}_1 \to \mathfrak{E}_2$, $D^1 : \mathfrak{E}_2 \to \mathfrak{E}_3$ are constant-coefficient differential operators. Then the adjoints D^*, D^{1*} of D, D^1 are defined, as is the Laplace operator $L = D^{1*}D^1 + DD^*$, on a subspace $\mathscr{L} \subset \mathfrak{E}_2$. Assume that $\mathfrak{E}_1 \xrightarrow{D} \mathfrak{E}_2 \xrightarrow{D^1} \mathfrak{E}_3$ is such that L is elliptic. Then integration by parts leads directly to the following formula: For $\varphi \in \mathscr{L}$,

$$(1)\quad (L\varphi, \varphi) = \|D^1\varphi\|^2 + \|D^*\varphi\|^2 = \int_\Omega Q\langle\nabla\varphi, \nabla\varphi\rangle + \int_{\partial\Omega} L\langle\varphi, \varphi\rangle,$$

where $Q\langle\nabla\varphi, \nabla\varphi\rangle$ is a quadratic form in φ and its first derivatives and $L\langle\varphi, \varphi\rangle$ is an ordinary quadratic form. If Ω is convex, then $L\langle\varphi, \varphi\rangle \geqq c|\varphi|^2$ $(c > 0)$. Furthermore, if φ has compact support, $\int_\Omega Q\langle\nabla\varphi, \nabla\varphi\rangle \geqq \text{const} \int_\Omega |\nabla\varphi|^2$. Furthermore, in certain favourable cases, $Q\langle\nabla\varphi, \nabla\varphi\rangle \geqq 0$ and (1) becomes

$$(2)\qquad (L\varphi, \varphi) \geqq \text{const} \int_\Omega L\langle\varphi, \varphi\rangle.$$

This happens, for instance, if $n = 2m$, $\mathbf{R}^n = \mathbf{C}^m$, $E_j = \Lambda^{q+j}\mathbf{C}^m$, $\mathfrak{E}_j$ are $C^\infty(0, q+j)$ forms on $\bar\Omega$, and $D = \bar\partial = D^1$. In this case, $Q\langle\nabla\varphi, \nabla\varphi\rangle = |\bar\nabla\varphi|^2 = \sum_{i=1}^m |\partial\varphi/\partial\bar z_i|^2$ and L is essentially the E. E. Levi form of Ω. Another good case is when $E_j = \Lambda^{q+j}\mathbf{R}^n$, $\mathfrak{E}_j$ are $C^\infty(0, q+j)$ forms on $\bar\Omega$, and $D = d = D^1$ is the exterior derivative. Then $Q\langle\nabla\varphi, \nabla\varphi\rangle = |\nabla\varphi|^2$ and L is the second fundamental form of the hypersurface $\partial\Omega \subset \mathbf{R}^n$.

Now let X be a manifold, $\Omega \Subset X$ a finite open domain, E_1, E_2, E_3 vector bundles over Ω, $\mathfrak{E}_j$ the C^∞ sections of E_j over $\bar\Omega$, and $D : \mathfrak{E}_1 \to \mathfrak{E}_2$, $D^1 : \mathfrak{E}_2 \to \mathfrak{E}_3$ differential operators. By putting metrics in the E_j and on X, we may define $(\varphi, \psi) = \int_\Omega \langle\varphi, \psi\rangle$ $(\varphi, \psi \in \mathfrak{E}_j)$. Then D^*, D^{1*}, and $L = D^*D + D^1D^{1*}$ are defined. Given any point $x_0 \in X$, the bundle operators induce an osculating constant-coefficient situation on the fibres $(E_j)_{x_0}$ and tangent space at x_0, and the essential content of this paper is to show how, in some special favorable cases, the constant-coefficient inequality (2) may be reduced to the analogous statement on X. The necessary computations, which are of a differential-geometric nature, are efficiently executed by using the "moving frame" calculus of E. Cartan.

In closing, there are a few historical comments which seem relevant. The genesis of the inequality (2), for the $\bar\partial$-operator and L the E. E. Levi form, is found in C. B. Morrey, Jr. [Ann. of Math. (2) **68** (1958), 159–201; MR **20** #5504]. The general inequality was obtained and extensive applications to several complex variables were given in J. Kohn's treatment of the so-called $\bar\partial$-Neumann problem [ibid. (2) **78** (1963), 112–148; MR **27** #2999]. (The basic formalism in this question and the ensuing boundary-value problem were set up by D. C. Spencer.) On the other hand, there is a formula in Riemannian geometry [cf. S. Bochner and K. Yano, *Curvature and Betti numbers*, Chapter III, Princeton Univ. Press, Princeton, N.J., 1953; MR **15**, 989] which, even for general manifolds, gives (1) in the case that E_j is the bundle of $q+j$ forms and $D = d = D^1$; then there must be added to the right-hand side of (1) a term $R(\varphi, \varphi) = \int_\Omega R\langle\varphi, \varphi\rangle$, where R is the Riemannian curvature on X. Here $L = \mathrm{II}$ is the second fundamental form of $\partial\Omega$ in X. This has been used by C. C. Hsiung [Math. Z. **82** (1963), 67–81; MR **27** #2943] to obtain vanishing theorems for ordinary cohomology on Ω.

Burnat, M. 6173

Über die Spektraldarstellung des Operators $-\Delta u + q(x_1, x_2, x_3)u$ mit dreifach periodischen $q(x_1, x_2, x_3)$ im Raume der fastperiodischen Funktionen.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 255–259.

In a previous paper [same Bull. **10** (1962), 247–253; MR **26** #6476] the author considered an eigenvalue problem motivated by a one-dimensional crystal and employs the Hilbert space B^2 of Besicovitch almost periodic functions to establish some theorems on the spectrum of the operator $-u'' + q(x)u$ (with periodic $q(x)$). In the present paper similar theorems are briefly stated for the three-dimensional case, and the reader is referred to another paper [Studia Math. **25** (1964), 33–64] for further details.

G. H. Meisters (Boulder, Colo.)

Burnat, M. 6174

Die wesentliche Selbstadjungiertheit des Operators $Lu = -\Delta u + q(x_1, x_2, x_3)u$ mit unendlich vielen Singularitäten in $q(x_1, x_2, x_3)$.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 261–264.

The author remarks that Nils Nilsson [Kungl. Fysiogr. Sällsk. i Lund Förh. **29** (1959), no. 1, 1–19; MR **21** #3652] and others have shown that the operator $-\Delta u + q(x)u$ is essentially self-adjoint if $q(x)$ possesses only a finite number of singular points. Then, motivated by the quantum theory of crystals, the author considers the case that $q(x)$ has infinitely many singular points and proves a similar result.

G. H. Meisters (Boulder, Colo.)

Frasca, Michele 6175

Un problema variazionale per operatori ellittici.

Matematiche (Catania) **18** (1963), 1–11.

Suppose the bounded domain A is of class C^2 and φ is of

class C^2 on the boundary ∂A. Let $\mathscr{L}_{\alpha\gamma\delta}$ be a class of elliptic operators L of the form

$$Lu \equiv au_{xx}+2bu_{xy}+cu_{yy}+a_1u_x+b_1u_y+c_1u,$$

where the coefficients are bounded and measurable on A and satisfy

$$a\lambda^2+2b\lambda\mu+c\mu^2 \geq \alpha(\lambda^2+\mu^2),$$
$$a+c = 1+\alpha,\ 0<\alpha\leq 1,$$
$$a_1^2+b_1^2 \leq \delta^2, \quad -\gamma\leq c_1\leq 0, \quad \gamma,\delta\geq 0.$$

If f is given, there is a unique solution $u\in C_\mu^1(A)\cap H_2^2(A)$ of $Lu=f$ for which $u=\varphi$ on ∂A. The author shows that if $(x_0,y_0)\in G$, there are unique functions u_1 and u_2 such that $u_1(x_0,y_0)\leq u(x_0,y_0)\leq u_2(x_0,y_0)$ for all solutions u for all $L\in\mathscr{L}_{\alpha\gamma\delta}$. The same functions work for every (x_0,y_0) in A and satisfy certain non-linear equations.

Giesecke, Burghart 6176

Zum Dirichletschen Prinzip für selbstadjungierte elliptische Differentialoperatoren.

Math. Z. **86** (1964), 54–62.

Green's theorem and the consequent Dirichlet and Thompson principles are proved in a slightly non-standard manner. The proof holds for an arbitrary, not necessarily bounded, domain.

A significant result is contained in the proof of Theorem 4. Namely, for an arbitrary bounded domain G, any function in $C^1(G)\cap C^0(\bar{G})\cap H^1(G)$ which vanishes on ∂G is in $H_0^1(G)$. In fact, the same result is proved for an unbounded domain with respect to the norm

$$\left\{\int_G [a^{ij}u_{x_i}u_{x_j}+qu^2]\,dx\right\}^{1/2}$$

when $q\in L^2(G)$ and the function approaches zero at infinity.

Kreiss, Heinz-Otto 6177

Über sachgemässe Cauchyprobleme.

Math. Scand. **13** (1963), 109–128.

Given a linear partial differential equation written in matrix form, $\partial u/\partial t=P(x,t;\partial/\partial x)u$, we say that the Cauchy problem is well-posed if there exists a constant C such that, for all t_1,t_2, $0\leq t_1\leq t_2\leq T$, we have $\|u(x,t_2)\|_{L^2}\leq C\|u(x,t_1)\|_{L^2}$. The author considers this problem along the ideas of Petrowsky and Leray. Some precise results are obtained in the case where the coefficients are constant. Next, parabolic and hyperbolic equations are discussed in detail from this point of view. Finally, the author shows that the treatment of hyperbolic equations can be extended to the case where the matrix $\sum_{k=1}^n A_k(x,t)\omega_k$ has a simple structure and has only real eigenvalues. This last question is closely connected with the reviewer's paper [Mem. College Sci. Univ. Kyoto Ser. A Math. **32** (1959), 181–212; MR **23** #A420].

S. Mizohata (Kyoto)

Kumano-go, Hitoshi 6178

On the uniqueness for the solution of the Cauchy problem.

Osaka Math. J. **15** (1963), 151–172.

The uniqueness theorem of the solutions of the Cauchy problem for the differential equation

$$Lu = \sum_{j+|\alpha|\leq m} a_{j,\alpha}(t,x)\frac{\partial^{j+|\alpha|}}{\partial t^j\partial x^{|\alpha|}}u(t,x) = f(t,x)$$

has been investigated by many authors. However, these investigations do not cover some interesting cases. For example, the reviewer proved the following result [Mem. College Sci. Univ. Kyoto Ser. A Math. **31** (1958), 219–239; MR **21** #5081]: The parabolic equation

$$Lu = \left(\sum_{i,j=1}^n a_{ij}(t,x)\frac{\partial^2}{\partial x_i\partial x_j} + \sum b_i(t,x)\frac{\partial}{\partial x_i}+c(t,x)-\frac{\partial}{\partial t}\right)u(t,x) = f(t,x),$$

with data prescribed on a piece of time-like hypersurface, has the unique continuation property.

In this paper, the author proposes a systematic treatment of such equations. Let

$$Lu = L_0u + \sum_{j+m|\alpha:m|\leq m-1} b_{j,\alpha}(t,x)\frac{\partial^{j+|\alpha|}}{\partial t^j\partial x^{|\alpha|}}u(t,x) = f(t,x),$$

where $|\alpha:m| = \alpha_1/m_1+\alpha_2/m_2+\cdots+\alpha_\nu/m_\nu$, $m\geq m_i$, and

$$L_0u = \sum_{j+m|\alpha:m|=m} a_{j,\alpha}(t,x)\frac{\partial^{j+|\alpha|}}{\partial t^j\partial x^{|\alpha|}}u(t,x),$$

which is called the principal part of L. The author establishes a uniqueness theorem for this type of equation after extending the notion of singular integral operators. The results obtained here can be applied to a large class of operators.

Matsumura, Hideyuki 6179

On an algebraic lemma of L. Hörmander. (Japanese)

Sûgaku **13** (1961/62), 159–160.

The author, after showing the invalidity of Lemma 3.2 of L. Hörmander's thesis [Acta Math. **94** (1955), 161–248; MR **17**, 853] by a counter-example: $R=k[x^2,x^3]$, gives another proof of the following generalized form of Lemma 3.3: If $f_1(X),\cdots,f_r(X)\in k[X_1,\cdots,X_n]$, and if $k(f_1,\cdots,f_r)$ is of degree of transcendency 1 over k, then there exists a polynomial W such that $k(f_1,\cdots,f_r)=k(W)$, $k[f_1,\cdots,f_r]\subset k[W]\subset k[X_1,\cdots,X_n]$. Using this lemma, the author shows that all defects concerning Lemmas 3.2 and 3.3 in Hörmander's paper are covered.

Odeh, Farouk; Keller, Joseph B. 6180

Partial differential equations with periodic coefficients and Bloch waves in crystals.

J. Mathematical Phys. **5** (1964), 1499–1504.

Let V be a real continuous function on R_3, and (a_{ij}) a symmetric differentiable matrix such that the operator $-\sum_{i,j=1}^3(\partial/\partial x_i)(a_{ij}\,\partial/\partial x_j)+V$ is uniformly elliptic. Let H be its unique self-adjoint extension on $L_2(R_3)$. Require it to be invariant under the discrete group of translations of R_3 generated by three orthogonal vectors. Ω^* will be a closed unit cell in the reciprocal lattice defined by these three vectors.

The authors justify rigorously the following facts from a generalization of Floquet's theory, which has been

widely used in the theory of solids. There exists a complete set of eigenfunctions ("Bloch waves") of the form $\exp(2\pi ik\cdot x)\phi_n(x,k)$, where k varies over Ω^* and ϕ_n is a smooth function of x invariant under the discrete group. The functions $\exp(2\pi ik\cdot x)\phi_n(x,k_0)$ ("Kohn-Luttinger waves") are also complete for any fixed k_0 in Ω^*. The spectrum of H is a countable union of closed intervals. Then the analytic dependence on k of the eigenfunctions and corresponding eigenvalues is discussed.

Schechter, Martin 6181

Systems of partial differential equations in a half-space. *Comm. Pure Appl. Math.* **17** (1964), 423–434.

Boundary problems for systems of partial differential equations with constant coefficients in a half-space $x_n>0$ of R^n are studied. An inequality of the type

$$\left\|\sum_j R_j(D)u_j\right\| \leq C\left(\sum_i\left\|\sum_j P_{ij}(D)u_j\right\|+\sum_j\|u_j\|\right),$$

where $\|\ \|$ is the L_2 norm, for functions $u\in C^\infty$ in $x_n\geq 0$ and with compact support also satisfying the boundary condition

$$\sum Q_{ij}u_j=0,\qquad x_n=0,$$

is established under proper assumptions on P_{ij} and Q_{ij}, the R_j being essentially "weaker" (in Hörmander's sense) than the P_{ij}. This extends earlier work in the case of one single equation [the reviewer, Math. Scand. **9** (1961), 337–351; MR **26** #4039; the author, Ann. Scuola Norm. Sup. Pisa (3) **18** (1964), 255–282]; the method of proof is similar.

Problème de Cauchy hyperbolique et espaces fonctionnels de S. L. Sobolev. *Les Équations aux Dérivées Partielles (Paris, 1962)*, pp. 25–31. *Éditions du Centre National de la Recherche Scientifique, Paris*, 1963.

Comme on sait, pour la résolution des equations hyperboliques quasi-linéaires, l'estimation a priori joue un rôle essentiel. Il s'agit ici de résoudre, dans une bande et sous les hypothèses les plus faibles, le problème de Cauchy régulièrement hyperbolique de façon à obtenir les résultats locaux les plus forts possibles.

Le principal résultat obtenu ici est qu'il suffit de pouvoir majorer a priori les dérivées d'ordre $m+\frac{1}{2}(l+3)$ (J. Leray avait obtenu $m+l+3$) de la solution d'un problème non linéaire d'ordre m dans un domaine de dimension l pour avoir un théorème global d'existence.

Pour montrer ce résultat, l'auteur utilise des propriétés assez fines des espaces fonctionnels de Sobolev.

Chaillou, J. 6184

Opérateurs hyperboliques à partie principale tendant vers zéro. Comportement de la solution élémentaire. *Les Équations aux Dérivées Partielles (Paris, 1962)*, pp. 19–24. *Éditions du Centre National de la Recherche Scientifique, Paris*, 1963.

Soit $a_\varepsilon(\partial/\partial x,\partial/\partial y)=\varepsilon g+a_0$, où $a_0=g'+a_1$ est un opérateur à deux variables à coefficients réels et constants. Supposons que (1) g est hyperbolique et homogène d'ordre m, (2) g' est quelconque et homogène d'ordre $m-1$, (3) a_1 est d'ordre $m-2$. Supposons de plus que $g(t,1)$ et $g'(t,1)$ n'ont pas de zéro commun. Désignons par $E_\varepsilon(x,y)$ la solution élémentaire de a_ε. L'auteur donne une condition nécessaire et suffisante pour que $E_\varepsilon(x,y)$ tende vers une limite finie, lorsque $\varepsilon\to 0$, en dehors des demi-droites caractéristiques de g et de g'. La démonstration est assez délicate. D'abord, l'auteur montre une expression explicite de $E_\varepsilon(x,y)$ au moyen des résidus et puis utilise un résultat de M. Morse.

Gloistehn, H. H. 6185

Monotoniesätze und Fehlerabschätzungen für Anfangswertaufgaben mit hyperbolischer Differentialgleichung. *Arch. Rational Mech. Anal.* **14** (1963), 384–404.

This paper deals with a quasilinear hyperbolic operator

$$Tu\equiv -h^2(x,y)u_{xx}+u_{yy}+F(x,y,u,u_x,u_y),$$

and a related first-order system defined by

$$(1)\qquad \begin{aligned} L_{11}u &\equiv hu_x+u_y+\alpha_1u=v_1,\\ L_{12}u &\equiv -hu_x+u_y+\alpha_2u=v_2,\end{aligned}$$

and

$$(2)\qquad \begin{aligned} hv_{1x}+v_{1y}+\beta_1v_1 &= Tu+G_1(x,y,u,v_1,v_2),\\ hv_{2x}+v_{2y}+\beta_2v_2 &= Tu+G_2(x,y,u,v_1,v_2).\end{aligned}$$

Here α_j and β_j $(j=1,2)$ are arbitrary functions, and G_1 and G_2 are defined by (2) and (1). The principal result of the paper is the following monotony theorem. Let B be a triangle in the (x,y)-plane, bounded by two characteristic arcs for T and a non-characteristic arc Γ. Assume that $G_j(x,y,u,v_1,v_2)$ is monotone nondecreasing in u, v_1 and v_2 $(j=1,2)$ and $\alpha_j(x,y)\geq 0$ on Γ $(j=1,2)$. Then $Tu<Tw$ in B, $\pm hu_x+u_y<\pm hw_x+w_y$ on Γ implies $u<w$, $L_{11}u<L_{11}w$ and $L_{12}u<L_{12}w$ in $B+\Gamma$. (The precise differentiability assumptions on u, v, h, $\alpha_j(x,y)$, $\beta_j(x,y)$ and $F(x,y,u,u_x,u_y)$ which are given by the author have been omitted for brevity.)

The monotony theorem is used to derive a number of error estimates for approximate solutions of initial-value problems for the operator T. The results generalize theorems of S. Agmon, L. Nirenberg and M. H. Protter [Comm. Pure Appl. Math. **6** (1953), 455–470; MR **15**, 432], M. H. Protter [Trans. Amer. Math. Soc. **71** (1951), 416–429; MR **14**, 281; ibid. **87** (1958), 119–129; MR **20**

#4079], H. F. Weinberger [Ann. of Math. (2) 64 (1956), 505–513; MR 19, 1058] and W. Walter [Arch. Rational Mech. Anal. 7 (1961), 249–272; MR 23 #A2640].

C. H. Wilcox (Madison, Wis.)

Kolodner, Ignace I. 6186

On the Carleman's model for the Boltzmann equation and its generalizations.

Ann. Mat. Pura Appl. (4) **63** (1963), 11–32.

T. Carleman has shown that the system

$$(1)\qquad \begin{aligned} u_{+,t}+u_{+,x} &= u_-^2-u_+^2,\\ u_{-,t}-u_{-,x} &= u_+^2-u_-^2 \end{aligned}$$

has many features in common with the integro-differential equation of Boltzmann [T. Carleman, *Problèmes mathématiques dans la théorie cinétique des gaz*, Almqvist and Wiksells, Uppsala, 1957; MR 20 #4935]. The pair (u_+, u_-) may be interpreted as the velocity distribution function of a fictive one-dimensional gas whose molecules travel with only two velocities, $+1$ and -1, and interact according to the collisional terms on the right-hand side of (1). With this interpretation, $\rho=u_++u_-$ is the number density and $c=(u_+-u_-)/\rho$ is the average mass velocity. They satisfy the moment equations

$$(2)\qquad \begin{aligned} &\rho_t+(\rho c)_x = 0, &&\text{the equation of continuity, and}\\ &(\rho c)_t+\rho_x = -2\rho^2 c, &&\text{the equation of momentum.} \end{aligned}$$

The system (2) is equivalent to (1). Moreover, the study of (2) can be reduced to the study of a single second-order equation by observing that if ϕ solves

$$(3)\qquad \phi_{tt}-\phi_{xx} = -2\phi_x\phi_t,$$

then $(\rho, c)=(\phi_x, -\phi_t/\phi_x)$ solves (2). The quantity

$$H(t) = \int_{-\infty}^{\infty} (u_+\log u_+ + u_-\log u_-)\,dx$$

plays the role of the total entropy of the gas, and the analogue of the H-theorem, $H'(t)\leq 0$, holds for solutions of (1) which satisfy suitable regularity assumptions.

This paper deals with the Cauchy problem for the system (1). The local existence and uniqueness theory can be established by well-known techniques [see Chapter V of R. Courant and D. Hilbert, *Methods of mathematical physics*, Vol. II, Interscience, New York, 1962; MR 25 #4216]. In this paper the author proves a global existence theorem for (1) in the strip $R\times(0,a)$ and the half-plane $R\times(0,\infty)$. The results are derived by exploiting the fact that the solution of a certain Riccati equation depends isotonically (with respect to a suitable partial order) on the forcing term and the initial data. Generalizations of the theory to systems having several dependent variables are discussed in a final section.

C. H. Wilcox (Madison, Wis.)

Lewis, Robert M. 6187

Asymptotic methods for the solution of dispersive hyperbolic equations.

Asymptotic Solutions of Differential Equations and Their Applications (Proc. Sympos., Math. Res. Center, U.S. Army, Univ. Wisconsin, Madison, Wis., 1964), pp. 53–107. *Wiley, New York*, 1964.

A heuristic method is described for asymptotic solution as $\lambda\to\infty$ of a symmetric hyperbolic system

$$\sum_0^n A^\nu \partial u/\partial x_\nu+\lambda Bu = f(t,x,\lambda), \qquad u(0,x) = u_0(x,\lambda),$$

together with boundary conditions, where B is anti-symmetric. The method is applicable to the problem of dispersion of electromagnetic waves in dielectrics, among others. It is akin to J. B. Keller's ray method in diffraction theory [B. R. Levy and J. B. Keller, Comm. Pure Appl. Math. 12 (1959), 159–209; MR 21 #1130]. It may be roughly described as follows. In the case of problems that can be solved exactly, the asymptotic expansion of the solution reveals that it consists of a sum of terms, each of which is an asymptotic power series in λ^{-1} multiplied by a phase function, the coefficients in the series being amplitude functions. The basic assumptions of the author's theory is that for more complex problems the solutions have the same asymptotic form. The phase functions are then found by the method of characteristics, and the amplitude functions are found by solving the transport equations that must be satisfied if the asymptotic solution is to formally satisfy the system of partial differential equations. In some cases, the initial conditions necessary to determine the proper rays (characteristics), phase functions, and amplitude functions are obtained from the solution of a canonical problem (a solvable one with the same local features as the given problem). That this may be done is the author's second main hypothesis.

The method is illustrated by applying it to a number of initial-boundary-value problems for the homogeneous and inhomogeneous wave equation

$$u_{tt}-c^2(x)\Delta u+\lambda^2 b^2(x)u = \lambda^2 f(x,t,\lambda),$$

involving oscillatory initial data and oscillatory sources.

N. D. Kazarinoff (Ann Arbor, Mich.)

Walk, Manfred 6188

Über das Cauchysche Anfangswertproblem schwach nichtlinearer hyperbolischer Differentialgleichungen.

Math. Nachr. **27** (1963), 9–28.

This paper deals with the following initial-value problem:

$$(1)\qquad \sum_{i,k=1}^{2} a_{ik}\left(\frac{\partial u}{\partial x_1}, \frac{\partial u}{\partial x_2}, u\right)\frac{\partial^2 u}{\partial x_i\partial x_k}-\frac{\partial^2 u}{\partial t^2} = F(x_1,x_2,t), \qquad (x_1,x_2,t)\in\Omega,$$

$$(2)\qquad u(x_1,x_2,0) = \phi(x_1,x_2), \qquad \frac{\partial u(x_1,x_2,0)}{\partial t} = \psi(x_1,x_2), \qquad (x_1,x_2)\in\Omega_0.$$

Here Ω is the frustrum of a cone in (x_1,x_2,t)-space with its axis parallel to the t-axis and of height T. Ω_0 is the base of Ω (the intersection of Ω with the plane $t=0$). The existence of a solution for sufficiently small T was proved by J. Schauder [Fund. Math. 24 (1935), 213–246] with the help of his fixed-point theorem. The same result was proved by S. L. Sobolev [*Some applications of functional analysis in mathematical physics* (Russian), Izdat. Leningrad. Gos. Univ., Leningrad, 1950; MR 14, 565], using modern functional analysis.

In this paper the author proves the existence of a solution for arbitrary values of T, under the assumption

that the nonlinearity is not too large. More precisely, he assumes that

$$\mathfrak{A}_{ik}\left(\frac{\partial u}{\partial x_1}, \frac{\partial u}{\partial x_2}, u\right) = \delta_{ik} + \lambda A_{ik}\left(\frac{\partial u}{\partial x_1}, \frac{\partial u}{\partial x_2}, u\right),$$

where $|A_{ik}(\xi_1, \xi_2, \xi_3)| \leq R$ for all i, k, ξ_1, ξ_2 and ξ_3, and λ is not too large. Estimates for the allowable values of λ are given.

The proof makes use of the linearized problem

$$(3) \quad \sum_{i,k=1}^{2} \mathfrak{A}_{ik}\left(\frac{\partial z}{\partial x_1}, \frac{\partial z}{\partial x_2}, z\right) \frac{\partial^2 v}{\partial x_i \partial x_k} - \frac{\partial^2 v}{\partial t^2} = F(x_1, x_2, t), \qquad (x_1, x_2, t) \in \Omega,$$

with initial conditions (2). If z is continuously differentiable in the closure of Ω, this defines a unique solution v, and the original problem (1), (2) is equivalent to finding a fixed point for the mapping $z \to v = \Phi(z)$. The author shows that if λ is not too large, Φ has a fixed point in a subset of the Sobolev space $W_2^{(r+1)}(\Omega)$ with $r \geq 4$. The proof is based on the following estimate for the solution of the linear problem (2), (3):

$$\|v\|_{W_2^{(\nu)}(\Omega)} \leq P_1(\|F\|_{W_2^{(\nu-1)}} + \|\phi\|_{W_2^{(\nu)}} + \|\psi\|_{W_2^{(\nu-1)}}) \times \exp\{\lambda P_2(1 + \|z\|_{W_2^{(r+1)}}) \exp N\|z\|_{W_2^{(r+1)}}\}$$

for $\nu = 0, 1, 2, \cdots, r+1$, where P_1, P_2 and N depend on Ω and the A_{ik} only.

As an example, the results are applied to the equation for the torsional oscillations of an elastic, circularly cylindrical shaft:

$$\frac{\partial}{\partial x}\left[f(T^2)\frac{\partial u}{\partial x}\right] + \frac{\partial}{\partial y}\left[f(T^2)\frac{\partial u}{\partial y}\right] - \frac{\partial^2 u}{\partial t^2} = F(x, y, t),$$

$$T^2 = \left(\frac{\partial u}{\partial x}\right)^2 + \left(\frac{\partial u}{\partial y}\right)^2.$$

C. H. Wilcox (Madison, Wis.)

Agmon, Shmuel 6189

Problèmes mixtes pour les équations hyperboliques d'ordre supérieur.

Les Équations aux Dérivées Partielles (Paris, 1962), pp. 13–18. *Éditions du Centre National de la Recherche Scientifique, Paris,* 1963.

Soit $A(D_x, D_t)$ un opérateur différentiel hyperbolique d'ordre m à coefficients constants. L'auteur considère les problèmes aux limites de la forme:

$$A(D_x, D_t)u(x, t) = f(x, t) \qquad (0 \leq t \leq T, x_n \geq 0),$$

$$D_t^j u|_{t=0} = 0 \qquad (x_n \geq 0, j = 0, 1, \cdots, m-1),$$

$$B_j(D_x, D_t)u|_{x_n=0} = 0 \qquad (0 \leq t \leq T, j = 1, 2, \cdots, l).$$

$\{B_j(D_x, D_t)\}$ est un système d'opérateurs différentiels à coefficients constants d'ordre $m_j < m$, sans termes d'ordre inférieur.

L'auteur énonce que, dans ce cas, on peut caractériser les problèmes bien posés, d'en tirer les majorations L^2 typiques et d'obtenir les résultats d'existence. La démonstration n'est pas donnée ici. Cette recherche est sans doute une contribution importante aux problèmes mixtes pour les équations hyperboliques. *S. Mizohata* (Kyoto)

A mixed problem for the general third- and fourth-order hyperbolic equations on the plane. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1149–1151.

Author's summary: "Using the method of L. Gårding, the author proves the existence and the uniqueness of the solution for the mixed problem for general hyperbolic equations of the third and fourth order on a plane."

Blagoveščenskiĭ, Ju. N. 6191

The Cauchy problem for degenerate quasi-linear parabolic equations. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 378–382.

The author considers the Cauchy problem for the quasi-linear parabolic equation

$$(*) \qquad \frac{\partial v}{\partial t} = \frac{b^2(t, x, v)}{2}\frac{\partial^2 v}{\partial x^2} + a(t, x, v)\frac{\partial v}{\partial x}$$

with given initial conditions $v(0, x) = \phi(x)$. This problem was studied by O. A. Ladyženskaja and N. N. Ural'ceva [Izv. Akad. Nauk SSSR Ser. Mat. **26** (1962), 5–52] under the assumption $b(t, x, v) \geq a_0 > 0$ for all (t, x, v). In the paper being reviewed $b(t, x, v)$ is allowed to be 0 and it is assumed only that the $a(t, x, v)$, $\phi(x)$, and $b(t, x, v)$ satisfy various smoothness conditions. The method of solution is to solve successively the equations

$$(**) \quad \frac{\partial v_n}{\partial t} = \frac{b^2(t, x, v_{n-1}(t, x))}{2}\frac{\partial^2 v_n}{\partial x^2} + a(t, x, v_{n-1}(t, x))\frac{\partial v_n}{\partial x}$$

with $v_n(0, x) = \phi(x)$, $v_0(t, x) = \phi(x)$. When v_{n-1} is known, the equation (**) is linear and is solved by constructing a diffusion process $\{x_n(t)\}$ satisfying a corresponding stochastic integral equation. Then $v_n(t) = \mathbf{M}[\phi(x_n(t))]$ solves (**) and $v_n(t)$ converges as $n \to \infty$ to a solution $v(t)$ of (*).

Cannon, J. R. 6192

A priori estimate for continuation of the solution of the heat equation in the space variable.

Ann. Mat. Pura Appl. (4) **65** (1964), 377–387.

Suppose that $u(x, t)$ is a continuous function in the region

$$D = \{(x, t): x_1(t) \leq x \leq x_3(t), 0 \leq t \leq T\}$$

such that

$$(a) \qquad u_t = u_{xx}, \quad x_1(t) < x < x_3(t), \quad 0 < t \leq T,$$

$$(b) \qquad u(x, 0) = 0, \quad x_1(0) \leq x \leq x_3(0),$$

$$(c) \qquad u(x_2(t), t) = f(t), \quad 0 \leq t \leq T, \quad f(0) = 0,$$

$$(d) \qquad u(x_3(t), t) = g(t), \quad 0 \leq t \leq T, \quad g(0) = 0,$$

$$x_1(t) < x_2(t) < x_3(t),$$

$$(e) \qquad |u(x_1(t), t)| \leq M_0,$$

where $x_1(t)$, $x_3(t)$ are Lipschitz continuous and $x_2(t)$, $f(t)$, and $g(t)$ are continuous. If $v(x, t)$ is a bounded, continuous function on D satisfying (a), (b), and (e), then the author obtains an a priori estimate for $|u(x, t) - v(x, t)|$, $x_1(t) < x < x_2(t)$, in terms of $\varepsilon(t)$, where $\varepsilon(t)$ is

$$\max\left\{\sup_{0 \leq \tau \leq t} |v(x_2(\tau), \tau) - f(\tau)|, \sup_{0 \leq \tau \leq t} |v(x_3(\tau), \tau) - g(\tau)|\right\}.$$

A method is discussed for calculating $v(x,t)$ in such a way that $s(t)$ is as small as possible.

Abstract analyticity in time and unique continuation property of solutions of a parabolic equation.

J. Fac. Sci. Univ. Tokyo Sect. I **9**, 1–11 (1961).

The analytic semi-group $e^{tA} = U(t)$ has been characterized by K. Yosida [Proc. Japan Acad. **35** (1959), 109–113; MR **21** #4298]. The author considers the case where A depends on t:

$$\frac{d}{dt}u(t) = A(t)u(t),$$

where the space is a fixed Banach space. Following the method of Tanabe [cf. Osaka Math. J. **11** (1959), 121–145; MR **22** #4964], the author obtains the following result. Assume $\mathcal{D}(A(t))$ is independent of t and moreover $B(t) = A(t)A_0^{-1}$ is analytic in t; if, for $0 \leq t \leq T$, a certain uniformity concerning the analytic semi-group property is satisfied, then $U(t,s)$ is analytic in (t,s) for $t > s$. Some applications are given.

Lu, Wei-mian; Wang, Guang-fa; Chen, Pu-quan; Wang, Shao-shang; Sun, Jing-sen 6194

On the Cauchy problem for a parabolic Monge-Ampère equation.

Acta Math. Sinica **12** (1962), 273–277 (*Chinese*); *translated as Chinese Math.* **3** (1963), 302–306.

The authors consider the Monge-Ampère parabolic equation

$$L(u) = xr + 2ys - y^2 + rt - s^2 = 0$$

with initial conditions $u(x, 0) = u_0(x)$, $u_y(x, 0) = q_0(x)$. They transform it to a hyperbolic Monge-Ampère equation by the simple device of considering the equation $L(u) + a^2 = 0$, where a is a small constant. They then prove that as $a \to 0$ the solution of the hyperbolic equation approaches that of the parabolic equation. The same procedure is used in a more complicated case by K. Wang, T. Chen, and T. Mei [same Acta **14** (1964), 78–92; MR **29** #377].

The Tricomi problem for a multiply connected domain. (Russian)

Boundary-value problems in the theory of functions of a complex variable, pp. 73–79. *Izdat. Kazan. Univ., Kazan,* 1962.

The Tricomi problem for the equation in polar coordinates of mixed type

$$(1) \qquad r^2u_{rr} + ru_r + (\operatorname{sgn}(1-r))u_{\varphi\varphi} = 0$$

is considered in a multiply connected domain D of the (r, φ)-plane, divided by the unit circle $r = 1$ into two simply connected parts D_1 and D_2. D_1, the portion interior to the circle, is bounded by $m+1$ piecewise smooth curves $\sigma_1, \cdots, \sigma_m$, each of which consists of two circular arcs orthogonal to the unit circle, and intersects it at $2(m+1)$ points $t_0, t_0', \cdots, t_m, t_m'$. D_2 is outside the unit circle, between the circle and the pairs of characteristics $\gamma_0, \gamma_0', \cdots, \gamma_m, \gamma_m'$ of (1) passing through the points $t_0, t_0', \cdots, t_m, t_m'$, respectively.

A unique solution $u(r, \varphi)$ in D to the equation (1) is found which vanishes on the arcs $\sigma_1, \cdots, \sigma_m$ and assumes given values on the characteristics $\gamma_1, \cdots, \gamma_m$. This is an extension of work of A. V. Bicadze [*On the problem of equations of mixed type* (Russian), Trudy Mat. Inst. Steklov, Vol 41, Izdat. Akad. Nauk SSSR, Moscow, 1953; MR **16**, 43], V. G. Karmanov [Dokl. Akad. Nauk SSSR **95** (1954), 439–442; MR **16**, 369], and others [see L. Bers, *Mathematical aspects of subsonic and transonic gas dynamics*, Wiley, New York, 1958; MR **20** #2960].

The authors' work is based on a reduction of the problem in the ellipticity domain D_1 to a Riemann boundary problem for an automorphic function on the unit circle, for which a solution in terms of the Cauchy principal value is found. In D_2 the solution of Bicadze is used.

On the Tricomi problem with derivatives in the boundary conditions. (Russian)

Kazan. Gos. Univ. Učen. Zap. **122** (1962), *kn.* 3, 30–53.

In this article the author gives a method of solving a boundary problem for the equations of Lavrentieff and Bicadze.

The article consists of five sections. The first three contain the lemmas and theorems used in the proof of problem (T_k). This problem is posed in the fourth section and the solution is given in the fifth.

The problem (T_k) is too long to write here, so it will be only sketched. The considered domain D is a connected domain bounded by a simple arc Γ lying in the half-plane $y \geq 0$, having the endpoints $A(0,0)$ and $B(1,0)$, as well as by the characteristic of (1) AC: $x + y = 0$, $y \leq 0$, and BC: $x - y = 1$, $y \geq 0$. Denote by L the arc Γ and the interval AB. L has continuous curvature. The domain bounded by L and the domain bounded by the interval AB and the characteristics AC and BC will be denoted by D_1 and D_2, respectively.

Problem (T_4). Find a function $u(x, y)$ having the properties: $u(x, y)$ satisfies equation (1), the corresponding partial derivatives satisfy some prescribed conditions, and

$$\sum_{k=0}^{n} \sum_{j=0}^{k} a_{kj}(t) \frac{\partial^k u(t)}{\partial x^{k-j}\partial y^j} = b(t), \qquad t \in \Gamma,$$

where the functions $a_{kj}(t)$ and $b(t)$ have the Hölder property on Γ, and $\sum_{j=0}^{n} i^j a_{nj}(t) \neq 0$. Finally, $u(x, y)$, which is continuous in $\bar{D}_2$, satisfies a boundary condition on AC. *L. Pintér* (Szeged)

Nazarov, G. I. 6199

Bergman functions in the theory of flow of a compressible fluid. (Russian)

Tomsk. Gos. Univ. Učen. Zap. No. 49 (1964), 13 pp.

Bergman's integral operator generates the stream functions ψ of compressible fluids. If ψ is considered in the (s, θ)-plane, where s is a function of the speed and θ the angle which the velocity vector forms with the x-axis of the physical plane, then ψ satisfies a linear partial differential equation of mixed type. In the slightly modified form obtained by von Mises and Schiffer [see *Advances in applied mechanics*, pp. 249–285, Academic Press, New York, 1948; MR **10**, 642] and in the subsonic region this operator has the form $\psi(s, \theta) = A + B\theta + \operatorname{Im} \sum_{n=0}^{\infty} R_n(u, \bar{u}) f_n(s)$, $u = s + i$, $\bar{u} = s - i$. Here $f_n(s)$ are certain fixed functions. They depend only upon the equation which ψ satisfies, while $R_n(u, \bar{u}) = \phi_n(u) + F_n(\bar{u})$ are arbitrary harmonic functions which are connected by the relations $\phi_n(u) = \int \phi_{n-1}(u)\, du$, $F_n(\bar{u}) = \int F_{n-1}(\bar{u})\, d\bar{u}$, $n = 1, 2, \cdots$. The function $R_0(u, \bar{u})$ depends upon the profile around which the flow takes place. The author gives an explicit formula for the functions $f_n(s)$, given by (2.21) of the reviewed paper. Similar formulas are obtained for the stream functions ψ in the supersonic region.

The above results are of great interest, particularly in the numerical determination of flow patterns of compressible fluids. *B. Chalmers* (Stanford, Calif.)

Prouse, Giovanni 6200

Esempi tipici per l'equazione delle onde.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) **34** (1963), 143–150.

L'auteur étudie un problème mixte bien posé pour l'équation des ondes mise sous la forme $x''(t) = Ax(t) + f(t)$. Posons $f_\tau(t) = f(t + \tau)$. L'auteur construit f telle que la fonction $\tau \to f_\tau$ soit uniformément continue de $\mathbf{R}$ dans $L^2([-\frac{1}{2}, \frac{1}{2}] \times U)$, l'image de $\mathbf{R}$ par cette fonction soit relativement compacte, la fonction $\tau \to x_\tau'$ n'ait aucune de ces deux propriétés, mais l'intégrale d'énergie entre $\tau - \frac{1}{2}$ et $\tau + \frac{1}{2}$ reste bornée quand τ varie.

La méthode employée s'applique à plusieurs autres situations analogues. *M. Zerner* (Marseille)

Fujita, Hiroshi 6201

The unique existence of solutions for the initial-value problem of Navier-Stokes equations. (Japanese)

Sûgaku **14** (1962/63), 65–81.

The author discusses the Navier-Stokes initial-value problem:

$$(1) \quad \partial_t u = \Delta u - \nabla p + f - (u \cdot \nabla) u \qquad (x \in D,\ t > 0),$$

$$(2) \quad \operatorname{div} u = 0 \qquad (x \in D,\ t > 0),$$

$$(3) \quad u|_{\partial D} = 0 \qquad (t > 0),$$

$$(4) \quad u|_{t=0} = a \qquad (x \in D),$$

which can be written in operational form as

$$(5) \quad du/dt = -Au + Pf - P(u \cdot \nabla) u \qquad (t > 0),$$

$$(6) \quad \|u(t) - a\| \to 0 \qquad (t \downarrow 0).$$

The first part concerns the strong solution and has the same aim as his previous paper with T. Kato [Rend. Sem. Mat. Univ. Padova **32** (1962), 243–260; MR **26** #495]. But the method of treatment is different in that this time the author makes use of Odqvist's Green's tensor $G(x, y)$, $g(x)$, assuming the boundary ∂D to be of class C^3. Then by using the fact that the solution of the Stokes problem:

$$(7) \quad \Delta v - \nabla q = -f, \qquad \operatorname{div} v = 0, \qquad v|_{\partial D} = 0$$

can be represented as

$$(8) \quad v(x) = \int_D G(x, y) f(y)\, dy = \mathbf{G} f, \qquad q(x) = \int_D g(x, y) f(y)\, dy = \mathbf{g} f,$$

he shows that the following relations hold

$$(9) \quad \mathbf{G} P h = \mathbf{G} h \quad \text{for any } h \in \mathscr{H} \text{ (i.e., } L_2(D) \text{ space)},$$

$$(10) \quad A^{-1} = \mathbf{G} \quad \text{as the operator on } \mathscr{H}_\sigma \text{ such that } \mathscr{H} = \mathscr{H}_\sigma \oplus \mathscr{H}_\pi$$

and is able to obtain the following more precise results.

Theorem 1. Let $a \in D(A^\beta)$ for some $\frac{1}{2} < \beta < 1$ and $f \in C_s^\theta[0, T_1]$ (i.e., strong Hölder-continuity with exponent $0 < \theta < 1$), then to any γ satisfying $\frac{1}{2} < \gamma < 1$, $\beta - \gamma + \frac{1}{2} > 0$ there exists in some interval $[0, T]$ $(0 < T < T_1)$ a strong solution $u(t)$ of class $\mathscr{S}_t(\beta, \gamma)$, where $u \in \mathscr{S}(\beta, \gamma)$ means that the inequality

$$N(u, t, \beta, \gamma) \equiv \max(\|Au\|_{t,\gamma}, \|A^{1/2}u\|_{t,(\beta - \frac{1}{2})}) < \infty$$

holds for any $t \in [0, T]$. Moreover, such a solution is unique.

The last half concerns the regularity in the classical sense of the strong solution u, as was promised in the above cited paper. First, he shows that $u(t, x)$ is Hölder continuous in $\Omega_1 = I \times D$, $I = (0, T)$, and then by proving the integral representations

$$u(t, x) = \int_D G(x, y) w(t, y)\, dy, \qquad (t, x) \in \Omega = I \times D,$$

$$(11) \quad \partial_m u(t, x) = \int_D G_m(x, y) w(t, y)\, dy \qquad (m = 1, 2, 3),$$

$$p(t, x) = \int_D g(x, y) w(t, y)\, dy,$$

where $w = -du/dt - (u \cdot \nabla) u + f$, he deduces, under the additional assumptions:

$$(12) \quad f \in C_s^\theta(I; L_2(D)) \quad \text{with exponent } 1/2 < \theta < 1,$$

$$f \in C_s^\chi(I, L_q(D)) \quad \text{for some } 3 < q,\ 0 < \chi < 1,$$

that $\nabla u(t, x)$ and $p(t, x)$ are Hölder-continuous in Ω_1.

Finally, making use of Oseen's fundamental solution $E(t-s, x-y)$ of the Stokes initial-value problem: $\partial_t u = \Delta u - \nabla p$, div $u = 0$, which is defined by

$$(13)\quad E_{ij}(t-s, x-y) = \left(-\delta_{ij}\Delta_x + \frac{\partial^2}{\partial x_i \partial x_j}\right)\Phi(t-s, x-y),$$

where

$$\Phi(t, x) = \frac{1}{4\pi^{3/2}} \frac{1}{|x|\sqrt{t}} \int_0^{|x|} \exp\left(-\frac{\alpha^2}{4t}\right) d\alpha,$$

and using the above result in an ingenious way he proves the following (Theorem 2). Under the further assumption that $f(t, x)$ is Hölder-continuous in Ω, the strong solution in Theorem 1 is classical, i.e., (i) $u(t, x)$ is Hölder-continuous in Ω_1 and satisfies (3), (ii) $\nabla u(t, x)$, $\Delta u(t, x)$, $\partial_t u(t, x)$, $p(t, x)$ and $\nabla p(t, x)$ are Hölder-continuous in Ω and satisfy (1) and (2). *W. Sibagaki* (Fukuoka)

Golovkin, K. K.; Solonnikov, V. A. 6202

The first boundary-value problem for the non-stationary Navier-Stokes equations. (Russian)

Dokl. Akad. Nauk SSSR **140** (1961), 287–290.

The authors consider in $\Omega \times [0, T]$, where Ω is a bounded region of 3-dimensional space with the boundary surface S of Ljapunov type and $T > 0$, the boundary-value problem for the non-stationary Navier-Stokes equations. The velocity u is assumed to vanish on S. For a vector-function $v(x, t)$ defined for $x \in \bar{\Omega}$, $t > 0$, the following norm is introduced

$$|v(x, t)|_{\mathfrak{M}(\Omega, \beta)} = \max_{x \in \Omega} |v(x, t)| + \max_{x, x' \in \Omega} \frac{|v(x, t) - v(x', t)|}{|x - x'|^\beta}$$

for a certain $\beta > 0$. Theorem: if the exterior force f and the initial value a of u satisfy, for some $\beta > 0$, the conditions

$$\sup_{t > 0} |f(x, t)|_{\mathfrak{M}(\Omega, \beta)} < \infty,$$

$$\sup_{t, t' > 0} \max_{x \in \Omega} \frac{|f(x, t) - f(x, t')|}{|t - t'|^\beta} < \infty,$$

and $|a(x)|_{\mathfrak{M}(\Omega, \beta)} < \infty$, then for a certain $T > 0$ there exists in $\Omega \times [0, T]$ a classical solution of the problem considered. T depends upon $\sup_{t > 0} |f(x, t)|_{\mathfrak{M}(\Omega, \beta)}$ and $|a(x)|_{\mathfrak{M}(\Omega, \beta)}$ and is equal to ∞ if the latter are sufficiently small. The proof is based on some estimates, in terms of $|\ |_{\mathfrak{M}(\Omega, \beta)}$-norms, which are deduced by using the non-stationary hydrodynamical potentials. The latter are constructed by means of some special forms of fundamental solutions given by the authors. Moreover, the following theorem is formulated. The weak solution (in the sense of Kiselev and Ladyženskaja [Izv. Akad. Nauk SSSR Ser. Mat. **21** (1957), 655–680; MR **20** #6881]) u, p of the problem considered has the derivatives $u_{x_i x_j}$, u_t and p_x which belong to $L^{4/3}(\Omega \times [0, T])$. *A. FINITE DIFFERENCES AND FUNCTIONAL EQUATIONS

See also 6128, 6061.

Carlitz, L. 6203

A partial difference equation related to the Fibonacci numbers.

Fibonacci Quart. **2** (1964), 185–196.

The author considers the difference equation

$$u_{m,n} - u_{m-1,n} - u_{m,n-1} - u_{m-2,n} + 3u_{m-1,n-1} - u_{m,n-2} = 0,$$

where $m \geq 2$, $n \geq 2$ are integers. He shows that the general solution can be expressed in terms of the Fibonacci numbers. Formulas are not simple and the work involves elaborate and complicated but elementary transformations. *T. Fort* (Columbia, S.C.)

Huta, A. 6204

Eine Bemerkung zur Zerlegung der natürlichen Zahlen. (Slovak and Russian summaries)

Acta Fac. Natur. Univ. Comenian. **9**, 57–62 (1964).

Author's summary: "Bezeichnen wir mit $R_n(x)$ die Anzahl aller verschiedenen Zerlegungen einer natürlichen Zahl x in n Glieder (Summanden) unter folgenden Voraussetzungen: (1°) die Glieder sind natürliche Zahlen; (2°) die Zerlegungen mit zwar gleichen Gliedern, jedoch in anderer Reihenfolge, werden als gleiche angesehen. Werden also Glieder einer Zerlegung mit x_j, $j = 1, 2, \cdots, n$ bezeichnet, so kann man im weiteren voraussetzen, daß $x_i \leq x_j$ für $i < j$. Dann gilt die Relation

$$(1)\qquad R_n(x + n) - R_n(x) = R_{n-1}(x + n - 1)."$$

The author proves this relation. He then solves it recursively, that is, assuming $R_{n-1}(x + n - 1)$, he solves for $R_n(x)$ which now is a solution of a linear difference equation. He appends a table completed by equation (1) where x ranges from 1 to 15 and n from 1 to 4. *T. Fort* (Columbia, S.C.

Classification of singular points of difference equations in an n-dimensional space. (Russian)

Učen. Zap. Ural. Gos. Univ. **1959**, vyp. 23, 13–21.

Consider the system

$$(1)\qquad x_{n+1} = Ax_n + \varphi(x_n), \qquad n = 0, 1, 2, \cdots,$$

where A is a 2×2 matrix and $\varphi(x)$ is a 2-vector which is $o(|x|)$ as $|x| \to 0$. A singular or equilibrium point of (1) is a solution such that $x_n = x_0$ for $n = 1, 2, \cdots$. For the linear system (2) $x_{n+1} = Ax_n$, the solutions are expressible in terms of the characteristic roots of A and arbitrary periodic functions of period one. In the first paper under review, the author classifies the singular point 0 of (2) in terms of the characteristic roots of A. Some theorems are also given concerning the local preservation of the structure of the singular point when equation (2) is subjected to perturbations of the type φ as in (1).

The second paper considers similar questions for the case when A is an $n \times n$ matrix and the function φ also depends upon n. *J. K. Hale* (Providence, R.I.

Remarks on probable inference.

Ann. Univ. Sci. Budapest. Eötvös Sect. Math. **6** (1963), 3–11.

The author compares his work on the axiomatics of conditional probability [Magyar Tud. Akad. Mat. Kutató Int. Közl. **6** (1961), 111–121] with that of R. T. Cox [*The algebra of probable inference*, Johns Hopkins Press, Baltimore, Md., 1961; MR **24** #A563]. He points out a number of shortcomings in Cox's treatment of the subject. For example, he shows that the functional equations which Cox encountered and solved by assuming differentiability of the solution can be solved under considerably weaker hypotheses. From the point of view of functional equations, the interest of the paper lies in the equation $zf(f(y)/z) = yf(f(z)/y)$ for the one-place function f, which the author reduces to the pair of functional equations $F(xz, yz) = F(x, y)z$, $F(x, F(y, z)) = F(z, F(y, x))$ for the two-place function F given by $F(x, y) = xf(y/x)$. Using known results and techniques, this latter pair of equations is readily solved. *B. Schweizer* (Tucson, Ariz.)

Author's summary: "In der Arbeit untersucht man das Gleichungssystem (1) $f(\varepsilon z) = \lambda f(z)$, $f(1/z) = \mu f(z)$ wo λ und μ gegebene Konstanten sind und $\varepsilon = e^{2\pi i/n}$ (n – beliebige natürliche Zahl). In der Arbeit sind die notwendigen und hinreichenden Bedingungen für die Existenz einer meromorphen Lösung des Systems (1) erhalten und ist die allgemeine Lösung in der Klasse der meromorphen Funktionen angegeben. In Sonderfalle $\lambda = \mu = 1$ sind die Lösungen von (1) automorphe Funktionen mit Haupttransformationen $w = \varepsilon z$ und $w = 1/z$."

Laha, R. G.; Lukacs, E.; Rényi, A. 6209

A generalization of a theorem of E. Vincze. (Russian summary)

Magyar Tud. Akad. Mat. Kutató Int. Közl. **9** (1964), 237–239.

Vincze solved the functional equation $\phi(x) = \phi(ax)\phi(bx)$, $a, b > 0$; $a^2 + b^2 = 1$ [same Közl. 7 (1962), 357–361; MR **27** #2748]. The authors of this paper prove the following theorem in a straightforward manner. Let $\phi(x)$ be a complex-valued function of the real variable x and let $\{a_j\}$ be a sequence of non-negative real numbers such that $\sum a_j^2 = 1$ and $0 < a_1 < 1$. Suppose that there exist complex constants A and B such that

$$\lim_{x \to 0} \frac{\phi(x) - \phi(0) - Ax}{x^2} = B.$$

Assume further that $\phi(x)$ satisfies, for all real x, the functional equation $\phi(x) = \prod \phi(a_j x)$, where the infinite product converges. Then $A = 0$ and $\phi(x) = e^{Bx^2}$.

R. A. Rosenbaum (Middletown, Conn.)

Timan, A. F. 6210

A non-linear functional equation in the class of functions which are convex on a semi-axis. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **28** (1964), 515–526.

On considère sur $x \geq 0$ une fonction continue convexe ω avec $\omega(0) = 0$, $\sup_x \omega(x) = \infty$, et l'équation fonctionnelle $\sup_{x \geq 0} \{f(x) - \omega(x) \cdot y\} = \varphi(y)$, où $\varphi(y)$ est une fonction continue concave pour $y \geq 0$. On indique la relation entre l'existence d'une solution convexe et bornée d'une telle équation et la théorie d'approximation.

S. Mandelbrojt (Paris)

Vincze, E. 6211

Über eine Verallgemeinerung der Cauchyschen Funktionalgleichung.

Funkcial. Ekvac. **6** (1964), 55–62.

Let $(Q_0, *)$ be a commutative semigroup, Q the field of complex numbers, and f a mapping from Q_0 to Q. For any positive integer n, f is a solution of $f(z * w)^n = (f(z) + f(w))^n$ if and only if f is a solution of $f(z * w) = f(z) + f(w)$, i.e., in the set of all mappings from Q_0 to Q, the Cauchy equation and its nth power are equivalent. The main tool in the proof is the author's "Determinantenmethode" [Publ. Math. Debrecen **9** (1962), 149–163; MR **26** #502]. The special case $n = 2$, in a somewhat more general setting, was considered by the author [Arch. Math. **15** (1964), 132–135; MR **29** #390].

San Juan Llosá, R. 6212

The uniqueness problem in the theory of numerical divergent series and formal laws of calculus. I.

Collect. Math. **14** (1962), 235–255.

Let c be the space of convergent sequences $\{s_i\}$ with the norm $\|s\| = \sup_{0 \leq i < \infty} |s_i|$ and u the space of sequences $\{u_i\}$ such that $\sum_{i=0}^{\infty} u_i$ converges.

We have the following definition:

A sequence $\{\phi_n\} \in c$ of sequences $\{\phi_{n,i}\} \in c$ for $n = 0, 1, 2, \cdots$ and $i = 0, 1, 2, \cdots$ is complete in c when the only constant C and the only sequence $\{C_i\} \in u$ satisfying all the conditions,

$$C \lim_{i \to \infty} \phi_{n,i} + \sum_{i=0}^{\infty} \phi_{n,i} C_i = 0 \qquad (n = 0, 1, 2, \cdots)$$

are $C = 0$ and $C_i = 0$ for $i = 0, 1, 2, \cdots$.

Various theorems are proved about complete sequences in different spaces with parallel theorems for functions continuous on the positive real line.

G. M. Petersen (Swansea)

San Juan Llosá, R. 6213

The uniqueness problem in the theory of numerical divergent series and formal laws of calculus. II.

Collect. Math. **15** (1963), 23–70.

Let s_0 be the set of convergent sequences. The author discusses the problem: "To extend the isomorphism λ_0 by means of another isomorphism λ between a set $s_1 \supset s_0$

$(s_1 \neq s_0)$ and the same complex plane c with respect to certain formal laws, for instance the laws a, b, c, d, e, and f stated below in the weak form that will be used." Law f, for example, states: "The limit $\lambda \lim s_n$ is a linear continuous functional in the space s_1 with a topology."

A similar discussion is made concerning convergent series.

The fundamental theorem of van der Corput on uniform distribution and its generalizations.

Compositio Math. **16**, 29–34 (1964).

The contents of this paper were published earlier in a slightly different form [J. Reine Angew. Math. **210** (1962), 141–147; MR **25** #4273].

Thron, W. J. 6215

On the convergence of the even part of certain continued fractions.

Math. Z. **85** (1964), 268–273.

Linear fractional transformations and nested circular regions are used to prove the following result. If the complex numbers c_n satisfy

$$|c_{2n-1} \pm ia| \le p, \qquad |c_{2n} \pm i(1+a)| \ge p,$$
$$|c_{2n}^2| \ge p^2 - |1+a|^2 + \varepsilon,$$

where $\varepsilon > 0$, a is a complex number, and p satisfies $p > |a|$, $p \ge |1+a|$, then the sequence of even approximants of the continued fraction

$$1 + \frac{c_1^2}{1} + \frac{c_2^2}{1} + \cdots$$

converges to a value c which satisfies $|c - (1+a)| \le p$.

W. T. Scott (Tempe, Ariz.)

Bosanquet, L. S. 6216

On the order of magnitude of fractional differences.

Calcutta Math. Soc. Golden Jubilee Commemoration Vol. (1958/59), *Part I, pp.* 161–172. *Calcutta Math. Soc., Calcutta*, 1963.

For a sequence (u_n) we write

$$\Delta u_n = u_n - u_{n+1}, \quad \Delta^0 u_n = u_n \quad \text{and} \quad \Delta^s = \Delta\Delta^{s-1}$$
$$(s = 1, 2, 3, \cdots).$$

For all real ρ, the fractional difference is defined by

$$\Delta^\rho u_n = \sum_{\nu=n}^{\infty} A_{\nu-n}^{-\rho-1} u_\nu,$$

whenever the series on the right is convergent, A_n^ρ being defined for $\mu \ge 0$ by the identity

$$(1-x)^{-\rho-1} = \sum_{n=0}^{\infty} A_n^\rho x^n \qquad (|x| < 1).$$

When ρ is a non-negative integer, this definition reduces to the first one. For a sequence (v_n) the fractional difference with base at $-\infty$ is defined by

$$\nabla^\rho v_m = \sum_{n=-\infty}^{m} A_{m-n}^{-\rho-1} v_n,$$

whenever the series on the right is convergent. In particular, $\nabla^1 v_m = v_m - v_{m-1}$, and when ρ is a non-negative integer, we have $\nabla^\rho v_m = (-1)^\rho \Delta^\rho v_{m-\rho}$.

An analogue of a result of Hardy and Littlewood [Proc. London Math. Soc. (2) 11 (1913), 411–478] and variants of some results of Mordell [J. London Math. Soc. 3 (1928), 119–121] and Kloosterman [ibid. **15** (1940), 91–96; MR **2**, 89] is (D): If $W(n)$, $V(n)$ are positive and either both non-decreasing or both non-increasing and if $u_n = O(W)$, $\Delta^r u_n = O(V)$ for $n \ge 0$, where r is an integer greater than 1, then $\Delta^1 u_n = O(W^{1-(1/r)} V^{1/r})$. In the present paper the author extends (D) to fractional differences. The main result is given in Theorem 1: If $0 < \sigma < k$, $W(n)$, $V(n)$ are positive and non-increasing in the range $-\infty < n < \infty$, and if $u_n = O(W)$, $\Delta^k u_n = O(V)$ for $-\infty < n < \infty$, then $\Delta^\sigma u_n = O(W^{1-(\sigma/k)} V^{\sigma/k})$ for $-\infty < n < \infty$.

When W, V are non-decreasing, an equivalent result is proved in Theorem 2 for differences with base at $-\infty$. Some variants of Theorems 1 and 2 with o are given. Finally, by using an iteration formula for fractional differences due to Andersen [Mat. Tidsskr. B **1950**, 110–122; MR **12**, 404] and Kuttner [Proc. London Math. Soc. (3) 7 (1957), 453–466; MR **20** #1131], a result for differences of order σ ($\sigma_1 < \sigma < \sigma_2$ and σ_1 any real number, positive or negative) is obtained.

S. K. Basu (Calcutta)

Harris, W. A., Jr.; Turrittin, H. L. 6217

Reciprocals of inverse factorial series.

Funkcial. Ekvac. **6** (1964), 37–46.

This paper contains five interesting theorems on factorial series. Two of these theorems will be quoted. The reader can consult the paper for the other theorems.

Theorem: If $G(z)$ is analytic in a neighborhood of the origin and $F(z)$ can be represented by an inverse factorial series convergent in a right half-plane, then $\{G(F(z)) - G(0)\}$ also has a factorial series representation in some right half-plane.

Theorem: If $F(z)$ is a convergent inverse factorial series of the type

$$F(z) = \sum_{s=m}^{\infty} \frac{s!\,a_s}{z(z+1)\cdots(z+s)}, \qquad a_m \neq 0,\ \mathrm{Re}(z) > \lambda,$$

then $f(z) = F(z)/z^{m+1}$ is representable as a convergent inverse factorial series in some half-plane.

Iyer, A. V. V. 6218

The equivalence of two methods of absolute summability.

Proc. Japan Acad. **39** (1963), 429–431.

Let T be a summability method on sequences. If $T(s_n) = (t_n)$, then (s_n) is said to be absolutely T-summable or $|T|$-summable if $\sum |t_n - t_{n-1}|$ converges. Let $H(s_n) = (\sigma_n)$ and $H^*(s_n) = (\sigma_n^*)$, where

$$\sigma_n = \sum_{k=0}^{n} (n+1-k)^{-1} s_k \Big/ \sum_{k=0}^{n} (k+1)^{-1}$$

and

$$\sigma_n^* = \sum_{k=0}^{n} (n+1-k)^{-1} s_k / \log n.$$

Theorem: $|H|$ and $|H^*|$ are equivalent.

R. E. Williamson (Norwich, Vt.)

Mac Nerney, J. S. 6219

Characterization of regular Hausdorff moment sequences.

Proc. Amer. Math. Soc. **15** (1964), 366–368.

The following theorem was suggested to the author by a problem proposed by H. S. Shapiro [Amer. Math. Monthly **69** (1962), 1013]: In order that the infinite complex-number sequence μ, with $\mu_0 = 1$, be a regular Hausdorff moment sequence, it is necessary and sufficient that, for each continuous complex-valued function f on $[0, 1]$, the limit $L(f) = \lim_{n\to\infty} \sum_{k=0}^{n} (-1)^{n-k} f(k/n) C_{n,k} \Delta^{n-k}\mu_k$ exist, and in this case, $L(f) = f(1) \lim_{n\to\infty} \mu_n$. The solution of Shapiro's problem appears as the particular case $\mu_n = 1/2^n$. An equivalent condition is that

$$M(f) = \lim_{n\to\infty} \sum_{k=0}^{n} f(k/n) C_{n,k} \Delta^{n-k}\mu_k$$

exist, and in this case, $M(f) = \int_0^1 f\, d\phi$, where ϕ is a function of bounded variation having μ as its moment sequence.

H. S. Wall (Austin, Tex.)

Maddox, I. J. 6220

Some inclusion theorems.

Proc. Glasgow Math. Assoc. **6**, 161–168 (1964).

The author gives necessary and sufficient conditions for a sequence-to-sequence, or series-to-sequence, regular matrix to include the Riesz method $(R, \lambda, 1)$. Theorem 1: If $A = (a_{n\nu})$ is a sequence-to-sequence regular matrix, then $A \supset (R, \lambda, 1)$ if and only if

$$\sum_{\nu=0}^{\infty} \lambda_{\nu+1} |\Delta(a_{n\nu}/\Delta\lambda_\nu)| \leq M,$$

where M is a constant. This generalizes a result due to Lorentz [Trans. Roy. Soc. Canada Sect. III (3) **45** (1951), 19–32; MR **14**, 160]. Theorem 2: If A is a series-to-sequence matrix with $a_{n\nu} \to 1$ ($n \to \infty$; ν fixed), then $A \supset (R, \lambda, 1)$ if and only if (i) $|a_{n\nu}| \leq H_n \Lambda_\nu^{-1}$, where $\Lambda_\nu = \lambda_{\nu+1}/|\Delta\lambda_\nu|$ and H_n is a positive number depending on n, and

(ii) $$\sum \lambda_{\nu+1} |\Delta(\Delta a_{n\nu}/\Delta\lambda_\nu)| \leq M,$$

where M is a constant. Theorem 3: The series-to-sequence matrix A with $a_{n\nu} \to 1$ ($n \to \infty$; ν fixed) includes $(R, \lambda, 1)$, where $\Lambda_n = \lambda_{n+1}/(\lambda_{n+1} - \lambda_n)$ is unbounded if and only if the following conditions hold: (i) $|a_{n\nu}| \leq H_n \Lambda_\nu^{-1}$, where H_n is a constant depending on n, and (ii) there exists a sequence of functions $\{g_n(u)\}$ defined for $u \geq \lambda_0$ and such that $a_{n\nu} = \int_{\lambda_\nu}^{\infty} (u - \lambda_\nu)\, dg_n(u)$, with $\int_{\lambda_0}^{\infty} u |dg_n(u)| \leq M$, a constant.

Sherif, Soraya 6221

Tauberian classes and Tauberian theorems.

Quart. J. Math. Oxford Ser. (2) **15** (1964), 303–308.

Es werden neue Tauberсche Klassen eingeführt, von denen die umfangreichste C folgendermaßen definiert ist: Es gehört $s(e^y) \in C$, wenn es zu irgendeinem $\varepsilon > 0$ Konstanten $\mu = \mu(\varepsilon)$, $\lambda = \lambda(\varepsilon)$ mit $0 \leq \mu < 1 < \lambda$ und Funktionen $\theta = \theta(\varepsilon, x)$, $\alpha = \alpha(\varepsilon, x)$ mit $\alpha \to \infty$ für $x \to \infty$ derart gibt, daß $\mathrm{Re}[e^{i\theta} s(y)] \geq (1-\mu)|s(x)| - \varepsilon$ für $\alpha \leq y \leq \lambda\alpha$ und hinreichend große x gilt. Zahlreiche Sätze des Buches *Tauberian theorems* von H. R. Pitt [Oxford Univ. Press, London, 1958; MR **21** #5109] bleiben richtig, wenn man die dort auftretenden Tauberschen Klassen durch die neuen ersetzt. Beispielsweise gilt jetzt: Ist $s(y)$ (R, h)-limitierbar zum Wert 0 und ist $s(e^y) \in C$ mit $\liminf_{\varepsilon\to 0} [\varepsilon/(1-\mu(\varepsilon))] = 0$, so gilt $s(y) \to 0$.

L. Berg (Halle)

Wilansky, Albert 6222

Topological divisors of zero and Tauberian theorems.

Trans. Amer. Math. Soc. **113** (1964), 240–251.

Using mostly work of B. Yood [Ann. of Math. (2) **50** (1949), 486–503; MR **10**, 611], the author examines the algebra Γ of conservative matrices; the notation is the same as in the review of I. D. Berg's paper on the same subject [Proc. Amer. Math. Soc. **15** (1964), 648–652; MR **29** #2574]. The paper has a strongly eclectic cast, and the author's claim of "depth" for some of his results seems quite unjustified. The paper does give a useful summary of the present state of the theory of Γ.

Privalov, A. A. 6223

Interpolation on countable sets. (Russian)

Uspehi Mat. Nauk **19** (1964), no. 4 (118), 197–200.

In this paper the author defines an interpolation matrix to be an infinite triangular matrix of real numbers such that the k numbers in the kth row are distinct. He proves the following theorem: There exists a closed countable set F in $[-1, 1]$ with one limit point such that for any interpolation matrix M defined in F the order of increase of norms of interpolation polynomials is asymptotically not less than $\ln n$.

The norms referred to are defined by

$$L_n(M, F) = \max_{x\in F} \sum_{k=1}^{n} |l_{k,n}(x)|,$$

where $l_{k,n}(x)$ is the kth Lagrangian interpolation polynomial of degree $n-1$. The theorem shows that there exists a countable set F with interpolation behavior as "bad" as the entire interval $[-1, 1]$.

P. C. Hammer (Madison, Wis.)

Aramă, Oleg 6224

Sur quelques polynomes de type Bernstein.

Mathematica (Cluj) **4** (**27**) (1962), 205–224.

In dieser Arbeit führt der Verfasser frühere Untersuchungen [Mathematica (Cluj) **2** (**25**) (1960), 25–40; MR **22** #A1986b] über die Approximation von Funktionen durch Polynome vom Bernsteinschen Typ fort. Solche Polynome sind

$$B_n^{(k)}(x, f) = f(0) + \frac{x}{1!} f'(0) + \cdots + \frac{x^{k-1}}{(k-1)!} f^{(k-1)}(0) + \int_0^x \frac{(x-u)^{k-1}}{(k-1)!} B_n\left(u; \frac{d^k f}{dx^k}\right) du \quad (n = 1, 2, \cdots),$$

worin $B_n(x, F)$ die Bernsteinpolynome der Funktion F darstellen. Und zwar werden aus Konvexitätseigenschaften der Ableitungen von F für die Folge der abgeleiteten Polynome $B_n^{(k)}(x, f)$ interessante Monotonieeigenschaften gefolgert, mit deren Hilfe für eine Funktion

$f \in C^{n}[0, 1]$ für jedes $x \in [0, 1]$ die folgende Aussage gewonnen wird:

$$f(x) - B_m^{(k)}(x, f) = -\frac{x^{k+1}}{m}\left(\frac{k+2}{2} - x\right)[y_{m,1}^{(k)}, \cdots, y_{m,k+2}^{(k)}; f] \quad (m = 1, 2, \cdots).$$

Dabei ist $[y_{m,1}^{(k)}, \cdots, y_{m,k+2}^{(k)}; f]$ die dividierte Differenz der entsprechenden Werte aus $(0, 1)$. Ähnliche Ergebnisse werden für die Ableitungen von $f(x) - B_m^{(k)}(x, f)$, wie auch für den Ausdruck $B_{m+1}^{(k)}(x; f) - B_m^{(k)}(x; f)$ und dessen Ableitungen bewiesen.

Schließlich verallgemeinert der Autor dann seine Ergebnisse auf zwei Veränderliche.

Berg, Lothar 6225

Iterative Berechnung der Tschebyscheffschen Alternante für quadratische Polynome.

Z. Angew. Math. Mech. **44** (1964), 220–222.

Es sei $f(x)$ eine im reellen Intervall $[a, b]$ gegebene Funktion, für welche die dritte Ableitung $f'''(x)$ dort stetig und positiv ist. Gesucht ist das Polynom von höchstens zweitem Grad, welches $f(x)$ im Sinne von Tschebyscheff am besten approximiert. Die Alternante besteht aus den beiden Endpunkten a und b und aus zwei im Innern von $[a, b]$ gelegenen Punkten u und v. Zur Berechnung von u und v (aus denen leicht das beste Polynom bestimmt werden kann) gibt der Verfasser zwei iterative Methoden an, die von dem bisher üblichen Austauschverfahren wesentlich verschieden sind. Die Konvergenz beider Verfahren wird für den Fall bewiesen, daß das

$$\max_{a \le x \le b} f'''(x) < \frac{3}{2} \min_{a \le x \le b} f'''(x)$$

ist. Die erste Methode ist geometrisch interpretierbar und steht in Analogie zu dem (elementaren) Fall $n = 1$. An numerischen Beispielen zeigt sich die sehr gute Konvergenzgeschwindigkeit. Der Verfasser weist auf die prinzipielle Möglichkeit der Verallgemeinerung für $n > 2$ hin.

G. Meinardus (Clausthal-Zellerfeld)

Čuprigin, O. A. 6226

On the approximation of functions by interpolation polynomials with equally spaced nodes. (Russian)

Vesci Akad. Navuk BSSR Ser. Fiz.-Tèhn. Navuk **1964**, no. 3, 11–17.

Diese Arbeit ist eine Weiterführung einer Abhandlung von P. O. Runck [J. Reine Angew. Math. **208** (1961), 51–69; MR **26** #1994a]. Im Segment $[-1, +1]$ sei die äquidistante Knotenmatrix $x_i^{(n)} = -1 + 2in^{-1}$ gegeben, untersucht wird dann das Verhalten der Lebesgueschen Funktion $\lambda_n(x)$ in gewissen Teilintervallen. Ist $r > 0$ beliebig, und setzt man $t_n = r(n \log n)^{-1}$, so gibt es eine Konstante $c_r > 0$, für welche die Ungleichung $\lambda_n(x) < c_r$ unter den folgenden Bedingungen gilt: (a) bei geradem n für $x \in [-t_n, +t_n]$, (b) bei ungeradem n für $x \in [-n^{-1} - t_n, -n^{-1} + t_n]$ und $x \in [n^{-1} - t_n, n^{-1} + t_n]$, (c) bei jedem n für $x \in [-1, -1 + 2^{-n}r]$ und $x \in [1 - 2^{-n}r, 1]$.

Ist auch noch $k > 0$ beliebig, und setzt man

$$u_n = r\sqrt{(2n^{-1}(k \log n - \log \log n))}$$

so gilt in $[-u_n, +u_n]$ die Abschätzung $\lambda_n(x) = A(r)n^k$, wobei $A(r)$ nicht von n abhängt, und mit $v_n = 2^{-n}rn^{k+1}$ ist $\lambda_n(x) = B(r)n^k$ für $x \in [-1, -1 + v_n]$ und $x \in [1 - v_n, 1]$. Aus diesen Sätzen werden noch Folgerungen über die Güte der Approximation einer stetigen Funktion durch die äquidistante L-Interpolation in den betrachteten Teilintervallen (bei gegebenem Stetigkeitsmodul) gezogen.

Ehlich, H.; Zeller, K. 6227

Schwankung von Polynomen zwischen Gitterpunkten.

Math. Z. **86** (1964), 41–44.

Die Verfasser geben verschiedene Abschätzungen für den Maximalbetrag des Fehlerpolynoms, die manche bekannte Ergebnisse enthalten bzw. verschärfen. Mit der Abschätzung der Ableitung bzw. steilster Abstieg beweisen sie die folgenden Sätze: (I) Sei P ein Polynom vom Grade $\le n$ $(n > 2)$. Die natürliche Zahl m befriedige

$$\rho = n^2(n^2 - 1)/6m^2 < 1.$$

Aus $|P(x_\mu)| \le 1$ $(x_\mu = -1 + 2\mu/m, \mu = 0, 1, \cdots, n)$ folgt dann $|P(x)| \le 1/1 - \rho$ $(-1 \le x \le 1)$. (II) Sei P ein Polynom; es gelte grad $P \le n < m$ $(n, m \ge 0)$. Aus $|P(x_\mu)| \le 1$ $(x_\mu = \cos((2\mu - 1)\pi/2m); \mu = 1, 2, \cdots, m)$ folgt dann $|P(x)| \le 1/\cos(n\pi/2m)$ $(-1 \le x \le 1)$. (III) Sei T ein trigonometrisches Polynom und α eine reelle Zahl; es gelte grad $T \le n < m$ $(n, m \ge 0)$. Aus $|T(y_\mu)| \le 1$ $(y_\mu = \alpha + (\pi\mu/m)$; $\mu = 0, 1, \cdots, 2m - 1)$ folgt dann $|T(y)| \le 1/\cos(n\pi/2m)$.

R. G. Langebartel (Urbana, Ill.)

Malik, M. A. 6229

On extremal properties of the derivatives of polynomials and rational functions.

Canad. Math. Bull. **7** (1964), 121–131.

Let $f(z)$ be a rational function which is the quotient of polynomials of degrees m and n such that $f(z)$ has no zeros or poles inside the unit circle and $|f(z)| \le 1$ on $[-1, 1]$. The author shows that for $0 < \varepsilon < 1$ and $-1 + \varepsilon \le x \le 1 - \varepsilon$, the inequalities $|f'(x)| \le \varepsilon^{-1}[2(m + n)]^{1/2}$ and $|f''(x)| \le \varepsilon^{-2}[2(m + n)]^{3/4}$ are valid. These results are an improvement over a result of Erdős [Ann. of Math. (2) 41 (1940), 310–313; MR 1, 323], who considered only the first derivative and $f(z)$ a polynomial of degree n.

D. S. Greenstein (Evanston, Ill.)

Szegő, Gabor 6231

On a problem of the best approximation.

Abh. Math. Sem. Univ. Hamburg **27** (1964), 193–198.

A classical problem of Chebyshev is to minimize $\max|F(x)|$, $|x| \leq 1$, where

$$F(x) = (Ax^n + a_1x^{n-1} + \cdots + a_n)/q(x)$$

with given n and A and positive polynomial q of degree not exceeding n. The author finds that this problem can be solved easily by reducing it, via $x = \cos\theta$, to the corresponding problem for $G(\theta) = H(\theta)/h(\theta)$, where H and h are real trigonometric polynomials, the terms of highest order in H have prescribed coefficients, and h is positive. The solution is obtained by finding the particular G that assumes its maximum modulus $2n$ times with alternating signs. As an application the author shows that if $f(\theta)$ is continuous, positive and periodic, and $\mu_n(f)$ is the minimum of $\max f(\theta)|H(\theta)|$, where H runs through trigonometric polynomials of degree n with leading term $\cos n\theta$, then $\lim \mu_n(f)$ equals the geometric mean of f; there is a corresponding result for continuous functions f on $[0, 1]$.

On the local behavior of the rational Tschebyscheff operator.

Bull. Amer. Math. Soc. **70** (1964), 554–555.

Let $\mathfrak{R}(l, r)$ be the set of rational functions where the degrees of the numerator and denominator do not exceed l and r, respectively. If $R = p/q \in \mathfrak{R}(l, r)$ and p, q are relatively prime, then $d[R] = \min[l - \partial p, r - \partial q]$ is called the defect of R in $\mathfrak{R}(l, r)$. R is called degenerate if its defect is positive. Let $T[l, r; f]$ be the best (weighted) uniform approximation to $f \in C[a, b]$ from $\mathfrak{R}(l, r)$. Those f for which $T[l, r; f]$ is not degenerate are called normal. The author improves a recent result of Cheney and Loeb by stating Theorem 1: The operator $T[l, r; f]$ is continuous at f if and only if f is normal or belongs to $\mathfrak{R}(l, r)$.

A counterpart to this is given by Theorem 2. Given $f \in C[a, b]$. To every $\varepsilon > 0$, $\varepsilon_1 > 0$ one can find $\delta > 0$ such that $\|f - g\| < \delta$ implies that there is a finite number of intervals depending on g whose total length is less than ε_1 such that for all points of $[a, b]$ not lying in the said intervals the inequality $|T[l, r; f](x) - T[l, r; g](x)| < \varepsilon$ holds. Proofs will be given elsewhere.

Rice, John R. 6233

On the L_∞ Walsh arrays for $\Gamma(x)$ and Erfc(x).

Math. Comp. **18** (1964), 617–626.

The two functions may each be approximated in an appropriate range by a rational function of degree (n, m) (using an obvious notation). The author considers in each case the best L_∞ approximation of degree (n, m), that is, the approximation of that degree whose maximum difference from $f(x)$ in the range is the smallest. The optimum (n, m) pair for each $(n+m)$ value is noted, for $n+m = 1, 2, 3, \cdots, 15$. The striking practical result is observed that in the case of Erfc(x) in $[0, \infty]$, these optimum values follow a smooth path, while for $\Gamma(x)$ in $[2, 3]$ they are extremely erratic. This interesting phenomenon awaits explanation.

Copson, E. T. 6234

★Asymptotic expansions.

Cambridge Tracts in Mathematics and Mathematical Physics, No. 55.

Cambridge University Press, New York, 1965. vii + 120 *pp.* \$6.00.

This monograph is an exposition of the most commonly employed methods for the determination of the asymptotic expansions of functions. These methods are amply illustrated by establishing asymptotic expansions for a number of special functions such as the gamma function, error function, Fresnel integrals, Bessel functions, the Legendre polynomials, and related functions. The chapter headings are: (1) Introduction, (2) Preliminaries, (3) Integration by Parts, (4) The Method of Stationary Phase, (5) The Method of Laplace, (6) Watson's Lemma, (7) The Method of Steepest Descents, (8) The Saddle-Point Method, (9) Airy's Integral, (10) Uniform Asymptotic Expansions. The emphasis throughout is on technique, especially in Chapters 7 and 8 where the subject matter is treated heuristically. The Laplace approximation in Chapter 5 is proved as is Watson's lemma in Chapter 6, this lemma providing a powerful tool for establishing the asymptotic expansions of functions representable as Laplace integrals.

This book will inevitably invite comparisons with the two well-known monographs on asymptotic expansions: [1] A. Erdélyi, *Asymptotic expansions* [Dover, New York, 1956; MR **17**, 1202] and [2] N. G. de Bruijn, *Asymptotic methods in analysis* [North-Holland, Amsterdam, 1958, MR **20** #6003; second edition, 1961]. The subject matter and approach of the present book are very much like those of [1] with the inclusion of more recent material and more illustrative examples worked out in detail. However, the fundamentals of asymptotic expansions and series are treated more extensively in [1] than in the present book. Furthermore, [1] includes the application of asymptotic methods to differential equations—an important subject not treated by Copson. On the other hand, although the present book and [2] treat some of the same topics (in particular, the Laplace and saddle-point methods), [2] is of a higher level of mathematical exposition and very likely to be of greater appeal to the mathematician; moreover, the reviewer feels that there is no better introduction to the subject of asymptotics than [2].

Gosselin, R. P. 6237

On the approximation of L^p functions by trigonometric polynomials.

Fund. Math. **53** (1963/64), 121–134.

Let

$$I_{n,u}(x; f) = \frac{2}{2n+1} \sum_{j=0}^{2n} f(u + x_j) D_n(x - u - x_j),$$

$$x_j = \frac{2\pi j}{2n+1},$$

where D_n is the Dirichlet kernel. $I_{n,u}(x; f)$, which has been discussed by several authors, is a trigonometric polynomial which interpolates f at the fundamental points of interpolation translated by a parameter u.

$$\text{Condition } C_{\alpha,p}: \int_0^{2\pi} \int_0^{2\pi} \frac{|f(x+u) - f(x)|^p}{u^{1+\alpha}} \, du\, dx < \infty.$$

Theorem 1: If f satisfies $C_{\alpha,p}$ for $p > 1$ and $\alpha > (\sqrt{5} - 1)/2$, then for almost every (x, u), $I_{n,u}(x; f)$ converges to $f(x)$. If $p > 1$, but $\alpha < \frac{1}{2}$, then there is an f satisfying $C_{\alpha,p}$ for which $I_{n,u}(x; f)$ diverges for almost every (x, u).

Some applications are made to fractional integrals, and finally a concept, that of translation continuity, which seems natural in this context, is introduced.

The proofs are nicely arranged and use the concept of subadditive function in an interesting way.

Application of matrices to algebraic manipulations of trigonometric series. (Russian. Lithuanian and German summaries)

Litovsk. Mat. Sb. **3** (1963), no. 2, 193–207.

The author develops matrix algorithms, suitable for high-speed machines, for computing multiplication of Fourier series and division of trigonometric polynomials.

R. R. Goldberg (Evanston, Ill.)

Xie, Ting-fan [Hsieh, Ting-fan] 6239

On lacunary Fourier series.

Acta Math. Sinica **14** (1964), 312–318 (*Chinese*); *translated as Chinese Math.* **5** (1964), 340–345.

Let $f(x)$ have the Fourier series $\sum_{k=1}^{\infty} (a_k \cos n_k x + b_k \sin n_k x)$, where, for each k, $n_{k+1}/n_k \geq \lambda > 1$; let

$$\omega = \omega(f, x_0; \delta) = \sup_{|h| \leq \delta} |f(x_0 + h) - f(x_0)|;$$

and let

$$\omega_2 = \omega_2(f, \delta) = \max_{|h| \leq \delta} \max_{x} |f(x+h) + f(x-h) - 2f(x)|.$$

The author proves that if r is a positive integer, if $\phi(\delta)$ is positive and monotone increasing on $(0, \frac{1}{2})$, if $\eta^r \int_\eta^{1/2} \delta^{-r-1} \phi(\delta)\, d\delta \leq K_r \phi(\eta)$ $(0 < \eta \leq \frac{1}{2})$, and if at some point x_0, $\omega = O(\phi(\delta))$ as $\delta \to 0$, then $a_k, b_k = O(\phi(n_k^{-1}))$. The case $\phi(\delta) = \delta^\alpha$ improves on a result of Tomić [J. London Math. Soc. **37** (1962), 117–120; MR **24** #A3465]. Corollaries are that $f(x) \in \operatorname{Lip} \alpha$ $(0 < \alpha < 1)$ if and only if $\omega = O(\delta^\alpha)$ for some x_0, and that $f(x)$ is quasi-smooth if and only if $\omega = O(\delta)$ for some x_0. A simpler proof is given of a result due to Freud [Math. Z. **78** (1962), 252–262; MR **25** #2365] which, together with the above result, shows that $f(x)$ is smooth if and only if it has a finite derivative at some point x_0.

It is also shown that, for any $\beta > 0$, $\omega_2 = O(\delta|\log \delta|^{-\beta})$ if and only if $a_k, b_k = O(n_k^{-1}|\log n_k|^{-\beta})$. As corollaries (1) $\omega_2 = O(\delta|\log \delta|^{-\beta})$ if and only if $\omega = O(\delta|\log \delta|^{-\beta})$ at some point x_0; (2) using a result of Weiss and Zygmund [Nederl. Akad. Wetensch. Proc. Ser. A **62** (1959), 52–58; MR **21** #5849], if there is a point x_0 such that $\omega = O(\delta|\log \delta|^{-\beta})$ $(\beta > \frac{1}{2})$, then $f(x)$ is the indefinite integral of a function $g(x)$ which belongs to L^p for every $p \geq 1$.

P. Heywood (Edinburgh)

Robertson, M. M. 6240

Integrability of trigonometric series. II.

Math. Z. **85** (1964), 62–67.

As in Part I [same Z. **83** (1964), 119–122; MR **28** #5290] the author considers functions $f(x) = \frac{1}{2}\lambda_0 + \sum_1^\infty \lambda_n \cos nx$, $g(x) = \sum_1^\infty \lambda_n \sin nx$ which are "well behaved of order k"; by this is meant that the sequence $\{\lambda_n\}$ can be partitioned into k disjoint subsequences $\Lambda_i = \{\lambda_{nk+i}\}$ $(i = 1, \cdots, k)$, each of which ultimately increases or decreases to 0. He shows that, if $\phi(x, k, \gamma) = \prod_0^{[k/2]} (x - 2l\pi/k)^{-\gamma}$ and if $f(x)$ $[g(x)]$ is well behaved of order k, then when $p > 1$ and $1 - p < \gamma < 1$, $\{f(x)\}^p \phi(x, k, \gamma) \in L(0, \pi)$ $[\{g(x)\}^p \phi(x, k, \gamma) \in L(0, \pi)]$ if and only if $\sum n^{p+\gamma-2} |\lambda_n|^p$ converges. The corresponding result for $p = 1$ was proved by the author in Part I (in the review of which the series $\sum n^{\gamma-1}|\lambda_n|$ appeared as $\sum n^{-\gamma}|\lambda_n|$). The case $k = 1$ of the present theorem was previously dealt with by Yung-Ming Chen [ibid. **66** (1956), 9–12; MR **18**, 303; ibid. **68** (1957), 227–244; MR **19**, 1176].

H. Burkill (Sheffield)

Ciesielski, Z. 6241

On the orthonormal Franklin system.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 461–464.

For terminology and notation, see the author [Studia Math. **23** (1963), 141–157; MR **28** #419]. Put $\Delta_h x(t) = x(t+h) - x(t)$, $\Delta_h^2 x(t) = x(t+2h) - 2x(t+h) + x(t)$. For $x \in L_p\langle 0, 1\rangle$, $1 \leq p \leq \infty$, put $D_1(x, p, h) = \|\Delta_h x\|_p$ $(0 < h < 1)$,

$D_2(x, p, h) = \|\Delta_h{}^2 x\|_p$ $(0 < 2h < 1)$, where $\Delta_h x(u)$ is defined as 0 for $1 - h < u \leq 1$ and $\Delta_h{}^2 x(u) = 0$ for $1 - 2h < u \leq 1$. Now if φ is linear in each interval $\langle t_{i-1}, t_i \rangle$, where $0 = t_0 < t_1 < \cdots < t_n = 1$, and $\delta = \min\{t_i - t_{i-1} : 1 \leq i \leq n\}$, then, for $1 \leq p \leq \infty$, $D_1(\varphi, p, h) \leq 4 \min(h/\delta, 1/2)\|\varphi\|_p$ $(0 < h < 1)$, $D_2(\varphi, p, h) \leq 8[\min(h/\delta, 2^{-p(p+1)})]^{-1+1/p}\|\varphi\|_p$ $(0 < 2h < 1)$. For $x \in L_p\langle 0, 1\rangle$ $(1 \leq p \leq \infty)$, define $E_n{}^{(p)}(x)$ as the infimum of $\|x - \varphi\|_p$ over all functions φ of the preceding type; moreover, put

$$\omega_1{}^{(p)}(\delta; x) = \sup\{D_1(x, p, h) : 0 < h \leq \delta\} \quad (0 < \delta < 1),$$

$$\omega_2{}^{(p)}(\delta; x) = \sup\{D_2(x, p, h) : 0 < h \leq \delta\} \quad (0 < 2\delta < 1).$$

If $n = 2^m + k$, $1 \leq k \leq 2^m$, $t_i = i2^{-m-1}$ $(0 \leq i \leq 2k)$, $t_i = (i-k)2^{-m}$ $(2k+1 \leq i \leq n)$, $x \in L_p\langle 0, 1\rangle$, then $E_n{}^{(p)}(x) \leq \|x - S_n(x)\|_p \leq 4E_n{}^{(p)}(x) \leq 20\omega_1{}^{(p)}(1/n; x)$ for $n = 1, 2, \cdots$; moreover, $1 \leq p < \infty$ and $E_n{}^{(p)}(x) = O(1/n)$ imply $\omega_2{}^{(p)}(\delta; x) = O(\delta)$; $\omega_2{}^{(\infty)}(\delta; x) = O(\delta)$ implies $E_n{}^{(\infty)}(x) = O(1/n)$; $1 \leq p \leq \infty$, $0 < \alpha < 1$, $E_n{}^{(p)}(x) = O(n^{-\alpha})$ imply $\omega_1{}^{(p)}(\delta; x) = O(\delta^\alpha)$; the same statements are true if O is replaced by o. If $x \in L_p\langle 0, 1\rangle$, $1 \leq p \leq \infty$, $x = \sum a_n f_n$, $0 < \alpha < 1$, then the following conditions are equivalent: (i) $E_n{}^{(p)}(x) = O(n^{-\alpha})$, (ii) $\|x - S_n(x)\|_p = O(n^{-\alpha})$, (iii) $2^{m(1/2-1/p)}T_m(p, a) = O(2^{-\alpha m})$, (iv) $\omega_1{}^{(p)}(\delta; x) = O(\delta^\alpha)$, where $a = (a_0, a_1, \cdots)$ and

$$T_m(p, a) = \left(\sum_{2^m+1}^{2^{m+1}} |a_k|^p\right)^{1/p} \quad (1 \leq p < \infty)$$

and $T_m(\infty, a) = \max\{|a_k| : 2^m + 1 \leq k \leq 2^{m+1}\}$. The same is true if O is replaced by o. If $x \in L_p\langle 0, 1\rangle$, $1 \leq p \leq \infty$, and $\sum_{n=1}^\infty (1/n)E_n{}^{(p)}(x) < \infty$, then $\sum_{n=0}^\infty |a_n f_n(t)|$ converges in the L_p norm and also almost everywhere. Let $L_p{}^{(\alpha)}$ be, for $1 \leq p \leq \infty$, $0 < \alpha < 1$, the space of all $x \in L_p\langle 0, 1\rangle$ such that $\omega_1{}^{(p)}(\delta; x) = O(\delta^\alpha)$ with the norm

$$\|x\|_p{}^{(\alpha)} = \max(\|x\|_p, \sup\{D_1(x, p, h)h^{-\alpha} : 0 < h < 1\}),$$

$L_p{}^{(\alpha,0)}$ the subspace of $L_p{}^{(\alpha)}$ of all x such that $\omega_1{}^{(p)}(\delta; x) = o(\delta^\alpha)$, m_p the space of all real sequences $a = (a_0, a_1, \cdots)$ such that $T_m(p, a) = O(1)$ with the norm $\|a\| = \sup(|a_0|, |a_1|, T_m(p, a)$ $(m = 0, 1, \cdots))$, $m_p{}^{(0)}$ the subspace of the last space consisting of all a such that $T_m(p, a) = o(1)$. Then $L_p{}^{(\alpha)}$, $L_p{}^{(\alpha,0)}$, m_p, $m_p{}^{(0)}$ are Banach spaces and the Fourier-Franklin expansion

$$x = \sum_{n=0}^\infty a_n f_n{}^{(\alpha,p)}, \qquad a_n = \|f_n\|_p{}^{(\alpha)} \int_0^1 x(u)f_n(u)\,du,$$

where $f_n{}^{(\alpha,p)} = f_n/\|f_n\|_p{}^{(\alpha)}$, establishes an isomorphism of $L_p{}^{(\alpha)}$ onto m_p, respectively, of $L_p{}^{(\alpha,0)}$ onto $m_p{}^{(0)}$; moreover, $\{f_n{}^{(\alpha,p)}\}$ is a Schauder basis for $L_p{}^{(\alpha)}$. If $x \in L_1\langle 0, 1\rangle$, then $|\sum_{k=0}^n f_k(t)f_k(s)| \leq c_1 n e^{-c_0 n|t-s|}$ for all $t, s \in \langle 0, 1\rangle$ and $n = 1, 2, \cdots$, where c_0 and c_1 are absolute constants; moreover, the Fourier-Franklin expansion of x converges at every Lebesgue point of x. No proofs are given.

Á. Császár (Budapest)

Gapoškin, V. F. 6242

On the convergence of orthogonal series. (Russian)

Dokl. Akad. Nauk SSSR **159** (1964), 243–246.

Let $\{\varphi_n\}$ be a real orthonormal system with respect to a measure μ. The Rademacher-Menshov theorem states that $\sum a_n\varphi_n(x)$ converges almost everywhere if $\sum a_n{}^2 \log^2 n$ converges. By generalising the fundamental lemma on which the proof depends, the author obtains the following general result. Let $|\varphi_n(x)| \leq M_n$ outside E_n, where for each E of finite μ-measure we have $\sum \mu(E_n \cap E) < \infty$. Then $\sum a_n\varphi_n(x)$ converges almost everywhere if

$$\sum a_n{}^2 \log^2\left(\sum_{k=1}^n |a_k| M_k + 1\right) < \infty.$$

A number of corollaries follow; in particular, if the φ_n are uniformly bounded, then $\sum a_k{}^2 \log^2(\sum_{k=1}^n |a_k| + 1) < \infty$ implies convergence almost everywhere. There are applications to the order of magnitude of partial sums and to (generalized) lacunary series.

R. P. Boas, Jr. (Evanston, Ill.)

Fomin, G. A. 6243

On linear methods of summability of Fourier series. (Russian)

Mat. Sb. (*N.S.*) **65** (**107**) (1964), 144–152.

Soit défini par la matrice triangulaire $\|\lambda_k{}^{(n)}\|$, $\lambda_0{}^{(n)} = 1$, $\lambda_{n+1}^{(n)} = 0$, $\Delta\lambda_k{}^{(n)} = \lambda_k{}^{(n)} - \lambda_{k+1}^{(n)}$, $k = 0, 1, \cdots, n-1$, un procédé régulier de sommation de la série de Fourier de $f(x) \in C[0, 2\pi]$ au moyen de l'opérateur

$$L_n(f; x) = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x+t)U_n(t)\,dt,$$

$$U_n(t) = \frac{1}{2} + \sum_{k=1}^n \lambda_k{}^{(n)} \cos kt.$$

La plus générale condition suffisante, portant sur $\lambda_k{}^{(n)}$ telle que $L_n(f; x) \to f(x) \in C[0, 2\pi]$, $n \to \infty$, a été donnée par A. V. Efimov [Izv. Akad. Nauk SSSR Ser. Mat. **24** (1960), 743–756; MR **23** #A1204]. L'auteur donne ici les nouvelles conditions qui ne sont pas contenues dans cette condition. Théorème 2: $L_n(f; x) \to f(x) \in C[0, 2\pi]$, $n \to \infty$, si

$$n \sum_0^n (\Delta\lambda_k{}^{(n)})^2 = O(1).$$

Théorème 7: Soit $\phi(x)$ continue sur $[0, 1]$ et à variation bornée, $\phi(0) = 1$, $\phi(1) \neq 0$, on a alors

$$\|L_n\| = \pi^{-1}\int_{-\pi}^{\pi}\left|\frac{1}{2} + \sum_{k=1}^n \phi\left(\frac{k}{n+1}\right)\cos kt\right| dt > C\log n,$$

$$C > 0.$$

Théorème 9. Soit la matrice $\|\lambda_k{}^{(n)}\|$ telle qu'il existe $m_n < n$ avec $m_n \sum_0^{m_n} (\Delta\lambda_k{}^{(n)})^2 = O(1)$, $m_n \to \infty$, $\Delta\lambda_{m_n}{}^{(n)} = \lambda_{m_n}{}^{(n)}$, $n = 1, 2, \cdots$, et $\sum_{m_n+1}^n (\lambda_k{}^{(n)})^2 = O(1)$, alors $L_n(f; x) \to f(x) \in C[0, 2\pi]$, $n \to \infty$, $x \in [0, 2\pi]$.

Jakimovski, Amnon 6244

Analytic continuation and summability of series of Legendre polynomials.

Quart. J. Math. Oxford Ser. (2) **15** (1964), 289–302.

Let (*) $\sum a_n P_n(z)$ be the Neumann series associated with a function $f(z)$ holomorphic in a domain containing the closed interval $-1 \leq \mathrm{Re}(z) \leq 1$. The reviewer and J. P. King [J. Analyse Math. **10** (1962/63), 139–152; MR **28** #1421] discussed the application of the Taylor and Lototsky transforms to the sequence of partial sums of (*). In the present paper the author proves some very general theorems (in terms of the generating domain D of the matrix A) for the summability of the sequence of partial sums of (*).

V. F. Cowling (New Brunswick, N.J.)

Leindler, László 6245

Über die de la Vallée-Poussinschen Mittel allgemeiner Orthogonalreihen.

Publ. Math. Debrecen **10** (1963), 274–282.

Let $\{\varphi_n(x)\}$ be an orthonormal sequence of functions on a finite interval, and let $\sum c_n\varphi_n(x)$ be the Fourier expansion of a function f. The author considers the size of $V_n(x)$ and $V_n(x)-f(x)$ under various conditions, where $V_n(x)=[s_n(x)+\cdots+s_{2n-1}(x)]/n$ is the delayed mean of de La Vallée Poussin. Typical theorems are as follows. Let $\mu_n\le\mu_{n+1}$ and $\sum_{s=0}^{k}\mu_{2^s}{}^2=O(\mu_{2^k}{}^2)$ and assume $\sum c_n{}^2\mu_n{}^2<\infty$. Then, $V_n(x)-f(x)=o_x(1/\mu_n)$ a.e. Two interesting examples are $\mu_n=n^\gamma$, $\gamma>0$, and $\mu_n=q^n$, $q>1$.

Let $\{l_n\}$ be positive, monotone non-decreasing to infinity and let $l_{2^n+1}=l_{2^n+2}=\cdots=l_{2^{n+1}}$. Then, if $\sum c_n{}^2l_n{}^{-2}<\infty$ and $\sum c_nl_n{}^{-1}\varphi_n(x)$ is $(C,1)$ summable a.e. on a set E, $V_n(x)=o_x(l_{2n})$ a.e. on E, where $V_n(x)$ is the delayed mean of $\sum c_n\varphi_n(x)$.

In an earlier paper [Acta Sci. Math. (Szeged) **24** (1963), 129–138; MR **27** #2792], the author has found similar theorems for Riesz means. *R. A. Askey* (Madison, Wis.)

Rubinštein, A. I. 6246

On ω-lacunary series and functions of the classes H^ω. (Russian)

Mat. Sb. (*N.S.*) **65** (**107**) (1964), 239–271.

Let ω be a real-valued continuous function on some interval $[0,h_0]$ with the following properties: $\omega(0)=0$, $\omega(h)\uparrow$, $\omega(h_1+h_2)\le\omega(h_1)+\omega(h_2)$. For such a function let H^ω be the set of 2π-periodic complex-valued functions f on the real line for which there exists a real number A, depending only on f, such that $|f(x+h)-f(x)|\le A\omega(|h|)$ for all x and h. The author investigates Fourier series, Fourier coefficients and properties of functions in H^ω. In the following let ω always fulfill the additional condition $\lim_{t\to+0}t^{-1}\omega(t)=\infty$, and let it be convex upwards. An increasing sequence of natural numbers $\{n_k\}$ $(k=1,2,\cdots)$ is called ω-lacunary if

$$(1)\qquad \sum_{k=N}^{\infty}\omega(n_k{}^{-1})=O[\omega(n_N{}^{-1})]$$

and

$$(2)\qquad \sum_{k=1}^{N}n_k\omega(n_k{}^{-1})=O[n_N\omega(n_N{}^{-1})]$$

$(N=1,2,\cdots)$. A trigonometric series $\sum_{k=1}^{\infty}(a_k\cos n_kx+b_k\sin n_kx)$ is called ω-lacunary if $\{n_k\}$ is an ω-lacunary sequence.

The following statements are proved, and they are typical. (i) If an increasing sequence of natural numbers $\{n_k\}$ fulfills (1) or (2), then it can be decomposed into a finite number of ordinary lacunary sequences $\{n_k{}^{(i)}\}$, i.e., such that $n_{k+1}^{(i)}/n_k{}^{(i)}\ge\lambda_i>1$ $(i=1,2,\cdots,l)$. (ii) Let f be a continuous function with an ω-lacunary Fourier series. Then $f\in H^\omega$ if and only if the Fourier coefficients of f are of order $O[\omega(n^{-1})]$. (iii) Let $f\in H^\omega$ with Fourier coefficients a_k, b_k. Then $(a_{n_k}{}^2+b_{n_k}{}^2)^{1/2}\ge c\omega(n_k{}^{-1})$ (c an arbitrary constant >0) implies that $\{n_k\}$ is ω-lacunary. (iv) Let $f(x)\sim\sum a_n\cos nx$ with $f\in H^\omega$ and $a_n\ge0$. Then

$$(3)\qquad \sum_{k=n}^{\infty}a_k=O[\omega(n^{-1})]$$

and

$$n^{-1}\sum_{k=1}^{n}ka_k=O\left[n^{-1}\int_{n^{-1}}^{\delta_0}\frac{\omega(t)}{t^2}\,dt\right],$$

where $\delta_0>0$ is fixed. Conversely, if ω is such that $\delta\int_\delta^{\delta_0}t^{-2}\omega(t)\,dt=O[\omega(\delta)]$ $(\delta\to+0)$ and $a_k\ge0$ $(k=1,2,\cdots)$, then (3) implies $f\in H^\omega$ for $f(x)\sim\sum a_k\cos kx$.

The last theorem implies partly a statement of Lorentz [Math. Z. **51** (1948), 135–149; MR **10**, 33]: Let $\sum a_k\cos kx\sim f(x)$ with $a_k\downarrow0$. Then $f\in\operatorname{Lip}\alpha$ $(0<\alpha<1)$ if and only if $a_n=O(n^{-1-\alpha})$ (Lorentz proved such a statement also for odd functions). A generalization of a result of Loud [Proc. Amer. Math. Soc. **2** (1951), 358–360; MR **13**, 218] is the following: (v) There exists a pair of conjugate functions $f,\tilde f\in H^\omega$, i.e., functions f and $\tilde f$ belonging to Fourier series conjugate to each other, such that in $[0,2\pi]$ $\limsup_{h\to0}|(f(x+h)-f(x))/\omega(|h|)|\ge c$, and correspondingly for $\tilde f$. Here c is a certain positive constant. (vi) Let $\Lambda=\|\lambda_k{}^{(n)}\|$ be a triangular matrix. If there exists an increasing sequence of natural numbers $\{n_k\}$ such that

$$\sum_{k=1}^{N-1}|1-\lambda_{n_k}{}^{(n_N-1)}|\omega(n_k{}^{-1})=o[\omega(n_N{}^{-1})],$$

then there exists a pair of conjugate functions $f,\tilde f\in H^\omega$ (see above) such that almost everywhere in $[0,2\pi]$

$$\limsup_{n\to\infty}[\omega(n^{-1})]^{-1}\left|f(x)-\sum_{k=1}^{n}\lambda_k{}^{(n)}(a_k\cos kx+b_k\sin kx)\right|>c,$$

and correspondingly for $\tilde f$. Here c is a certain positive constant. Statements of similar type for various summability methods such as the (C,α) method, Abel's method and de La Vallée Poussin's method conclude the paper.

{In the literature under [9] "Lond" should be replaced by "Loud".} *G. Goes* (Chicago, Ill.)

Tomić, M. 6247

Sur un critère pour la convergence des séries de Fourier dans un point fixe.

Bull. Acad. Serbe Sci. Arts Cl. Sci. Math. Natur. Sci. Math. **31** (1963), no. 4, 23–27.

Let the Fourier series of $f(x)$ be designated by

$$S(f)=a_0+\sum_{n=1}^{\infty}(a_n\sin nx+b_n\cos nx).$$

A well-known theorem of Hardy and Littlewood states that if

$$(1)\qquad f(x_0\pm h)-f(x_0)=o(|\log h|^{-1}),\qquad h\to0,$$

and

$$(2)\qquad |a_n|=O(n^{-r}),\qquad |b_n|=O(n^{-r})$$

for some $r>0$, then $S(f)$ converges at x_0. A positive function $L(u)$, defined for $0<u<\varepsilon$, is said to be slowly increasing at 0 if for all δ, $L(u)u^\delta$ decreases and $L(u)u^{-\delta}$ increases as $u\to0$. The following theorems are proved. Theorem 1: If the function $f(x)$ satisfies at x_0 the condition

$$(3)\quad f(x_0+t)+f(x_0-t)-2f(x_0)=\varphi(x_0,t)=\varphi(t)\to0,\quad t\to0,$$

where $\varphi(t)$ is a slowly increasing function as defined above, and if

$$\sup|f(x+h)-f(x)|=\omega(\delta)\to0,\qquad \delta\to0,\quad x\in(0,2\pi),\quad 0\le h\le\delta,$$

then $s_n(x_0)\to f(x_0)$, $n\to\infty$.

Theorem 2: If $f(x)$ satisfies condition (3) and if $S(f)$ has infinitely many gaps (n_{k+1}, n_k) of Fabry type, i.e., $n_{k+1}-n_k\to\infty$, then $s_{n_k}(x_0)\to f(x_0)$.

Griffith, James L. 6249

On the Gibbs' phenomenon in n-dimensional Fourier transforms.

J. Proc. Roy. Soc. New South Wales **97**, 163–173 (1964).

Author's summary: "It is shown that with the simple inversion formula, the Hankel transform exhibits a Gibbs' phenomenon at a point of discontinuity of the same magnitude as in the cases of the finite Fourier and one-dimensional Fourier transforms. In the case of the n-dimensional Fourier transform we must add reasonably heavy restrictions in order that the simple inversion formula should converge. When we do this we find that this transform will exhibit the Gibbs' phenomenon. In the simplest cases this magnitude will be equal to that in the two transforms mentioned above."
E. M. Stein (Chicago, Ill.)

Rajagopalan, M. 6250

Fourier transform in locally compact groups.

Acta Sci. Math. (Szeged) **25** (1964), 86–89.

I. E. Segal [same Acta **12** (1950), 157–161; MR **12**, 188; errata, MR **12**, 1002] proved that if the Fourier transformation on a commutative locally compact group G maps $L_1(G)$ onto $C_0(\hat G)$, then G is finite, and stated without proof that the analogue for noncommutative groups holds; this is proved by the author in the sense that if T_f is the operator $g\to f*g$ on $L_2(G)$, for an $f\in L_1(G)$, then $L_1(G)$ is complete under the norm $\|T_f\|$ if and only if G is finite. In the course of the proof it is shown that an extremally disconnected G is discrete and that a C^* algebra is weakly sequentially complete if and only if it is finite-dimensional. The author also proves a conjecture of Segal that if, for locally compact commutative G, the Fourier transform maps $L^p(G)$, $1<p<2$, onto the whole of $L^{p'}(\hat G)$, then G is finite.

Sur la transformée de Fourier-Carleman d'une fonction presque périodique de spectre donné.

C. R. Acad. Sci. Paris **258** (1964), 6049–6051.

Let $\Lambda=(\lambda_j)$ be an increasing sequence of positive real numbers such that $\lambda_j\to\infty$ and $\lim\sup(j/\lambda_j)<\infty$; put $C(w)=\prod_1^\infty(1-w^2/\lambda_j^2)$. Then Λ is called a (P) sequence if $1/C(w)$ is the Fourier-Carleman transform of an almost periodic function, all derivatives of which exist and are almost periodic [see J.-P. Kahane, Ann. Inst. Fourier (Grenoble) **5** (1953/54), 39–130; MR **17**, 732]. The proof of the following result is indicated. If

$$a_k=\frac{k\lambda_{k+1}-(k+1)\lambda_k}{\lambda_{k+1}-\lambda_k},$$

then (i) $\lim a_k=\infty$ implies that Λ is a (P) sequence, and (ii) $\lim\sup a_k<\infty$ implies that Λ is not a (P) sequence. A less simple condition, both necessary and sufficient for Λ to be a (P) sequence, is also given.

Bochner, S. 6252

Continuous mappings of almost automorphic and almost periodic functions.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 907–910.

The author gives his own proof of a counterexample, communicated to him by H. Furstenberg. If θ is any non-rational real number, then

$$\varphi(n)=\operatorname{signum}(\cos 2\pi n\theta),\qquad -\infty<n<\infty,$$

is almost automorphic, but not almost periodic, on the additive group of integers. The proof contains ingredients of a general nature.
E. Følner (Copenhagen)

Hartman, S.; Ryll-Nardzewski, C. 6253

Almost periodic extensions of functions.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **11** (1963), 427–429.

For this discussion, any point set S on the real line such that every bounded uniformly continuous function on S can be extended to a uniformly almost periodic function will be called an I-set. Previous results of Hartman [Colloq. Math. **8** (1961), 99–101; MR **23** #A3416] and Mycielski [ibid. **8** (1961), 95–97; MR **23** #A3415] exhibit countable sets which are not I-sets and countable sets which are I-sets. In the present paper, the authors announce a theorem affirming the existence of I-sets which are unbounded and the union of an infinite collection of disjoint intervals. They say that the proof depends mainly on the fact that certain sequences are I-sets if and only if their closures in the Bohr compactification of the real line are homeomorphic to the Stone-Čech compactification of the integers.

Kachroo, I. C. 6254

On the Borel summability of double Fourier series.

Rend. Accad. Sci. Fis. Mat. Napoli (4) **30** (1963), 29–33.

The author proves that the double Fourier series of a Lebesgue integrable periodic function on $(-\pi,\pi;-\pi,\pi)$ is summable by Borel exponential means to S at (x,y) if

$$\int_0^u\int_0^v|\Phi(s,t)|\,ds\,dt=o(uv/\log u^{-1}\log v^{-1}),$$

$$\int_0^v dt\left|\int_0^u\Phi(s,t)\,ds\right|=o(u/\log u^{-1})$$

and

$$\int_0^u ds\left|\int_0^v\Phi(s,t)\,dt\right|=o(v/\log v^{-1})\quad\text{as } u,v\to+0,$$

where

$$\Phi(s, t) = \tfrac{1}{4}[f(x+u, y+v) + f(x+u, y-v) + f(x-u, y+v) + f(x-u, y-v) - 4S],$$

thus generalizing a theorem of Sahney [Boll. Un. Mat. Ital. (3) 16 (1961), 156–163; MR 25 #391].

J. Mitchell (Madison, Wis.)

Beurling, Arne 6255

A critical topology in harmonic analysis on semigroups.

Acta Math. 112 (1964), 215–228.

Let S denote a discrete Abelian cancellation semi-group with irreducible zero element, let $\le$ denote the natural partial ordering of S, and let ω denote a positive real-valued function defined on S such that $\omega(y) \le 2\omega(x)$ whenever $y \le 2x$ and such that $\sum_{x \in S} e^{-\lambda_0 \omega(x)} \le 1$ for some positive λ_0. For each positive real number λ, let $A(\lambda)$ be the space of all complex functions f on S such that $\|f\|_\lambda = \sup_{x \in S} |f(x)| e^{-\lambda\omega(x)} < \infty$, and let $A = \bigcup \{A(\lambda) : \lambda > 0\}$ with the inductive limit topology. The dual space A' of A is identified with the set of complex functions φ on S such that, for all $\lambda > 0$, $\|\varphi\|_\lambda' = \sum |\varphi(x)| e^{\lambda\omega(x)} < \infty$, by way of the bilinear form $(f, \varphi) = \sum f(x)\varphi(x)$. The set of characters on S that belong to A' is denoted by $\chi_{A'}$, and the Laplace transform $\hat{f}$ of an element f of A is defined on $\chi_{A'}$ by $\hat{f}(\xi) = (f, \xi)$. Given τ in S, the shift operator T_τ is defined on A by $T_\tau f(x) = f(x-\tau)$ $(\tau \le x)$, $T_\tau f(x) = 0$ $(\tau \not\le x)$; and the closed linear hull in A of the set $\{T_\tau f : \tau \in S\}$ is denoted by A_f. The closure theorem is said to hold in A if $A_f = A$ whenever the Laplace transform of f vanishes nowhere on $\chi_{A'}$. It is proved that if the closure theorem holds in A, then the series $\sum_{n=1}^\infty n^{-3/2}\omega(nx)$ diverges for each non-zero x in S. For a result in the opposite direction, restrictions on the form of the function ω are needed. Suppose that ω is of the form $\psi \circ \theta$, where θ is an additive real function on S such that $\theta(x) \to +\infty$ as $x \to \infty$, and $\psi(r)$ is a positive increasing function of r for $r \ge 0$, is a convex function of $\log r$, and $c \log r \le \psi(r) = o(r)$ as $r \to \infty$. Under these conditions, it is proved that if $\sum_{n=1}^\infty n^{-3/2}\omega(nx)$ diverges for each non-zero x in S, then the closure theorem holds in A.

Churchill, R. V. 6258

Integral transforms associated with boundary conditions of third type.

Contributions to Differential Equations 3 (1964), 387–398.

This paper is concerned with boundary-value problems in $U(x, y)$ of the form

$$\mathscr{Y}_1[U_{xx}(x,y)] + \mathscr{Y}_2[U_{yy}(x,y)] = R(x,y) \qquad (x > 0,\ y_1 < y < y_2),$$

with $\mathscr{Y}_i$ $(i = 1, 2)$ linear differential operators of the type $\mathscr{Y}_i = \sum_{j=0}^{m} a_{ij}(y)\partial^j/\partial y^j$ on a bounded or unbounded interval $y_1 < y < y_2$, together with the requirement that U be bounded over the domain, satisfy at $x = 0$ a boundary condition of the "third type"

$$U_x(0, y) - hU(0, y) = Q(y) \qquad (h > 0),$$

and boundary conditions with respect to y of the form $B_i[U] = P_i(x)$ when $y = y_i$, where $B_i[U]$ is some linear combination with constant coefficients of $U(x, y_i)$ and the partial derivatives of U with respect to y are evaluated at $y = y_i$. The author presents two procedures for the solution of such boundary-value problems. The first method involves an integral transform of the solution of a corresponding problem in $V(x, y) = U_x(x, y) - hU(x, y)$, and the problem in V adapted to solution by the Fourier sine transformation with respect to x. The second method uses a modified Fourier integral transformation with respect to x designed for such problems, and for which the author derives a convolution formula; the second method is illustrated by the solution of a simple diffusion problem.

Mainra, V. P. 6259

On self-reciprocal functions.

Bull. Calcutta Math. Soc. 55 (1963), 41–49.

Consider the transform

$$\omega^{\lambda}_{\mu,\nu}(x) = \int_0^\infty \omega_{\mu,\nu}(xy) J_\lambda(y) y^{1/2}\,dy, \tag{1}$$

where

$$\omega_{\mu,\nu}(x) = (x)^{1/2} \int_0^\infty J_\mu(t) J_\nu(x/t) t^{-1}\,dt. \tag{2}$$

The author generalizes (1) to $m+n$ parameters and derives a number of formulas and relations therefrom. In addition, certain theorems on self-reciprocal functions belonging to a certain class are proved.

E. J. Scott (Urbana, Ill.)

Debnath, L. 6260

On Jacobi transform.

Bull. Calcutta Math. Soc. 55 (1963), 113–120.

The paper treats the operational calculus of the integral transformation $\int_{-1}^{1} p(x)P_n^{(\alpha,\beta)}(x)F(x)\,dx$ of functions F on the interval $(-1, 1)$, where $p(x) = (1-x)^\alpha(1+x)^\beta$, $\alpha > -1$, $\beta > -1$, and $P_n^{(\alpha,\beta)}(x)$ is the Jacobi polynomial of degree n.

The author presents the transformation of the basic differential form $[p(x)]^{-1}(d/dx)[(1-x)^{\alpha+1}(1+x)^{\beta+1}F'(x)]$, the transformation of the inverse of that form, the series representing the inverse of the Jacobi integral transformation, transforms of some particular functions, and special cases of the transformation. His treatment is different from, and more complete than, that given earlier by E. J. Scott [Quart. J. Math. Oxford Ser. (2) **4** (1953), 36–40; MR **14**, 869]. *R. V. Churchill* (Ann Arbor, Mich.)

A remark on Mercer's paper, "On integral transform pairs arising from second-order differential equations". (Russian)

Sibirsk. Mat. Ž. **5** (1964), 1200–1202.

Mercer [Proc. Edinburgh Math. Soc. (2) **12** (1962), 63–68; MR **25** #5350] has shown that pairs of integral transforms can be associated with certain homogeneous linear differential equations. In this article, the author shows that Mercer's method can be extended to certain inhomogeneous differential equations. *P. G. Rooney* (Toronto, Ont.)

Norris, D. O. 6263

A topology for Mikusiński operators.

Studia Math. **24** (1964), 245–255.

In der Mikusińskischen Operatorenrechnung bereitet die Einführung einer geeigneten Topologie für Operatoren bekanntlich gewisse Schwierigkeiten. Hier wird ein neuer Weg zur Definition der Konvergenz von Operatorfolgen eingeschlagen, wobei zugleich eine Modifikation von Mikusińskis Definition zugrundegelegt wird. Mit C wird die Menge aller komplexwertigen stetigen Funktionen $a(t)$ $(-\infty<t<+\infty)$ bezeichnet, welche für $t\le\sigma(a)$ identisch verschwinden. Im Unterschied zu der Operatorenrechnung von Mikusiński werden also hier Funktionen nicht nur für nichtnegative Argumente betrachtet, aber die Bedingung des Verschwindens auf einem linken Halbstrahl läuft im wesentlichen auf dasselbe hinaus. Addition und Multiplikation mit Skalaren werden in C wie üblich definiert; das Produkt zweier Elemente a und b von C wird durch die Faltung definiert

$$(a*b)(t)=\int_{-\infty}^{+\infty}a(\tau)b(t-\tau)\,d\tau.$$

Man sieht sofort, daß diese Operationen nicht aus C hinausführen. Es ist auch klar, daß der Integrand des Faltungsintegrals nur in einem endlichen Intervall von Null verschieden ist. Es werden außerdem noch der Raum L der in jedem endlichen Intervall integrablen, links verschwindenden Funktionen und der Unterraum D aller unendlich oft differenzierbaren Funktionen von C eingeführt. D ist eine Subalgebra der Algebra C, ebenso $C*L\subset C$ und $D*L\subset D$. Der Verfasser betrachtet sodann allgemein das Problem der Einführung einer Topologie in einer Subalgebra eines Quotientenkörpers eines Integritätsbereichs, für den Fall, daß der Integritätsbereich bereits eine Topologie trägt, welche durch eine Familie von Seminormen definiert ist. Die daraus natürlicherweise folgende Theorie wird auf die Operatorenrechnung angewendet. Es sei Q der Quotientenkörper von C; in C selbst wird die Topologie der kompakten Konvergenz eingeführt, welche sich auch durch eine Familie von Seminormen definieren läßt (Suprema der Absolutbeträge in kompakten Intervallen). S bezeichne die Subalgebra aller a aus Q mit der Eigenschaft, daß $a*D\subset D$.

An einem Beispiel wird gezeigt, daß die hier erzeugte Topologie in S nicht mit der Topologie von C verträglich ist. Ist aber P eine Menge von allen Elementen $c\in C$ für die $\sigma(c)\ge\tau$, so ist die Konvergenz in S bezüglich P verträglich mit der Konvergenz in C. Es wird sodann der Vergleich mit Mikusińskis Konvergenzdefinition durchgeführt, wobei sich für alle praktisch wirklich auftretenden Operatorfolgen Übereinstimmung ergibt. Es zeigt sich ferner, daß Operatorfunktionen im Sinne von Mikusiński nur dann stetig sind, wenn sie in der S-Topologie stetig sind. Entsprechendes gilt für die Differenzierbarkeit. *D. INTEGRAL EQUATIONS

See also 6163, 6164, 6165, 6172.

Maroni, Pascal 6265

Sur les solutions de l'équation de Milne généralisée.

C. R. Acad. Sci. Paris **259** (1964), 501–503.

The integral equation considered is

$$\mathcal{F}(t)=\int_0^\infty K(|t-\theta|)\mathcal{F}(\theta)\,d\theta\qquad(t\ge0),$$

where $K(t)$ satisfies certain conditions we shall not reproduce. A special case is Milne's equation from radiative transfer theory. Similar generalizations of Milne's equation have been studied by a number of writers [cf. I. W. Busbridge, *The mathematics of radiative transfer*, Cambridge Univ. Press, New York, 1960].

Solutions are sought which are measurable, bounded on each $[a,b]\subset(0,\infty)$, and satisfy certain asymptotic conditions. A direct study of the integral operator shows that

such a solution is necessarily twice continuously differentiable on each $[a, b] \subset (0, \infty)$. Transform methods yield a solution unique up to a constant factor. Various identities are given. There are no proofs.

On the growth of eigenvalues of a linear integral equation. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1022–1025.

Asymptotic estimates are given for the growth of proper values of the integral equation $y(x) = \lambda \int_0^1 K(x, t)y(t)\,dt$ for $K(x, t)$ smooth except at $(0, 0)$ and $(0, 1)$, and for $K(x, t)$ with Green's function type singularities on the line $x = t$.

L. B. Rall (Madison, Wis.)

Hayashi, Yoshio 6268

On some singular integral equations. I.

Proc. Japan Acad. **40** (1964), 323–328.

This note concerns solutions of singular integral equations of the type considered by Mushelišvili in his book *Singular integral equations* [Noordhoff, Groningen, 1953; MR **15**, 434]. The theorems are of two types. First a contraction mapping procedure is given for equations of first kind. It is shown that addition and subtraction of a suitable function modifies the reduced Fredholm operator (in Mushelišvili's terminology) so as to make it a contraction. Then the method of successive approximations is valid. The second result is that an equation of second kind can be reduced to one of first kind. Essentially no proofs are given, and this makes the results difficult to follow.

R. C. MacCamy (Pittsburgh, Pa.)

Kumano-go, Hitoshi 6269

On a definition of singular integral operators. I, II.

Proc. Japan Acad. **40** (1964), 368–373; *ibid.* **40** (1964), 374–378.

The author considers singular integral operators H, in the sense of Calderón and Zygmund [see A. P. Calderón and A. Zygmund, Amer. J. Math. **79** (1957), 901–921; MR **20** #7196]. Instead of requiring the symbols $\sigma(H)(x, \eta)$ to be homogeneous, it is assumed that $\sigma(H)(x, \eta)$ is analytic in η. Part I is devoted to the definition of singular integral operators H and to proving certain lemmas. In Part II the author derives the theorems of Calderón and Zygmund for singular integral operators as defined in Part I. H is shown to be a bounded operator in L_2. The operators $H_1 \circ H_2$ and H^* are defined, and the analogous theorems relating H^* with H^* and $H_1 \circ H_2$ with H_1H_2 are proved.

L. M. Sibner (Stanford, Calif.)

Widom, Harold 6270

Asymptotic behavior of the eigenvalues of certain integral equations. II.

Arch. Rational Mech. Anal. **17** (1964), 215–229.

The author continues and partly generalizes his work in Trans. Amer. Math. Soc. **109** (1963), 278–295 [MR **27** #5101]. Let $K(\xi)$ $(-\infty < \xi < \infty)$ be bounded, non-negative, and even, and suppose that $K(\xi) \to 0$ as $\xi \to \infty$. For $f \in L_2(-1, 1)$, let $F(\xi) = \int_{-1}^{1} e^{i\xi x} f(x)\,dx$, and let $T(K)f$ be the restriction to $(-1, 1)$ of the inverse Fourier transform of $K(\xi)F(\xi)$. $T(K)$ is positive definite (for $K \neq 0$ a.e.) and completely continuous. Order its eigenvalues $\lambda_0(K) \geq \lambda_1(K) \geq \cdots > 0$. Write $K(\xi) = e^{-\Gamma(\xi)}$. The author proves the following theorems. Theorem I: If Γ is continuous, increasing for large ξ, and $\Gamma(\xi)/\xi \to 0$ as $\xi \to \infty$, then $\lambda_n(K) \sim K(n\pi/2 + o(n))$ as $n \to \infty$. Theorem II: If $\Gamma(\xi) \sim \alpha\xi$ $(0 < \alpha < \infty)$, then $\log \lambda_n(K) \sim -n\pi[\mathbf{K}(\operatorname{sech} \pi/\alpha)/\mathbf{K}(\tanh \pi/\alpha)]$, where $\mathbf{K}$ is the complete elliptic integral of the first kind, $\mathbf{K}(r) = \int_0^{\pi/2} (1 - r^2 \sin^2\theta)^{-1/2}\,d\theta$. Theorem III: If $\Gamma(\xi)$ is convex for large ξ and $\Gamma(\xi)/\xi \to \infty$, then $\log \lambda_n(K) \sim -\Gamma(\sigma_n)$, where σ_n is the unique solution of the equation $\Gamma(\sigma) = 2n \log(n/\sigma)$ $(0 < \sigma < n)$. Corollaries: If $\log \Gamma(\xi) \sim \alpha \log \xi$ $(\alpha > 1)$, then $\log \lambda_n(K) \sim -(2 - 2/\alpha)n \log n$; If $\log \Gamma(\xi)/\log \xi \to \infty$, then $\log \lambda_n(K) \sim -2n \log n$; If there happens to be a function k belonging to $L_p(-\infty, \infty)$ $(1 \leq p \leq 2)$ whose Fourier transform is K, then $T(K)$ is the integral operator on $L_2(-1, 1)$ with kernel $k(x-y)$, and the $\lambda_n(K)$ are the eigenvalues of the equation

$$\int_{-1}^{1} k(x-y)f(y)\,dy = \lambda f(x).$$

On the numerical solution of a class of non-linear integral equations of dispersion type. (Bulgarian. Russian and English summaries)

Bălgar. Akad. Nauk. Otd. Mat. Fiz. Nauk. Izv. Fiz. Inst. s Aneb **12** (1964), 143–151.

Authors' summary: "A method is presented in this work for a direct solution of non-linear singular integral equation systems of the type of the equation of F. E. Low and G. F. Chew, Castilejo, Dalitz and Dyson, G. F. Chew and S. Mandelstam, et al. The solution is obtained by the method of successive approximations, taking special measures to remove the instability of the iteration process. Resonance and adiabatic solutions are obtained for the Chew and Low equation. The adiabatic solution found in this work ceases to be analytic when the meaning of the link's constant is $f^2 = 0{,}07$."

On the completeness of a system of characteristic and adjoint elements of operators which are rational functions of a parameter. (Russian)

Dokl. Akad. Nauk SSSR **159** (1964), 951–954.

The problem is to determine whether a Hilbert space is the closed span of finite-dimensional invariant subspaces for a given completely continuous operator. The operators L considered are of the form $L = A + \sum_{i=1}^{n-1} \lambda^i A_i H^i + \lambda^n H^n$, where $A, A_1, \cdots, A_{n-1}$ are completely continuous operators, λ is a complex parameter, and H is a completely continuous, selfadjoint operator which has a sum of pth powers of its roots finite. The paper is of interest for the estimates of resolvents of such operators, from which the completeness results follow in a routine way.

Edwards, D. A. 6274

On the homeomorphic affine embedding of a locally compact cone into a Banach dual space endowed with the vague topology.

Proc. London Math. Soc. (3) **14** (1964), 399–414.

The author constructs a norm on a real, locally convex, separated linear space generated by a locally compact cone. With respect to this norm, the space is a Banach space which is shown to possess numerous interesting properties. For example, it is shown that the cone can be embedded homeomorphically into the Banach space with the w^*-topology. A result of Schaeffer concerning the existence of eigenvalues for certain positive operators is proved using the construction and a theorem of Bonsall.

S. Goldberg (College Park, Md.)

Ellis, A. J. 6275

The duality of partially ordered normed linear spaces.

J. London Math. Soc. **39** (1964), 730–744.

As a sequel to a paper of Edwards [#6274], the author considers a real partially ordered vector space X with a locally convex topology τ and with an order unit e such that $[0, e]$ is τ-compact. It is proved that X has an order unit norm which makes it the dual space of the Banach space of all linear functionals on X which are τ-continuous on norm bounded sets. A result is given dual to the theorem of Grosberg and Krein which links generating and normal cones in dual Banach spaces. The last section of the paper considers when the annihilator of an order ideal in a partially ordered vector space with an order unit intersects the base in the order dual space in an extremal set. This generalizes a theorem of Bonsall.

S. Goldberg (College Park, Md.)

Gähler, Siegfried 6276

Lineare 2-normierte Räume.

Math. Nachr. **28** (1964), 1–43.

In a previous paper [same Nachr. **26** (1963), 115–148; MR **28** #5423] the author investigated the notion of a 2-metric, a real-valued function of point-triples on a set X, whose abstract properties were suggested by the area function for a triangle determined by a triple in euclidean space; associated with a given 2-metric was a natural topology. The author showed that a metric space has a topologically equivalent 2-metric, but gave an example of a 2-metric space which is not metrizable.

In his present paper the author studies a related concept in the category of linear spaces. If L is a linear space, a real function on $L \times L$ is called a 2-norm if (1) $\|a, b\| = 0$ exactly when the vectors a and b are linearly dependent; (2) $\|a, b\| = \|b, a\|$; (3) for each real number r, $\|a, rb\| = r\|a, b\|$; (4) $\|a, b+c\| \leq \|a, b\| + \|a, c\|$.

Here are some of the main results of the paper. Theorem 2: A linear space L of dimension greater than 1 with a 2-norm $\|a, b\|$ has a 2-metric $\sigma(a, b, c) = \|b-a, c-a\|$. Theorem 4: A linear 2-normed space L is a locally convex topological vector space.

On the other hand, the author gives an example of a 2-normed vector space of uncountable dimension which is not metrizable and hence does not have any norm.

Hasumi, Morisuke; Seever, G. L. 6277

The extension and the lifting properties of Banach spaces.

Proc. Amer. Math. Soc. **15** (1964), 773–775.

A Banach space is said to have the extension property if for any Banach space F and any bounded linear map A from a subspace of F into E, there exists a linear extension A_e of A mapping all of F into E with $\|A_e\| = \|A\|$. E has the lifting property if for any closed subspace M of F, the space of bounded linear operators $[E, F]$ can be mapped onto the space of bounded linear operators $[E, F/M]$ under the map $\phi: T \to \eta T$, where η is the natural map from F onto F/M and $\|\phi\| = 1$. If E has the lifting property, then it is known that the conjugate space E' has the extension property. The authors prove that if E has the extension property, then E' has the lifting property if and only if E is finite-dimensional. *S. Goldberg* (College Park, Md.)

Cohen, Henry B. 6278

The k-norm extension property for Banach spaces.

Proc. Amer. Math. Soc. **15** (1964), 797–802.

Let k denote an infinite cardinal number. A k-family [set] is a family [set] whose cardinal number does not exceed k. If B is a set and C a family of subsets of B, C is said to have the binary intersection property [k-binary intersection property] if any non-empty subfamily [k-subfamily] of C whose members meet pairwise has a non-empty intersection. A normed linear space B is called k-separable if B has a dense k-subset. B has the norm extension property [k-norm extension property] if every bounded linear operator mapping a subspace of a normed linear space Y [k-separable normed linear space Y] can be extended to a linear operator, with the same norm, defined on all of Y. The author proves the following theorem. The following statements are equivalent for a real normed linear space B. (i) B has the k-norm extension property. (ii) If M is a k-separable subspace of B and Y is a normed linear space of the form $M \oplus \{x\}$, there is a linear operator $H: Y \to B$ of norm 1 such that H is the identity on M. (iii) The family of closed spheres of B has the k-binary intersection property. The theorem was proved by Nachbin [Trans. Amer. Math. Soc. 68 (1950), 28–46; MR 11, 369] with norm and binary replacing k-norm and k-binary, respectively, and $M = B$ in (i), (ii) and (iii). The Banach space $C^*(S)$ of bounded continuous functions on a topological space S is shown to have the k-norm extension property under certain conditions. For example, the compact Hausdorff spaces for which $C^*(S)$ has the k-norm extension property are characterized.

Correction to "The existence of invariant subspaces".

Bull. Amer. Math. Soc. 71 (1965), 396.

From the authors' correction: "The proof of the existence of invariant subspaces announced in this Bulletin 70 (1964), 718–721 [MR 28 #4329] is false. We now withdraw the announcement and make no statement either for or against the existence of invariant subspaces."

Karamata, J. 6280

Contribution à une théorie générale de la croissance des fonctions.

Bull. Acad. Serbe Sci. Arts Cl. Sci. Math. Natur. Sci. Math. 31 (1963), no. 4, 29–30.

Let $(A, <)$ be a directed set (in the sense of Moore-Smith limits), and consider the class Φ of functions f defined on A, with values in a Banach space F. A partial ordering of Φ is defined as follows. Let f and g be functions in Φ, and write $f \prec g$ in case there exists a scalar λ such that for every $\varepsilon > 0$ there exists an x_ε such that $\|f(x) - \lambda g(x)\| \leq \varepsilon g(x)$ whenever $x_\varepsilon < x$. The author fails to note that when $f \prec g$ with $\lambda \neq 0$, then $g \prec f$, and when $f \prec g$ with $\lambda = 0$, then $g \prec f$ is false unless g is eventually zero. A number of remarks concerning partially ordered sets are adjoined.

Lozanovskiĭ, G. Ja. 6281

On topologically reflexive KB-spaces. (Russian)

Dokl. Akad. Nauk SSSR 158 (1964), 516–519.

Soit X un KB-espace, c'est-à-dire un espace linéaire réticulé complet, muni d'une norme satisfaisant les propriétés: $|x| \leq |y|$ entraîne $\|x\| \leq \|y\|$, $x_n \downarrow 0$ entraîne $\|x_n\| \to 0$, $0 \leq x_n \uparrow +\infty$ entraîne $\|x_n\| \to +\infty$.

L'auteur construit des sous espaces de X qui sont de KB-espaces réflexifs, et qui sont des espaces analogues au espaces L^p $(p > 1)$, ou aux espaces réflexifs de Orlicz.

Si X est un KB-espace à unité, alors pour chaque $x \in X$ il existe un sous espace linéaire E, normal (c'est-à-dire $|x| \leq |y|$ et $y \in E$ entraîne $x \in E$), et total (c'est-à-dire $x \perp E$ entraîne $x = 0$), qui contient x, et qui est un KB espace réflexif par rapport à une certaine nouvelle norme.

Si X est un espace linéaire réticulé complet quelconque, alors l'ensemble de tous les sous espaces linéaires, normaux et totals, qui sont des KB-espaces réflexifs, est un treillis distributif par rapport à l'inclusion.

Mel'cer, M. M. 628

Weakly completely continuous spectra of locally conve spaces. (Russian)

Dokl. Akad. Nauk SSSR 157 (1964), 265–267.

The author announces without proof a number of resul about certain kinds of projective and inductive limits locally convex spaces. Let $\{E_\alpha, \pi_\alpha^\beta\}$ be an inverse spectr family of locally convex spaces E_α and continuous line maps $\pi_\alpha^\beta: E_\beta \to E_\alpha$, and let E be the projective limit. locally convex space E is said to be a W-space if it is th projective limit of $\{E_\alpha, \pi_\alpha^\beta\}$, where for each α there is $\beta > \alpha$ such that for each 0-neighborhood U in E_β the $\pi_\alpha^\beta(U)$ has weakly compact closure in E_α. Among oth things it is asserted that a W-space is complete and sem reflexive and that every W-space is the limit of a fami of Banach spaces. Moreover, closed subspaces of a space, quotient spaces, products, projective limits, a inductive limits of a sequence of W-spaces are also spaces if they are complete and Hausdorff. The author al considers inductive limits, where the maps $\pi_\beta^\alpha: E_\alpha \to$ are weakly completely continuous. This work extends th of D. A. Raĭkov [same Dokl. 113 (1957), 984–986; MR 754].

R. G. Bartle (Urbana, I

Pisanelli, Domingos 62

Sull'invertibilità degli operatori analitici negli spazi Banach.

Boll. Un. Mat. Ital. (3) 19 (1964), 110–113.

Let f be a function whose domain is an open subset o Banach space X and whose image space is a Banach spa Y. Suppose that, inside some open ball with center x_0 is analytic in the sense of Fréchet. [For definitions, see Hille, *Functional analysis and semi-groups*, Amer. Ma Soc., New York, 1948; MR 9, 594.] Then the followi theorem holds. If the Fréchet differential $\delta f(x_0, h)$ is a o one map from X onto Y, then there exists a uniq inverse analytic map g whose domain is an open ball in with centre y_0, where $y_0 = f(x_0)$. This theorem is a gener ization of the well-known theorem for Euclidian spaces invertibility of differentiable transformations with n vanishing Jacobian. The author leaves as an open questi the possibility of extending the above theorem to analy maps between locally convex spaces.

G. G. Gould (Syracuse, N.

Roelcke, W. 6

Über die Hebbarkeit der Unstetigkeiten gewisser Abl dungen topologischer Räume in Banach-Räume.

Math. Z. 79 (1962), 158–179.

Let X be a topological space and B a Banach space with conjugate space B^*. Let Ω be a family of subsets of X having empty interiors, such that if $N_k \in \Omega$ $(k=1, 2, \cdots)$, then $\bigcup N_k \in \Omega$, and such that if $M \subseteq N$ and $N \in \Omega$, then $M \in \Omega$. Let $p: X \to B^*$ be a mapping with the following property (here p_x is the image under p of $x \in X$): For all $u \in B$ there exists a complex-valued continuous function S_u on X such that the relation $p_x u = S_u(x)$ holds for all x except on some set $N_u \in \Omega$. The author seeks conditions that the discontinuities relative to the topology $\sigma(B^*, B)$ be "removable" in the following sense, namely, that there exist an "alteration" $q: X \to B^*$ of p such that q is (everywhere) continuous relative to $\sigma(B^*, B)$ and such that $q_x = p_x$ for all x except on some set in Ω.

The discontinuities of p are not in general removable, but are removable in several cases; for example, if X is locally compact, the discontinuities of p are removable.

S. Heckscher (Swarthmore, Pa.)

Gribanov, Ju. I. 6285

On the theory of the reduction method for infinite systems of linear equations. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 5 (42), 12–16.

A Banach space l of infinite sequences $X = (x_1, x_2, \cdots)$ is called a sequence space if (1) l contains the set h of all finitely non-zero sequences; (2) $\|X\| = 0$ implies $X = \{0\}$; (3) $\|X\| = \sup \|P_n X\|$, where P_n is the projection to the first n coordinates. Consider a system of linear equations (I) $X = AX + H$ in a sequence space l where A is a matrix operator in l with norm $\|A\| < 1$ and $X, H \in l$, and corresponding reduced systems $X_n = P_n A P_n X_n + P_n H$, $n = 1, 2, \cdots$. The assumptions on l and A imply the existence and the uniqueness of the solutions of these systems. The author says that the reduction method is norm-convergent in l to the solution of the system (I) if the sequence $\{X_n\}$ converges to X in l. Theorem 4: The reduction method is norm-convergent in l to the solution of the system (I) if and only if $X \in [l]$, where $[l]$ denotes the closure of h in l. In this case, (II) $\|X - X_n\| \leq \|X - P_n X\|(1 - \|A\|)^{-1}$. As a consequence, the reduction method is always norm-convergent for any sequence space l satisfying $l = [l]$ (e.g., $l = l_p$, $p \geq 1$). For $l = m$, the reduction method is norm-convergent if $A(m) \subseteq c_0$ and $H \in c_0$, because $[m] = c_0$. The sequence spaces considered here are more special and the restriction on A is much weaker than those studied earlier by the author [same Izv. **1962**, no. 1 (26), 28–40; MR **25** #1458]. The estimate (II) for approximation is less effective than those obtained in the previous paper because of the weaker assumption on A.

M. Hasumi (Mito)

Bahtin, I. A. 6286

On the existence of eigenvectors of positive linear operators which are not completely continuous. (Russian)

Mat. Sb. (*N.S.*) **64 (106)** (1964), 102–114.

The principal theorem proved here is this. Let A be a linear operator acting on a partially ordered Banach space. Suppose there exists a non-negative vector u_0 having the property that for each non-negative x there exist $\alpha, \beta > 0$ such that $\alpha u_0 \leq Ax \leq \beta u_0$ (A is said to be u_0-bounded), and suppose (*) that $\beta/\alpha \leq k$ for a fixed number k. Then A has a non-negative eigenvector. Furthermore, if every bounded monotonic sequence of vectors converges then condition (*) is unnecessary.

This generalizes a great many theorems, the oldest of which is O. Perron's classical statement [Math. Ann. **64** (1907), 1–76] that every non-singular matrix with non-negative elements has a non-negative eigenvector.

G. Hufford (Boulder, Colo.)

Orlicz, W. 6287

A note on modular spaces. VII.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 305–309.

Let ρ be a modular on a vector lattice X in which every bounded countable subset has a least upper bound. If one defines a metric on X by $d(x, y) = \inf\{\varepsilon \mid \rho[(x-y)/\varepsilon] \leq \varepsilon\}$, X has been shown by J. Musielak and W. Orlicz [Studia Math. **18** (1959), 49–65; MR **21** #298] to have all the properties of an F-space, in the sense of Banach [*Théorie des opérations linéaires*, Monogr. Mat., Tom 1, Warsaw, 1932], except possibly completeness. The present paper considers the hypothesis: If $x_1, x_2, \cdots \geq 0$ and $\sum \rho(x_n) < \infty$, then $\bigvee x_n$ exists. With this hypothesis, X is shown actually to be an F-space for the above metric. Furthermore, if we denote $d(x, 0)$ by $\|x\|$, the following theorem holds: Whenever $\|x_1\| + \|x_2\| + \cdots < \infty$, then $y = \bigvee_n(|x_1| + \cdots + |x_n|)$ exists, $z = \bigvee x_n$ exists, $\|y\| \leq \sum \|x_n\|$ and $\rho(z) \leq \sum \rho(x_n)$. The last section considers mappings from a suitable subset of X to another vector lattice. (The earlier papers in this series may be traced by starting with Part VI [Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **11** (1963), 449–454; MR **28** #3316].)

H. Gordon (Philadelphia, Pa.)

Riedl, John 6288

Partially ordered locally convex vector spaces and extensions of positive continuous linear mappings.

Math. Ann. **157** (1964), 95–124.

The author generalizes to locally convex [or normed] partially ordered vector spaces the extension theorems and properties of locally convex [or normed] vector spaces, and establishes results that correspond to the known ones. The article also contains results about normal cones; about representation of spaces into, or onto, $C(X)$, about isomorphisms of spaces in terms of the lattice of closed linear subspaces and the incidence relation with the positive cone, and about isomorphisms of spaces in terms of the preordered semigroup of continuous linear operators.

L. Nachbin (Rochester, N.Y.)

Vekaler, A. I. 6289

The operations of partial multiplication in vector lattices. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 759–762.

Wie es bekannt ist [vgl. z.B. B. Z. Vulih, *Introduction to the theory of partially ordered spaces* (Russian), Chapter V, Fizmatgiz, Moscow, 1961; MR **24** #A3494], gibt es zu jedem Archimedischen Vektorverband X einen extremalen bikompakten Raum P so, dass X zu einer Menge von stetigen Funktionen auf P isomorph ist, wobei angenommen wird, dass jede von diesen Funktionen auch die Werte $\pm\infty$ auf einer nirgends dichten Teilmenge von P erreichen darf. Die Multiplikation dieser Funktionen kann mit Hilfe des Isomorphismus in die Menge X übertragen

werden; so entsteht in X eine Multiplikation, welche im allgemeinen nicht zu jedem geordneten Paar von Elementen ein Produkt zuordnet. Diese Multiplikation heisst Darstellungsmultiplikation; sie erfüllt gewisse Axiome.

Es sei in X eine Multiplikation gegeben, welche die obenangeführten Axiome erfüllt. Der Verfasser gibt Bedingungen an, unter welchen diese Multiplikation mit einer Darstellungsmultiplikation identisch ist. Dies geschieht z.B. unter Voraussetzung, dass das Produkt für je zwei Elemente von X definiert ist. Eine Darstellungsmultiplikation in einem bedingt vollständigen Vektorverband X erklärt die Ordnung in X in gewissem Sinne eindeutig. *M. Novotný* (Brno)

Girardeau, Jean-Pierre 6290

Propriétés d'interpolation des espaces de Hilbert.

C. R. Acad. Sci. Paris **258** (1964), 44–46.

Let $(E_i, F_i)_{i=1,2}$ be two pairs of Banach spaces such that $F_i \subset E_i$, where this injection is continuous. Two Banach spaces H_1, H_2 such that $F_i \subset H_i \subset E_i$ (all injections being continuous) are said to have the property of interpolation if every continuous linear mapping of E_1 into E_2 whose restriction is continuous from F_1 to F_2 is also a continuous mapping from H_1 to H_2. In this paper the author gives certain conditions on the spaces (E_i, F_i) in order that the property of interpolation be valid. For example, he assumes the existence of a linear mapping $L_i : E_i' \to F_i$ with the following properties: $L_i(E_i') = F_i$ (algebraically) and $\langle z, u \rangle \geq 0$, where $z = L_i(u)$. The definition $(x \mid y)_i = \langle x, u \rangle$ for $y = L_i(u)$ yields a non-degenerate, positive, hermitian form on F_i. The completion of F_i with respect to this form is a Hilbert space H_i such that $H_i \subset E_i$, this injection is continuous, and F_i is dense in H_i [cf. L. Schwartz, Séminaire Bourbaki, 1961/62, deuxième édition, Fasc. 3, Exposé 238, Secrétariat mathématique, Paris, 1962; MR **28** #3561]. Under these conditions the author proves that the spaces H_1 and H_2 have the property of interpolation. As a corollary he derives a recent result of J.-L. Lions and J. Peetre [Inst. Hautes Études Sci. Publ. Math. No. 19 (1964), 5–68; MR **29** #2627]. *G. Maltese* (College Park, Md.)

Golovkin, K. K. 6291

The ε-entropy of certain compact sets of differentiable functions in spaces with monotone norm. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 261–263.

Let $C^\infty(\Omega)$ be the space of all infinitely differentiable functions on an n-dimensional hypercube Ω. Let $\|\cdot\|$ be a monotone norm on $C^\infty(\Omega)$ which is invariant under translation, and denote by H the closure of the family $\{u \in C^\infty(\Omega) : \|u\| < \infty\}$. Having defined two norms $\|\cdot\|_k$ $(k = 1, 2)$ of type L_p [respectively, C], the author obtains a lower [upper] estimate for the ε-entropy of the sets $\{u \in H : \|u\| + \|u\|_k \leq M\}$; these are the "compact sets" in the title of this article. *G. L. Krabbe* (Lafayette, Ind.)

Hunt, Richard A. 6292

An extension of the Marcinkiewicz interpolation theorem to Lorentz spaces.

Bull. Amer. Math. Soc. **70** (1964), 803–807.

This note contains an extension of Marcinkiewicz's interpolation theorem to spaces of Lorentz type. If f is a measurable function on some measure space, denote by $f^*(t)$ its decreasing rearrangement on the real half-line $0 < t < \infty$. Set

$$\|f\|_{pq} = \left(\int_0^\infty (t^{1/p} f^*(t))^q \frac{dt}{t}\right)^{1/q}, \qquad 0 < p < \infty,\ 0 < q < \infty,$$

$$= \sup_{0<t<\infty} t^{1/p} f^*(t), \qquad 0 < p \leq \infty,\ q = \infty.$$

(This is not a norm in general.) Theorem: If T is a quasi-linear operator, $|T(f+g)| \leq K(|Tf| + |Tg|)$, such that

$$\|Tf\|_{p_i' q_i'} \leq B_i \|f\|_{p_i q_i}, \qquad i = 0, 1,\ p_0 < p_1,\ p_0' \neq p_1',$$

then

$$\|Tf\|_{p_\theta' q} \leq B_\theta \|f\|_{p_\theta q}$$

for $0 < \theta < 1$, $1/p_\theta = (1-\theta)/p_0 + \theta/p_1$, $1/p_\theta' = (1-\theta)/p_0' + \theta/p_1'$. The proof, which depends on Hardy's inequality, is short and elegant. (For previous work in the same direction, see Krein and Semenov [Dokl. Akad. Nauk SSSR **138** (1961), 763–766; MR **25** #4352], Calderón [Studia Math. (Ser. On the continuity of lattice automorphisms on continuous function lattices.

Illinois J. Math. **8** (1964), 419–424.

Let $C(E)$ denote the lattice of all real-valued continuous functions on a compact Hausdorff space E. In general, lattice automorphisms are not continuous in the topology of uniform convergence. The author considers the following possibilities. Property (K): all lattice automorphisms of $C(E)$ are continuous; (K_0): all compact subspaces of E have property (K); (K_1): a lattice automorphism of $C(E)$ is continuous if and only if its inverse is continuous. Theorem 1: E has property (K_1) if and only if it is not the Stone-Čech compactification of any proper dense co-zero set. Theorem 2: E has property (K_0) if and only if it does not contain a copy of βN. The methods of proof follow those of Kaplansky [Amer. J. Math. **70** (1948), 626–634; MR **10**, 127]. *L. Gillman* (Rochester, N.Y.)

Jamison, Benton 6295

Asymptotic behavior of successive iterates of continuous functions under a Markov operator.

J. Math. Anal. Appl. **9** (1964), 203–214.

Let S be a compact metric state space and $P(x, E)$ a transition probability operator on S. It is assumed that the operator $Tf = \int_S f(y)P(\cdot, dy)$ maps the Banach space $C(S)$ of all complex-valued continuous functions under sup norm into itself. In this paper the asymptotic behavior of the sequence $\{T^n f\}$ is studied. T is called uniformly stable if the sequence $\{T^n f\}$ is equicontinuous for each $f \in C(S)$. It is called uniformly stable in the mean if in the above definition $\{T^n f\}$ is replaced by $\{(1/n) \sum_{k=1}^{n} T^k f\}$. Under the hypotheses of uniform mean stability the author shows that $\{(1/n) \sum_{k=1}^{n} T^k f\}$ converges uniformly to a constant if and only if there are not two disjoint nonvoid topologically and stochastically closed subsets in S. Furthermore, under the stronger assumption of uniform stability, several conditions are given which are necessary and sufficient for the uniform convergence of $\{T^n f\}$ to constants. Two applications of these results are made: one concerns convolutions of measures on compact separable groups, and the other a certain random mapping problem.

The order dual of the space of Radon measures.

Trans. Amer. Math. Soc. **113** (1964), 219–239.

The author continues the study of the first and second duals of the space of continuous functions that was initiated by S. Kaplan [same Trans. **86** (1957), 70–90; MR **19**, 868; ibid. **93** (1959), 329–350; MR **22** #2888; ibid. **101** (1961), 34–51; MR **24** #A1598]. (The last paper will be referred to as III.)

This paper is concerned with the spaces L_k, L_b, and $\bigcup L(K)$ of measures on a locally compact space X that are Radon measures, that are finite, and that have compact support, respectively, and their order duals M_k, M_b, and M. Various relations among these spaces are studied, and among other things, it is shown that M_k and M_b appear as ideals in M, and that C (the set of all continuous real-valued functions on X) can be embedded in M.

The author further considers two questions raised in III by S. Kaplan: (1) if every atomic (Radon) measure on a space is finite, does it follow that every measure on the space is finite; and (2) for each $f \in M_k$ does there exist $g \in M_k$ so that the closed ideal generated by f is dominated by some multiple of g. Both questions are answered in the negative by exhibiting a locally compact space T for which each fails. The space is obtained using the following theorem. Let μ be a Radon measure on the σ-compact space X. Then there exists a countably compact space T containing X as a topological subspace, and a Radon measure v on T so that the restriction of v to X is μ if and only if the atomic part of μ (considered as a function on X) vanishes at infinity.

Convex functions of several variables and vector-valued Orlicz spaces.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **11** (1963), 279–284.

A function of n variables $M(\mathbf{u})$, $\mathbf{u}=(u_1,\cdots,u_n)$, $u_1,\cdots,u_n\geq 0$, is said to be convex if for $a,b\geq 0$, $a+b=1$, $M(a\mathbf{u}_1+b\mathbf{u}_2)\leq aM(\mathbf{u}_1)+bM(\mathbf{u}_2)$. $M(\mathbf{u})$ is called non-decreasing if it is non-decreasing in each variable separately. The complement to a non-decreasing, convex $M(\mathbf{u})$ with $M(\mathbf{0})=0$ is given by

$$N(\mathbf{v}) = \sup_{\mathbf{u}\geq 0}\left[\sum_{i=0}^{n} u_i v_i - M(\mathbf{u})\right].$$

It is shown that if $N(\mathbf{v})$ is the complement of $M(\mathbf{u})$, then $M(\mathbf{u})$ is the complement of $N(\mathbf{v})$. (The statement and proof of this theorem are marred by the fact that the author fails to make the observation that a convex $M(\mathbf{u})$ is always expressible as the integral of a non-decreasing system.)

By means of a non-decreasing convex function $M(\mathbf{u})$ of n variables, a vector-valued Orlicz space may be defined, but this turns out to be merely the direct sum of n Orlicz spaces.
R. O'Neil (Houston, Tex.)

Rosenblatt, M. 6302

Almost periodic transition operators acting on the continuous functions on a compact space.

J. Math. Mech. **13** (1964), 837–847.

For a compact Hausdorff space X let T be a non-negative linear operator on $C(X)$ with $T1=1$. The author is concerned with consequences of the assumption that $\{T^n: n\geq 1\}$ be almost periodic on $C(X)$ in the sense that $\{T^n f, n\geq 1\}$ is conditionally compact, $f\in C(X)$.

From results of de Leeuw and the reviewer [Acta Math. **105** (1961), 63–97; MR **24** #A1632] one knows that $C(X)=C_0\oplus C_p$, where C_0 [respectively, C_p] is the closed invariant subspace of all f with $\|T^n f\|\to 0$ [spanned by eigenvectors of T corresponding to eigenvalues of unit modulus]; the corresponding projection of $C(X)$ onto C_p is provided by E, the identity of the least ideal K of the compact semigroup formed by the strong operator closure of $S=\{T^n: n\geq 1\}$. Call T irreducible if for any f in $C(X)$ and x in X, $T^n f(x)>0$ for some n. From an earlier result of the author [Teor. Verojatnost. i Primenen. **9** (1964), 205–222; MR **29** #1540] one then has C_p an algebra. This leads to the author's first theorem, which, roughly stated, asserts that if T is irreducible, then C_p is the algebra of all continuous functions on a quotient space X' of X, and $T|C_p$ is induced by a self-homeomorphism of X'.

K (above) is a compact topological group, and the author uses harmonic analysis on K (Theorem 2) to obtain an integral representation of $\lim_{n\to\infty}(1/n)\sum_1^n\lambda^{-j}T^j$, where λ is any eigenvalue of unit modulus.

Finally, when T is irreducible, there is a unique probability measure on X fixed under T^*; for the corresponding L^2 space the natural extension of T acts as an isometry on the closure of C_p and as a dissipative operator on the (orthogonal) closure of C_0. Extensions to other positive operators are given.

{The author's assertion (Lemma 2) that C_p is an algebra is false. Let $X=\{z\in\mathbf{C}: |z|=0,1\}$, $Tf(z)=f(z)$, $z\neq 0$, $Tf(0)=(1/2\pi)\int f(e^{i\theta})\,d\theta$. Then $T^2=T$ is a projection (thus $=E$) whose self-adjoint and separating range $EC(X)=C_p$ cannot be an algebra since $C_p\neq C(X)$. What can be proved is that $C_p|Y$ is an algebra, where Y, the "support of E", is the closure of the union of the supports of the measures $E(x,\cdot)$, where $Ef(x)=\int f(y)E(x,dy)$; one need only note that $C_p|Y$ is closed in $C(Y)$ and apply the argument of the author's earlier paper that the real elements of $C_p|Y$ form a lattice, hence a subalgebra of $C^R(Y)$ by Stone's proof of the Stone-Weierstrass theorem. When T is irreducible, $X=Y$, so that none of the results of this paper are invalidated.}

Problèmes aux conditions initiales, dans la théorie des distributions.

Univ. Lisboa Revista Fac. Ci. A (2) **10** (1963), 91–130.

Im Anschluß an Sebastião e Silvas axiomatische Einführung der Distributionen [dieselben Revista (2) **4** (1955), 79–186; corrigenda (2) **5** (1956), 169–170; MR **17**, 766] werden Anfangsaufgaben für lineare inhomogene Systeme von gewöhnlichen Differentialgleichungen untersucht. Seien $u=u(t)$, $f=f(t)$ vektorielle Distributionen, $A=A(t)$ eine quadratische Matrix. Untersucht wird das System $u'=Au+f$. Es wird gezeigt, daß jede Distribution u, welche in einem Intervall Lösung des Systems ist, sich eindeutig als Lösung für alle t fortsetzen läßt, falls $A(t)$ eine differenzierbare Funktion ist. Ist A von der Klasse C^p und f von der Ordnung höchstens $p+1$ und haben die Stammfunktionen Grenzwerte für $t\to a-0$, so ist die Anfangswertaufgabe für beliebige Vorgaben von $u(a-0)$ eindeutig durch eine Distribution $u(a-0)$ lösbar. Für den Wert einer Distribution werden dabei die üblichen Definitionen verwendet. Ist A unendlich oft differenzierbar, so ist die Anfangswertaufgabe für $a-0$ dann und nur dann für alle t eindeutig lösbar, wenn f eine Distribution ist, die eine Stammfunktion besitzt, welche einen Grenzwert für $t\to a-0$ hat. Es folgen Anwendungen auf Differentialgleichungen höherer Ordnung mit konstanten Koeffizienten und auf Systeme mit konstanten Koeffizienten, wobei Heaviside-Funktionen als Störfunktionen besondere Beachtung finden.

On the duality of certain Hilbert spaces of tempered distributions.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 293–297.

For $f \in \mathscr{S}$ (the space of rapidly decreasing functions on N-dimensional Euclidean space E^N) the norms

$$\|f\|_{0,q} = \left(\int (1+|x|^2)^q |f(x)|^2\,dx\right)^{1/2},$$

$$\|f\|_{m,q} = \left(\sum_{|\alpha|\leq m} \|D^\alpha f\|_{0,q}^2\right)^{1/2},$$

where q is real and m is a non-negative integer, and

$$\|f\|_{-m,-q} = \sup\{|(\phi, f)| : \phi \in \mathscr{S} \text{ and } \|\phi\|_{m,q} = 1\}$$

are introduced. The completion of $\mathscr{S}$ in the norm $\|\cdot\|_{m,q}$, m an integer, q real, is denoted by $G_{p,q}$. A number of results are proved which are analogous to those usually proved for the spaces H^m. In particular, it is shown that the map $f \to (\cdot, f)$ maps $\bigcup_{p,q} G_{p,q}$ onto $\mathscr{S}'$. Some estimates involving these norms are also given, for example, an analogue of Ehrling's estimate.

Martineau, André 6306

Sur une propriété universelle de l'espace des distributions de M. Schwartz.

C. R. Acad. Sci. Paris **259** (1964), 3162–3164.

Author's summary: "La plupart des espaces nucléaires de l'analyse sont plongeables comme sous-espaces de $\mathscr{D}'$ ou d'un espace $\mathscr{D}'^N$, N étant un cardinal inférieur ou égal à $2^{\aleph_0}$."

A space E (presumably separated and locally convex) is termed s-nuclear if, for each convex balanced neighbourhood U of 0 in E, there exists a convex balanced neighbourhood V of 0 in E such that the natural map of E_V into E_U is expressible in the form $v \circ u$, where $v: E_V \to s$ and $u: s \to E_U$ are continuous, s being the space of rapidly decreasing sequences. (The terminology and notations are those of A. Grothendieck [Mem. Amer. Math. Soc. No. 16 (1955), see especially Chapter II, p. 60 et seq.; MR 17, 763].) The author announces some universal properties of $\mathscr{D}'$ (the space of distributions on the line). For example: the class of s-nuclear spaces is identical with the class of subspaces of $\mathscr{D}'^N$, and with the class of subspaces of s'^N (s' the space of slowly increasing sequences); the s-nuclear Fréchet spaces are exactly the Fréchet subspaces of $\mathscr{D}'$. Several standard spaces of real- and complex-analytic functions are stated to be subspaces of $\mathscr{D}'$. The subspaces of $\mathscr{D}'$ and those of $s'^{\aleph_0}$ form identical categories. Dual results: $\mathscr{E}(V)$ (the space of indefinitely differentiable functions on a σ-compact C^∞ manifold V) and $H(V)$ (the space of holomorphic functions on a Stein manifold V, or an open submanifold V of C^n) are each quotient spaces of s.

On Rellich's theorem concerning infinitely narrow tubes.

Canad. Math. Bull. **7** (1964), 435–440.

This brief paper contains a proof of a theorem of Rellich which states that the Laplacian operator with zero boundary conditions associated with a domain G has discrete spectrum if C is an "infinitely narrow tube". An infinitely narrow tube with a straight line l as axis is a set which is contained in some half-space and whose intersection with a solid cylinder of any positive radius about l contains all but a bounded part of the set. The proof makes use of a variational principle which is first applied to the corresponding operator associated [...] bounded subset of G, then to that associated w[...] unbounded remainder of G, and finally to the [...] operator.

Theorem 1: Let A be a linear operator (of a typ[...] specified shortly) that is symmetrized by a strictly p[...] operator H, and let P be a real polynomial. S[...] $P(A) \neq P(0) \cdot$ iden. Then a necessary and su[...] condition that A possess (necessarily real) eigenv[...] satisfying both $P(\lambda) \leq 0$ and $P(\lambda) \geq 0$ is that ther[...] $f_0 \neq 0$ such that $(HP(A)f_0, f_0) = 0$. If, in addition, P[...] 0, then there exist eigenvalues satisfying both P[...] and $P(\lambda) > 0$.

The present note is based upon the author's earlier work [Uspehi Mat. Nauk 12 (1957), no. 4 (76), 201–207; MR 19, 873] and consequently employs, as the central hypothesis, the direct assumption that A has spectrum consisting only of eigenvalues of finite multiplicity which accumulate only at zero. (Indeed, the only other hypotheses on A are that it should be defined on, and leave invariant, a dense linear manifold contained in the domain of H. Observe that this insures that $P(A)$ is defined on the same domain and is also symmetrized by H. The main point is to show that, in fact, $P(A)$ enjoys all the properties of A.)

Theorem 1 can be used to obtain separation theorems for the eigenvalues of A, e.g., if $\alpha \neq \beta$ are real numbers, then, using $P(\lambda) = (\lambda - \alpha)(\lambda - \beta)$, we obtain Theorem 2: If there exists a vector $f_0 \neq 0$ such that $(H(A^2 - (\alpha+\beta)A + \alpha\beta)f_0, f_0) = 0$, then there is an eigenvalue of A between α and β. Similarly, let $f_0 \neq 0$ and define

$$\gamma_0 = (Hf_0, f_0), \quad \gamma_1 = (HAf_0, f_0), \quad \gamma_2 = (HA^2 f_0, f_0).$$

Then, for any α, $\alpha\gamma_0 \neq \gamma_1$, there is at least one eigenvalue of A between α and $(\alpha\gamma_1 - \gamma_2)/(\alpha\gamma_0 - \gamma_1)$ (Theorem 3).

A. Brown (Ann Arbor, Mich.)

Kaniel, S. 6312

Unbounded normal operators in Hilbert space.

Trans. Amer. Math. Soc. **113** (1964), 488–511.

The author introduces a class of operators in Hilbert space, called unbounded normal operators, which are extensions of symmetric operators. These operators are defined as follows. Let T_0 have domain $D(T_0)$, a dense subspace of Hilbert space. Let its adjoint T_0^* be densely defined and let T_1^* be the restriction of T_0^* to a dense subspace. Form the adjoint $T_1 = T_1^{**} \supset T_0$. Define H_λ to be the kernel of $T_1 - \lambda I$ and H_λ^* to be the kernel of $T_0^* - \lambda I$. (T_0, T_1^*) forms a normal pair if (a) $f \in D(T_1^* T_0)$ implies $f \in D(T_0 T_1^*)$ and $T_1^* T_0 f = T_0 T_1^* f$; (b) The closure of $D(T_1^* T_0)$ with respect to the T_0 norm is $D(T_0)$; (c) $D(T_0^*) \cap H_\lambda$ is dense in H_λ and $D(T_1) \cap H_\lambda^*$ is dense in H_λ^*. The operator T_0 is called normal if T_0 has a mate T_1^* such that (T_0, T_1^*) forms a normal pair. T_0 is completely normal if it is normal and has a bounded inverse defined on the entire space and which is also normal. The author mentions that many operators like constant coefficient partial differential operators satisfy conditions (b) and (c). Properties of normal operators are then given. For example, the following theorem is proved. Theorem: Let (T_0, T_1^*) form a normal pair. Suppose T_1^* is regular in a region $\bar{D}$, i.e., $T_1^* - \lambda I$ has a bounded inverse for each λ in $\bar{D}$. If T_1^* has finite deficiency index, then there exists an analytic function $G(z, w) = w^n + h_1(z)w^{n-1} + \cdots + h_n(z)$, $z \in D$, such that for any z_0, the zeros of $G(z_0, w)$ are the eigenvalues of T_0^* restricted to H_{z_0}. An interesting example is given of a normal operator which is regular in the plane and which is not a polynomial in a symmetric operator. The next part of the paper gives conditions under which an operator has a normal extension and, in particular, a complete normal extension. Most of the theorems assume that T_0 and T_1^* are regular in the plane. The remaining portion of the paper deals with properties of the spectrum of normal extensions. In particular, the distribution of the eigenvalues of complete normal extensions is investigated.

A new application of the fixed-point principle in the theory of operators in a space with indefinite metric. (Russian)

Dokl. Akad. Nauk SSSR **154** (1964), 1023–1026.

Let P_+ be a projection on a Hilbert space $\mathscr{H}$, let $P_- = 1 - P_+$ and $J = P_+ - P_-$. The symmetry J defines an indefinite metric $[x, y] = (Jx, y)$. As is customary, we call an (invertible) operator U "J-unitary" if $U^*JU = J$ and a (densely defined) operator A "J-selfadjoint" if JH is selfadjoint. It was noted some time ago by the author [Uspehi Mat. Nauk **5** (1950), no. 2 (36), 180–190; MR **14**, 56] that the basic structure theorems for J-selfadjoint and J-unitary operators could be viewed as applications of fix-point theorems. (The original theorem in this connection goes back to Pontrjagin [Izv. Akad. Nauk SSSR Ser. Mat. 8 (1944), 243–280; MR **6**, 273]. The fix-point approach has been exploited by others, notably Iohvidov [Trudy Moskov. Mat. Obšč. **5** (1956), 367–432; MR 18, 320] and, more recently, Langer [Math. Ann. **152** (1963), 434–436; MR **28** #1492] and Fan [Bull. Amer. Math. Soc. **69** (1963), 773–777; MR **28** #1494].) In this note the Schauder-Tychonov fix-point theorem is used to prove the following. Let $\mathscr{P}_+$ denote the "positive set" $\{x : [x, x] \geq 0\}$ and let $\mathscr{M}_+$ denote the set of all maximal subspaces lying in $\mathscr{P}_+$. Let T be a bounded linear operator on $\mathscr{H}$ and suppose (1) $Tx \in \mathscr{P}_+$, $Tx \neq 0$ for all $x \in \mathscr{P}_+$, $x \neq 0$; (2) $\mathscr{P}_+ T \mathscr{P}_-$ is compact; and (3) for at least one $L_0 \in \mathscr{M}_+$ we have $T(L_0) \in \mathscr{M}_+$. Then (a) $T(\mathscr{M}_+) \subset \mathscr{M}_+$, and (b) for at least one $L_0 \in \mathscr{M}_+$ we have $T(L_0) = L_0$. This theorem is then used to deduce the appropriate spectral decomposition theorems for J-unitary and J-selfadjoint operators, the latter result subsuming a theorem recently announced by Langer [loc. cit.].

Krein, M. G.; Langer, G. K. [Langer, Heinz] 6315

On the theory of quadratic pencils of self-adjoint operators. (Russian)

Dokl. Akad. Nauk SSSR **154** (1964), 1258–1261.

A quadratic pencil of operators is a family of the form $L(\lambda) = \lambda^2 + \lambda B + C$, where B, C are operators. If $\lambda \neq 0$ and $L(\lambda)$ is invertible, then λ is a regular point; the irregular points constitute the spectrum of $L(\lambda)$. The present note is a brief report on a considerable body of theory concerning the spectral structure of such pencils, and this review will not attempt more than a hasty sampling of the stated results.

The minimal hypotheses on B and C are $B = B^*$ and C closed with $\mathscr{D}(B) \subset \mathscr{D}(C)$, and some results are obtained even for unbounded C. However, the more typical theorems concern the case $C \geq 0$ and compact, and we

suppose this condition satisfied from now on. (This forces the spectrum of $L(\lambda)$ to be symmetric in the real axis.) The most interesting feature of the investigation is the systematic use made of the relations between the spectral structure of $L(\lambda)$ and the quadratic operator equation

$$(*)\qquad Z^2+BZ+C=0.$$

Here is a slightly weakened version of a basic theorem. Let Λ, $\bar{\Lambda}$ be any partition of the non-real spectrum of $L(\lambda)$ into two disjoint sets, each the reflection of the other in the real axis. Then (*) possesses a bounded solution Z_Λ satisfying (1) $Z_\Lambda\mathscr{H}\subset\mathscr{D}(B)$, (2) $Z_\Lambda{}^*Z_\Lambda\leq C$, (3) the non-real spectrum of Z_Λ coincides with Λ. An application of this theorem yields the following. Suppose B is in the trace class and that

$$(Bx,x)^2<4(x,x)(Cx,x),\qquad x\neq 0.$$

Then $-\sum\Re\lambda_i\leq\operatorname{Tr}B$, where the sum is extended over all eigenvalues of $L(\lambda)$, counting multiplicities.

Suppose, on the other hand, that

$$(Bx,x)^2>4(x,x)(Cx,x),\qquad 0\neq x\in\mathscr{D}(B).$$

Then the spectrum of $L(\lambda)$ lies entirely on the negative real axis and the following is true: (*) has a unique solution Z_1 [Z_2] satisfying $Z_1{}^*Z_1\leq C$ [$Z_2{}^*Z_2\geq C$] and we have (a) $Z_2+Z_1{}^*=-B$, $Z_2{}^*Z_1=C$, (b) spec $L(\lambda)=$ spec $Z_1\cup$ spec Z_2, spec $Z_2\leq$ spec Z_1, (c) the eigenvectors x of Z_1 [Z_2] are eigenvectors of $L(\lambda)$ for eigenvalues λ such that $|\lambda|^2<(Cx,x)/(x,x)$ [$|\lambda|^2>(Cx,x)/(x,x)$], the case $|\lambda|^2=(Cx,x)/(x,x)$ being impossible.

Proofs are omitted or merely sketched, although enough is given to show that the above-mentioned basic theorem is an interesting application of the authors' work on "J-selfadjoint" operators [Heinz Langer, Math. Ann. **146** (1962), 60–85; MR **25** #1450; ibid. **152** (1963), 434–436; MR **28** #1492; and M. G. Kreĭn, #6314 above]. A detailed report is to appear in the "Proceedings of an International Symposium on the Application of Function Theory to the Mechanics of Continuous Media".

Lindenstrauss, Joram 6316

On the modulus of smoothness and divergent series in Banach spaces.

Michigan Math. J. **10** (1963), 241–252.

Given a Banach space X, we may introduce the notions of modulus of convexity $\delta_X(\varepsilon)$ and modulus of smoothness $\rho_X(\tau)$. Let $\delta_X(\varepsilon)=\frac{1}{2}\inf(2-\|x+y\|)$, $0\leq\varepsilon\leq 2$, where the infimum is taken over all x,y such that $\|x\|=\|y\|=1$ and $\|x-y\|=\varepsilon$. Let $\rho_X(\tau)=\frac{1}{2}\sup(\|x+y\|+\|x-y\|-2)$, $0\leq\tau$, where the supremum is taken over all x,y such that $\|x\|=1$, $\|y\|=\tau$. Let X^* denote the dual space of X.

Theorem 1: $\rho_{X^*}(\tau)=\sup_{0\leq\varepsilon\leq 2}(\frac{1}{2}\tau\varepsilon-\delta_X(\varepsilon))$. Corollary: $\rho_X(\tau)\geq(1+\tau^2)^{1/2}-1$ and if equality holds for all τ between 0 and 1, then X is an inner product space. Theorem 2: If $\{x_i\}_{i=1}^\infty$ is a sequence in X such that $\sum\pm x_i$ diverges for every choice of signs, then $\sum\rho_X(\|x_i\|)=\infty$.

It is shown that if $\delta_X(t)$ and $\rho_X(t)$ behave, for small t, as multiples of t, then under rather general conditions X is isomorphic to an inner product space.

Finally, an index of convergence and an index of divergence for a Banach space X are introduced and some properties are discussed.

Minty, George J.

Monotone (nonlinear) operators in Hilbert space.

Duke Math. J. **29** (1962), 341–346.

Let $\mathfrak{X}$ be a (real or complex) Hilbert space with … product $\langle x,y\rangle$. An operator F (not necessarily l[inear]) acting from $\mathfrak{D}\subset\mathfrak{X}$ into $\mathfrak{X}$, is called monoto[ne if] $\operatorname{Re}\langle x_1-x_2, F(x_1)-F(x_2)\rangle\geq 0$ for any $x_1,x_2\in\mathfrak{D}$ … fundamental result is that if F is a continuous mo[notone] operator, then the inverse operator $(I+F)^{-1}$, w[here I] is the identity operator, exists, is continuous … domain of definition, and is monotone. If, in addit[ion, F] is maximal, i.e., does not have an extension … preserves monotonicity, and if the set $\mathfrak{D}$ is open … $(I+F)^{-1}$ is defined everywhere on $\mathfrak{X}$.

The author gives some sufficient conditions th[at an] operator be monotone. In particular, if the set … convex and the derivative

$$\left[\frac{d}{dt}\operatorname{Re}\langle x_1-x, F(x+t(x_1-x))\rangle\right]_{t=0},$$

where t is real, exists and is non-negative for ar[bitrary] $x, x_1\in\mathfrak{D}$, then F is monotone.

On the basis of his results, the author is able to co…

the "graph" of F in the space $\mathfrak{X}\times\mathfrak{X}$ (endowed with the scalar product $\langle(x_1,y_1),(x_2,y_2)\rangle=\langle x_1,x_2\rangle+\langle y_1,y_2\rangle$) and to study in this space the relations $(x_1,y_1)M(x_2,y_2)$ and $(x_1,y_1)L(x_2,y_2)$ defined by

$$\operatorname{Re}\langle x_1-x_2,y_1-y_2\rangle \geq 0,\qquad \|x_1-x_2\| \geq \|y_1-y_2\|,$$

respectively. *I. Šragin* (RŽMat 1963 #6 B410)

Olubummo, A. 6320
A note on perturbation theory for semi-groups of operators.
Proc. Amer. Math. Soc. 15 (1964), 818–822.

A theorem of Miyadera [Tôhoku Math. J. (2) 11 (1959), 98–105; MR 21 #5903] gives a necessary and sufficient condition in order that a perturbation of a strongly continuous semigroup of positive contractions of an abstract L-space result in a strongly continuous semigroup of positive contractions dominating the unperturbed semigroup. The perturbation of the infinitesimal generator in this theorem is by means of a not necessarily bounded operator, whose domain contains that of the infinitesimal generator. The main result of the present paper can be considered as a generalization of the theorem of Miyadera to general Banach lattices, but it is actually more because the conditions characterizing the desired perturbing operators are somewhat simpler. These conditions become even simpler (the second main result) for bounded perturbations, still in the context of Banach lattices.

J. Gil de Lamadrid (Paris)

Saphar, Pierre 6321
Calcul fonctionnel et sous-espaces stables pour une application linéaire continue dans un espace de Banach.
C. R. Acad. Sci. Paris 258 (1964), 6055–6057.

For a continuous linear operator T on a (complex) Banach space E, $\operatorname{co}(T)$ denotes the largest subspace of E such that $T(\operatorname{co}(T))=\operatorname{co}(T)$. $S_1(n,p;T)$ is the open subset of those points z in the complex plane such that

$$\dim\ker(T-z)=n,\qquad \operatorname{codim}(T-z)(E)=p,$$

$$\ker(T-z)\subset\operatorname{co}(T-z).$$

For any connected component D of $S_1(n,p;T)$ there is a discrete set δ in D and a holomorphic $\mathscr{L}(E)$-valued function R on $D-\delta$ such that

$$(T-z)R(z)(T-z)=T-z,\qquad R(z)(T-z)R(z)=R(z),$$

$$R(z)-R(z')=(z-z')R(z)R(z'),$$

and $\operatorname{Im}R(z)$ and $\ker R(z)$ are topological complements of $\ker(T-z)$ and $\operatorname{Im}(T-z)$, respectively; the set δ can be chosen to avoid any compact subset of D. Using this function R, a functional calculus is established,

$$f\to-\frac{1}{2\pi i}\int_\gamma f(t)R(t)\,dt,$$

where f is holomorphic in a neighborhood of any compact and open subset of the complement of $D-\delta$. As an application, the existence of invariant subspaces tied to properties of the spectrum is obtained; furthermore, a discussion of the equation $(T-z)x=y$, $z\in D$, is given. No proofs are presented. *L. Bungart* (Berkeley, Calif.)

Sasser, D. W. 6322
Quasi-positive operators.
Pacific J. Math. 14 (1964), 1029–1037.

Let B denote a partially ordered real Banach space whose positive cone K is closed and fundamental in B. A (bounded) operator T in B is called quasi-compact if it has spectral radius $r(T)>0$ and if for some n and some operator V with $r(V)<r(T)^n$, T^n-V is compact. If, in addition, T is positive (i.e., if $T(K)\subset K$), then the peripheral spectrum $\sigma(T)\cap\{\lambda:|\lambda|=r(T)\}$ of T has a number of interesting properties [cf. Krein and Rutman, Amer. Math. Soc. Transl. No. 26 (1950); MR 12, 341; and the reviewer, Pacific J. Math. 10 (1960), 1009–1019; MR 22 #5893]; these are generalized here to the case of quasi-compact, quasi-positive operators in B. (T is called quasi-positive if for each $x\geq 0$ in B and each continuous linear form $x^*\geq 0$ on B, one has $x^*(T^kx)\geq 0$ whenever $k\geq n(x,x^*)$.) The idea of the proof is that Pringsheim's theorem on the singularities of a power series with non-negative scalar coefficients remains valid when all but a finite number of these coefficients are ≥ 0.

H. H. Schaefer (Tübingen)

Shinbrot, Marvin 6323
A fixed point theorem, and some applications.
Arch. Rational Mech. Anal. 17 (1964), 255–271.

Let $\mathfrak{H}$ be a separable Hilbert space; for $r>0$, let $\mathfrak{S}_r$ and $\mathfrak{B}_r$ denote the (open) sphere and (closed) ball of radius r with center at the origin. Let $A:\mathfrak{H}\to\mathfrak{H}$ be continuous with respect to the weak topology in $\mathfrak{H}$. The author proves (main theorem) that if there is an $r>0$ such that $\operatorname{Re}\langle Ax,x\rangle\leq\|x\|^2$ for all $x\in\mathfrak{S}_r$, then A has a fixed point in $\mathfrak{B}_r$. The main tool is the finite-dimensional special case, proved with (Weierstrass) polynomial approximations to A in a way reminiscent of existing analytical proofs of Brouwer's theorem. Much briefer proofs can be given by a degree argument (noted by the author) or Brouwer's theorem (not noted). Various corollaries are considered.

"Applications" are given to the proofs of other abstract theorems, e.g., let $A:\mathfrak{H}\to\mathfrak{H}$ be continuous in the weak topology and suppose $\operatorname{Re}\langle A(sx),x\rangle$ is a monotonically increasing function of the real variable s for all x and large enough s. Let L be either the identity or a positive linear operator with compact inverse. Then $(L+F)$ is "onto" $\mathfrak{H}$. More concrete applications are given to proofs of existence of solutions of quasilinear partial differential equations (in divergence form) satisfying certain "monotonicity conditions". In contrast to recent related work of F. Browder, the coefficients are not allowed to depend on the highest-order derivatives; however, the author's hypotheses are weaker in some other respects. A more concrete application is given to the stationary Navier-Stokes equation in n dimensions with $n\leq 4$.

Simpson, James E. 6324
Nilpotency and spectral operators.
Pacific J. Math. 14 (1964), 665–672.

Dunford's theory of spectral operators has been extended to operators on locally convex spaces, and this paper carries over some of the Banach-space theorems of the reviewer [same J. 9 (1959), 1223–1231; MR 21 #7442] to this more general setting.

Takesaki, Masamichi 6332

A complement to "On the unitary equivalence among the components of decompositions of representations of involutive Banach algebras and the associated diagonal algebras".

Tôhoku Math. J. (2) **16** (1964), 226–227.

The author shows the following. Let A_1 and A_2 be two maximal abelian subalgebras of a von Neumann algebra M. Let $e_1\,[e_2]$ be a non-zero projection in $A_1\,[A_2]$. If there exists a central projection z of M such that $e_1 \leq z$ and $e_2 \leq I-z$, then A_1e_1 and A_2e_2 are unrelated. Hence if A_1e_1 and A_2e_2 are similar, then e_1 and e_2 have the same central carriers. *B. Yood* (Eugene, Ore.)

Vala, Klaus 6333

On compact sets of compact operators.

Ann. Acad. Sci. Fenn. Ser. A I No. 351 (1964), 9 *pp.*

This note modifies an argument due to S. Kakutani [J. Math. Soc. Japan **3** (1951), 228–231; MR **13**, 355] to obtain a different formulation for Ascoli's theorem. Let A be a set and let F be a metric space; a mapping $f: A \to F$ is "precompact" if the set $f(A)$ is precompact (= totally bounded) in F. The collection $K(A, F)$ of all precompact maps of A into F is a metric space under $d(f, g) = \sup\{d(f(x), g(x)); x \in A\}$. The new form of Ascoli's theorem is: A subset $H \subseteq K(A, F)$ is precompact if and only if (1) $H(x) = \{f(x): f \in H\}$ is precompact in F, and (2) H has "equal variation" (in the sense that for $\varepsilon > 0$ there is a finite partition $\{A_j\}$ of A such that if $x, y \in A_j$, $f \in H$, then $d(f(x), f(y)) < \varepsilon$). As an application, the author proves a generalization of Schauder's theorem on the adjoint of a compact operator. A special case of his result is the following. Let E be a Banach space and let A, C be non-zero elements of $L(E)$, the normed algebra of bounded linear operators on E. Then the map $T \to ATC$ is a compact operator of $L(E)$ into $L(E)$ if and only if both A and C are compact operators. An extension of the theorem of Dini is also given. *R. G. Bartle* (Urbana, Ill.)

Varopoulos, N. Th. 6334

A note on the abstract Wiener-Pitt phenomenon.

Proc. Cambridge Philos. Soc. **61** (1965), 297–298.

Suppose that M is a semisimple commutative Banach algebra with unit and with an involution i defined on it. Suppose that $L \subset M$ is a closed star ideal such that L is a completely symmetric Banach algebra relative to $i\,|\,L$. Identify the maximal ideal space $\mathcal{M}_L$ with a subspace of $\mathcal{M}_M$. The author says that the Wiener-Pitt phenomenon occurs if and only if there is an $m \in M$ and a $\chi_0 \in \mathcal{M}_M$ such that $m(\chi_0) = 0$ and yet $\inf\{|m(\chi)| : \chi \in \mathcal{M}_L\} > 0$. The following theorem is proved; it adds to previous results by the author in this context: If the Wiener-Pitt phenomenon does not occur, then $\mathcal{M}_L$ is dense in $\mathcal{M}_M$. *K. H. Hofmann* (New Orleans, La.)

Xia, Dao-xing [Hsia, Tao-hsing] 6335

On locally bounded topological algebras.

Acta Math. Sinica **14** (1964), 238–251 (*Chinese*); *translated as Chinese Math.* **5** (1964), 261–276.

A locally bounded algebra is a topological algebra which, as a topological linear space, is a locally bounded space, i.e., possesses a basis of neighbourhoods of zero consisting of bounded sets. The topology of a locally bounded algebra
is always metrizable, and its metric may be given b
of a p-homogeneous norm $\|ax\| = |a|^p\|x\|$ for any
and vector x, where p is a fixed real number sa
$0 < p \leq 1$; other properties are the same as in the c
homogeneous norm. In the case when the algebra
tion is complete or its multiplication is jointly con
the p-homogeneous norm may be chosen in such
that it is submultiplicative; in this case, the al
called a p-normed algebra. The theory of locally b
algebras was given earlier by the reviewer [Studi
19 (1960), 333–356; MR **22** #A4033; ibid. **21** (1
203–206; MR **25** #4381; ibid. **21** (1961/62), 3
MR **25** #4380; Colloq. Math. **10** (1963), 57–60;
#6809]. It was shown [MR **25** #4380, loc. cit.] that i
$\lim \sqrt[n]{\|x^n\|}$, where $\|x\|$ is a submultiplicative p-homo
norm, then $\|x\|_s$ is a homogeneous pseudonorm,
follow certain basic facts concerning the algebra i
tion. In the paper under review the author ma
observation that for a p-normed algebra $(A, \|\ \|$
exists a maximal homogeneous pseudonorm $|\ |$ sa
$|x|^p \leq \|x\|$, called a support pseudonorm of $\|\ \|$. C
$\|x\|_s \leq |x|^p \leq \|x\|$, and the support pseudonorm i
defined as $|x| = \sup_{f \in F} |f(x)|$, where F is the famil
linear functionals defined on A and satisfying $|f(x)|$
thus $(\bar{A}, |\ |)$, the completion of A in $|\ |$, is a
algebra having "the same" maximal ideal sp
$(A, \|\ \|)$; observe that $\|x\|_s = (\lim \sqrt[n]{\|x^n\|})^p$. By
of this algebra the author obtains some pro
p-normed algebras. Some results are given also
normed algebras with involutions, called in the tra
"convolutions". *W. Żelazko* (W

Glicksberg, I. 6337

Maximal algebras and a theorem of Radó.

Pacific J. Math. 14 (1964), 919–941.

The theorem of Radó referred to in the title is the following. Let f be a continuous function on $D=\{|z|\le 1\}$, and let $K=\{z\in D; f(z)=0\}$. If f is analytic on $\{|z|<1\}-K$, then f is in fact analytic throughout the interior of D. The author gives a new proof, which is roughly as follows. If A_1 is the algebra of continuous functions on D which are analytic on the interior of D, it is known that A_1 is a maximal subalgebra of $C(\Gamma)$, $\Gamma=\{|z|=1\}$. Let B be the algebra of continuous functions on D which are analytic on $\{|z|<1\}-K$. Then B is a subalgebra of $C(\Gamma)$ which contains A_1. By proving that the Šilov boundary of B is Γ, the author verifies that B is a proper closed subalgebra of $C(\Gamma)$ and thus $B=A_1$, proving Radó's theorem.

Beyond this, the author provides a broad investigation of the implications of various types of maximality, applies his methods further in order to obtain a type of Schwarz lemma for Banach algebras, and studies integral closures of algebras of functions. The main tool is the following lemma. Let A be a uniform algebra with spectrum M and let X be a boundary for A. Let V be a relatively open subset of X. Suppose $g\in A$ peaks within X on a nonvoid subset of V, and let $\alpha=\sup\{|g(x)|; x\in X-V\}$. Then any $f\in A$ vanishing on V also vanishes on $\{m\in M; |g(m)|>\alpha\}$.

H. Rossi (Waltham, Mass.)

Krivine, Jean-Louis 6338

Quelques propriétés des préordres dans les anneaux commutatifs unitaires.

C. R. Acad. Sci. Paris 258 (1964), 3417–3418.

A pre-order in a commutative algebra A over the reals is a subset Ω closed under addition and multiplication, containing the non-negative reals but not -1. This differs from the concept in the author's paper [J. Analyse Math. 12 (1964), 307–326] in not assuming that Ω contains x^2 for all x in A. However, every maximal archimedean pre-order does contain all squares, and so the author's other results apply and can be improved. In particular, A is represented by continuous real-valued functions on the space of all maximal pre-orders containing a fixed archimedean Ω. If such a function is non-negative and not zero, then the corresponding element of A is $\ge 1/n$ in the pre-order Ω for some positive integer n. Suitable choices of Ω yield theorems such as the following. Every polynomial $H(X_1,\cdots,X_n)$ with real coefficients which is strictly positive on the unit cube is expressible as a polynomial in $X_1,\cdots,X_n$ and $1-X_1,\cdots,1-X_n$ with positive coefficients; and every power series which is absolutely convergent and strictly positive on $[-1,1]$ is a finite sum $\sum_i \exp\varphi_i(x)$, with φ_i a power series absolutely convergent on $[-1,1]$.

Barros Neto, J. [Barros-Neto, J.] 6339

Spaces of vector valued real analytic functions.

Trans. Amer. Math. Soc. 112 (1964), 381–391.

Given an open set K in a finite-dimensional vector space, a locally convex topological vector space E, and a notion of smooth mapping, one generally considers "weakly smooth" and "strongly smooth" mappings of K into E. The question here is of the equivalence of these notions. For "smooth" interpreted as C^∞, or complex analytic, Grothendieck [*Espaces vectoriels topologiques*, Inst. Mat. Pura e Apl., Univ. de São Paulo, São Paulo, 1954; MR 17, 1110] answered the question affirmatively when E is complete. The author is concerned with real analytic mappings; he shows that completeness is not enough, but having a Fréchet space as strong dual suffices. More precisely, we have the following definitions. Let U be an open set on the real line and E a complete topological vector space, with E' its dual. Let φ be a mapping of U into E. φ is weakly analytic at $t_0\in U$ if for all $f'\in E'$, $\langle\varphi(t), f'\rangle$ is an analytic function in a neighborhood of t_0. φ is strongly analytic if there exists $a_p\in F$ for $p\in Z$ such that $\varphi(t)=\sum a_p(t-t_0)^p$ uniformly in a neighborhood of t_0. The author introduces the notion of quasi-(DF) space which generalizes (DF) and proves the equivalence of weak and strong real analyticity in this case. He then considers natural topologies on these spaces of mappings, and proves that they coincide in case E has a Fréchet space as dual. Finally, he considers mappings of U into $L(E,F)$, where E, F are topological vector spaces. Here there are three notions of analyticity to consider; in case E is barrelled and F a complete quasi-(DF) space, these all coincide.

Barros-Neto, J. 6340

The Dirichlet problem for homogeneous elliptic operators in a half space.

Bull. Amer. Math. Soc. 70 (1964), 798–802.

In a recent series of papers [Ann. Scuola Norm. Sup. Pisa (3) 16 (1962), 1–44; MR 26 #4049; and articles there cited] Lions and Magenes have given a great number of precise results on the mapping by elliptic operators of various function spaces on a bounded region of Euclidean space. The present work considers the same questions in a half-space, where new difficulties arise. The following spaces are introduced. R_+^n is the half-space $x_n>0$ of R^n. If $m\ge 0$ is an integer, then $D^{k,m}(R_+^n)=\{u\in L^{q(m)}(R_+^n)$: $D^rD^pu\in L^{q(m-j)}(R_+^n)$, where $0\le|r|\le k$, $0\le j=|p|\le m$, $1/q(j)=\frac12-j/n\}$. $D_0^m(R_+^n)$ is the closure in $D^m(R_+^n)$ of $C_c^\infty(R_+^n)$; $D^{-m}(R_+^n)$ is the dual of $D_0^m(R_+^n)$. If $-n+1<2s<n-1$, then $D^s(R^{n-1})$ is the completion of $C_c^\infty(R^{n-1})$ in the norm $\|\phi\|_{D^s(R^{n-1})}=(\int_{R^{n-1}}|\xi|^{2s}|\phi^\wedge(\xi)|^2d\xi)^{1/2}$, with $\phi^\wedge$ the Fourier transform of ϕ.

Let $\gamma_j\phi(x_1,\cdots,x_{n-1})=(\partial^j\phi/\partial x_n^j)(x_1,\cdots,x_{n-1},0)$, and consider $Au=\sum_{|p|=|r|=m}D^ra_{rp}D^pu$, where a_{rp} is C^∞ and bounded on $\bar R_+^n$, and $\int_{R_+^n}(Av)\bar v\ge c\|v\|^2_{D^m(R_+^n)}$ for all v in $C_c^\infty(R_+^n)$. Theorem: The map $u\to(Au,\gamma_0u,\cdots,\gamma_{m-1}u)$ extends uniquely from $C_c^\infty(\bar R_+^n)$ to an isomorphism of $D^m(R_+^n)$ onto $D^{-m}(R_+^n)\times\prod_{j=0}^{m-1}D^{m-j-1/2}(R^{n-1})$; if f is in $D^{1-m}(R_+^n)\cap D^{-m}(R_+^n)$, then the unique solution u in $D_0^m(R_+^n)$ of $Au=f$ lies in $D^{1,m}(R_+^n)$. The isomorphism is extended to a class of spaces by interpolation.

Bittner, R. 6341

Algebraic and analytic properties of solutions of abstract differential equations.

Rozprawy Mat. 41 (1964), 63 pp.

The scope of this paper is much wider than is indicated by the title. The author considers a linear map S from a linear space C^1 into another linear space C^0, with $C^1\subset C^0$, with a right inverse T, i.e., T is a linear map from $C^0\to C^1$ such that $ST=$ identity, and $Tf=0$ if and only if $f=0$. The author calls S a derivative, T an integral, and proceeds to

develop a theory concerning such abstract differential equations. The first section is algebraic only, while the second section introduces spaces in which various types of convergence are defined, and the author studies abstract equations in such spaces. The development is clear, elegant, and natural. Rather than attempt to state the results, it would perhaps give a better idea of the significance of this paper if the applications considered by the author are listed: Ordinary or partial differential and difference equations, differential equations involving Mikusiński's operational calculus, asymptotic series, various difference formulas for interpolation, Schauder's and Banach-Caccioppoli's fixed-point theorems, and the Kojima-Schur and Toeplitz summation theorems.

The index of solutions of nonlinear equations in Banach space.

Acta Math. Sinica **13** (1963), 315–322 (*Chinese*); *translated as Chinese Math.* **4** (1964), 341–350.

Let X, Y, Z be Banach spaces and $F: X \times Y \to Z$ be such that $F(x_0, y_0) = 0$. If the partial derivative $F_x'(x_0, y_0)$ has n-dimensional null space and its adjoint has m-dimensional null space, there is a one-one correspondence between the solutions of $F(x, y) = 0$ near (x_0, y_0) and the solutions of a finite-dimensional non-linear equation. The Brouwer index is considered for isolated solutions of this bifurcation equation. The equality of this Brouwer index and the Leray-Schauder index of a related mapping is established when both indices are defined. This note is closely related to papers of Jane Cronin [Trans. Amer. Math. Soc. **69** (1950), 208–231; MR **12**, 716; ibid. **76** (1954), 207–222; MR **16**, 47].

On the spectrum of non-selfadjoint differential operators. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 29–32.

Let A be a selfadjoint operator in a Hilbert space and let B have domain $D(B) \supset D(A)$. Suppose $\|Bf\| \leq a\|Af\| + b\|f\|$ for $0 \leq a < \frac{1}{2}$, $b > 0$, and $f \in D(A)$. Moreover, suppose G is a region in the complex plane and m is an integer such that $(B(A-z)^{-1})^m$ is completely continuous for $z \in G$ and that $I + B(A-z)^{-1}$ has a bounded inverse for $z \in G$. Then the operator $T = A + B$ with $D(T) = D(A)$ is closed and $\sigma(T) \cap G$ consists of isolated eigenvalues of finite multiplicity. Using this result, the authors state some results concerning the perturbation of a differential operator by adding a non-selfadjoint differential operator of lower order.

Mitropol′skiĭ, Ju. A. 6[...]

A study of the integral manifold for a system of non-lin[ear] equations in Hilbert space which are close to equati[ons] with variable coefficients. (Russian. English su[m]mary)

Ukrain. Mat. Ž. **16** (1964), 334–338.

The author considers a system of differential equations [of] the form (1) $d\phi/dt = \omega(t) + P(t, \phi, h, \varepsilon)$, $dh/dt = H(t)h$ [+] $Q(t, \phi, h, \varepsilon)$, where ϕ is a scalar, h is an element of a Hilb[ert] space H, P and Q are continuous in their argumen[ts,] bounded in t, ϕ for all t, ϕ and Lipschitzian in h, w[ith] bounds and Lipschitz constants which approach zero [as ε] and h approach 0. The major assumption is that [the] operator equation $dU/dt = H(t)U(t)$, with $U(t_0) = E$, [the] identity operator, is uniformly exponentially asym[p]totically stable as $t \to +\infty$ in the operator norm. Using [the] method developed by Bogoljubov and the author [for] showing the existence of stable integral manifolds [for] systems in the form (1) (see Hale [*Oscillation in non-lin[ear] systems*, McGraw-Hill, New York, 1963; MR **27** #4[...] for a reference in English), it is then shown that (1) ha[s a] stable one-dimensional integral manifold. It would be [of] interest if the author gave some applications indicati[ng] how a system of the form (1) might occur and some inte[r]pretation of the results in terms of the applications.

A. Stokes (Washington, D.[C.)]

Sirčenko, Z. F. 6347

Extension of a theorem of N. N. Bogoljubov to the case of a Hilbert space. (Russian. English summary)

Ukrain. Mat. Ž. **16** (1964), 339–350.

The author considers an equation in Hilbert space in standard form (1) $dx/dt=\varepsilon X(t,x)$, where x, $X(t,x)$ are functions with values in a Hilbert space H, and ε is a small parameter. The author extends the method of averaging of Krylov and Bogoljubov to (1), making the usual assumptions that the averaged equation (2) $dy/dt=\varepsilon X_0(y)$ exists, has an equilibrium point y_0, and that the infinite matrix $\partial X_0(y)/\partial y$ at $y=y_0$ has no eigenvalue with zero real part. Following the proof given by Bogoljubov and Mitropol'skiĭ, the author obtains the standard results concerning the existence and stability of an almost periodic solution of (1). It would be of some interest to see some applications of these results, i.e., some source for equations of the form (1), and some interpretation of the above results.

A. Stokes (Washington, D.C.)

Trenogin, V. A. 6348

Existence and asymptotic behaviour of solutions of "solitary wave" type for differential equations in a Banach space. (Russian)

Dokl. Akad. Nauk SSSR **156** (1964), 1033–1036.

The author deals with the boundary-value problem (1) $-d^2y/d\eta^2+Ay=F(\lambda,y)$, $-\infty<\eta<\infty$, $\lim_{\eta\to\pm\infty} y(\eta)=0$, where y is an element of a Banach space E, λ is a real parameter, A is a closed linear unbounded operator whose domain is dense in E, $F(\lambda,y)$ is a nonlinear operator in E, analytic in λ, y in the neighborhood of the point $(\lambda,0)$ for all λ, with $F(\lambda,0)=0$. The problem (1) always has the trivial solution. The object is to give conditions under which for some $\lambda=\lambda_0$ there exist non-trivial solutions as well. The basic methods are similar to those used by A. M. Ter-Krikorov and the author for a boundary-value problem for elliptic equations [Mat. Sb. (N.S.) **62** (104) (1963), 264–274; MR **28** #3266]. In preliminary lemmas, the differential equation $-d^2z/d\xi^2+Bz=h(\xi)$, subject to the boundary condition $\lim_{\xi\to\pm\infty} z=0$, is solved "explicitly" with the aid of the theory of semi-groups, under conditions on the closed linear operator B which permit the use of the Hille-Yoshida-Phillips theorem. The conditions of the principal theorem involve the concept of a generalized Jordan chain of length p of a linear operator B with respect to the analytic operator Φ and are too complicated to be given here.

D. H. Hyers (Los Angeles, Calif.)

Valikov, K. V. 6349

Characteristic indices of solutions of differential equations in a Banach space. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 1010–1013.

The author considers an equation of the form (1) $dx/dt=Ax$, x in a Banach space X, and A a closed operator with domain $D(A)\subset X$ and values in X, satisfying auxiliary conditions so that A generates an analytic semi-group e^{At}, $t>0$. The author defines, following Lyapounov, the characteristic index $\mu(x)$ of a function $x(t)$, with values in X. The author's first two theorems relate the characteristic indices of solutions of (1) to the real part of the spectrum of A, thereby extending results of M. G. Krein when A is assumed bounded [Uspehi Mat. Nauk **3** (1948), no. 3 (25), 166–169; MR **10**, 128]. The author then considers the equation (2) $dx/dt=Ax+h(x,t)$, where h is defined for $t\geq 0$, $x\in D(A_0^\alpha)$, $0\leq\alpha<1$, $h(0,t)=0$, and $h(A_0^\alpha,x,t)$ is continuous for $x\in X$, $t\geq 0$. Here $A_0=z_0I-A$, where z_0 is such that the spectrum of A is contained in an angular sector opening to the left centered at z_0. The remaining five theorems then give conditions for the existence of solutions of (2) on finite intervals, then on infinite intervals, and finally, various relations are given between the real part of the spectrum of A and $\mu(A_0^\alpha x)$, where x is a solution of (2).

Bass, Jean 6350

Espaces de Besicovitch, fonctions presque-périodiques, fonctions pseudo-aléatoires.

Bull. Soc. Math. France **91** (1963), 39–61.

Author's summary: "Les fonctions complexes $f(t)$ telles que la moyenne quadratique

$$\lim_{T\to\infty} T^{-1}\int_0^T |f(t)|^2\,dt$$

existe ne constituent pas dans leur ensemble un espace vectoriel. Mais on peut les grouper en espaces vectoriels incomplets E. Dans un espace E, toute suite de Cauchy converge vers une limite, et la limite obtenue est un prolongement de l'espace E. Une suite de Cauchy particulière permet de représenter la classe des translatées d'une fonction $f(t)$ de E par la formule

$$f(t+h)=\int_{-\infty}^{\infty}\exp(2i\pi\omega h)\,Y(t,d\omega),$$

où $Y(t,\Delta)$ est une fonction spectrale telle que la moyenne de $\bar{Y}(t,\Delta)Y(t,\Delta')$ soit nulle lorsque Δ et Δ' sont disjoints. Suivant les propriétés de $Y(t,\Delta)$, on classe les fonctions f en fonctions presque-périodiques, fonctions pseudo-aléatoires, fonctions singulières."

CALCULUS OF VARIATIONS

See also 5829, 6158, 6402, 6446, 6972, 6973, 6976, 6977.

Bolonkin, O. O. 6352

Optimization of the parameters of variational problems. (Ukrainian. Russian and English summaries)

Dopovidi Akad. Nauk Ukrain. RSR **1964**, 580–582.

In this paper the author considers Mayer's problem of the variational calculus regarding the extremum of the functional $I=G[c,x_1,y(x_1),x_2,y(x_2)]$, with differential constraints $\Phi_i\equiv \dot y_i-f_i(c,x,y,u)=0$, $i=1,2,\cdots,n$, and with boundary conditions $g_k[c,x_1,y(x_1),x_2,y(x_2)]=0$, $k=1,2,\cdots,p\leq 2n+1$. Here $y(x)=\{y_i(x)\}$ is a vector function, $c=\{c_1,c_2,\cdots,c_l\}$ an l-measured vector-constant subject to the constraints $\varphi_m(c)=0$, $m=1,\cdots,q<l$, and $\varphi_\xi^*(c)\leq 0$, $\xi=1,\cdots,\zeta$. Three theorems are established

and discussed on the necessary and sufficient conditions for the relative and absolute minimum of the above functional with the given constraints.

The proofs of these theorems are very weak, so that the treatment is difficult to comprehend.

D. P. Rašković (Belgrade)

Faedo, Sandro 6353

Semicontinuità e quasi-regolarità per gli integrali di Fubini-Tonelli.

Ann. Scuola Norm. Sup. Pisa (3) 18 (1964), 361–383.

A Fubini-Tonelli integral is a double integral of the form $I(y_1, y_2) = \int_a^b \int_c^d f[x, z, y_1(x), y_2(z); y_1'(x), y_2'(z)]\, dx dz$, and this double integral is here interpreted in a Weierstrass sense rather than as a Lebesgue integral. It is (for fixed f) a functional depending on a pair of non-parametric curves $y_1(x)$ $(a \leq x \leq b)$ and $y_2(z)$ $(c \leq z \leq d)$. Its study in no way reduces to that of the ordinary single variational integrals, and it was thought until now that it behaves quite differently from these. Indeed, Magenes [same Ann. (3) 2 (1948), 1–38; MR 12, 267; ibid. (3) 3 (1949), 95–131; MR 12, 267] established the validity of a strange semicontinuity condition, unrelated to convexity, and which has no parallel for single integrals. All this turns out, however, to have been a will-o'-the-wisp, for the author shows, surprisingly enough, that the Magenes condition is necessary only if we admit curves which reduce to single points. By excluding such degenerate non-parametric curves, the author is able to establish semicontinuity theorems which are natural analogues of those for single integrals. His necessary condition for semicontinuity is positive quasiregularity, and his sufficient condition consists of this, together with a uniform continuity condition for f, uniformity being in respect of the arguments y_1', y_2'.

L. C. Young (Madison, Wis.)

Fichera, Gaetano 6354

Semicontinuity of multiple integrals in ordinary form.

Arch. Rational Mech. Anal. 17 (1964), 339–352.

The author establishes a semicontinuity of considerable generality for non-parametric integrals of the form $\int f(x, Mu, Lu)\, dx$ taken over a bounded open subset A of Euclidean r-dimensional space. Semicontinuity is in regard to the weak topology in u, and here u takes values in a Banach space, while L, M are linear operators, not necessarily differential operators, which transform U into two vector-valued functions of x, with components in L^p for some $p > 1$. It is assumed that the integrand $f(x, y, z)$ is continuous in (x, y, z) and convex in z, and, moreover, that it possesses a convex minorant of the form $f_0(z)$ which is large compared with (Z) for large z. To these hypotheses, there is added a compactness condition in regard to M, to account for the absence of any convexity hypothesis of f in the vector y. The author's discussion is particularly well motivated, and he derives a corresponding existence theorem for an attained minimum.

Let $\mathcal{F}^*E$ denote the reduced boundary of a set $E \subset R$[…] finite perimeter $P(E)$, in the sense of De Giorgi [Rice[…] Mat. 4 (1955), 95–113; MR 17, 596]. Let $A \subset R^n$ […] bounded and open. Suppose that $(\mathcal{F}^*E) \cap A$ has m[…]mum $(n-1)$-area in the sense that $P(E) \leq P(E')$ for e[…] E' such that $E - A = E' - A$. De Giorgi [Seminari[…]

Mat. Scuola Norm. Sup. Pisa (1960–61), pp. 1–57, Editrice Tecnico Scientifica, Pisa, 1961] showed that any $x \in (\mathscr{F}^*E) \cap A$ has a neighborhood U such that $(\mathscr{F}^*E) \cap U$ is an analytic hypersurface. Let $S(E)$ be the set of all $x \notin \mathscr{F}^*E$ such that x is a limit point of $\mathscr{F}^*E$ and $(\mathscr{F}^*E) \cap A$ has minimum $(n-1)$-area for some open set A containing x. $S(E)$ is called the singular set. It is an open question whether $S(E)$ is always empty. In these three papers some partial results about it are obtained.

In the first paper it is shown that if $x = 0 \in S(E)$, then there exists a cone L with vertex 0 such that $\mathscr{F}^*L$ locally has minimum $(n-1)$-area and $0 \in S(L)$. The cone L is the limit, locally in measure, of E_{ρ_k} for a suitable sequence ρ_k tending to 0, where E_ρ is the ρ^{-1} homothetic image about 0 of E.

The second paper begins with a discussion of sets locally of finite perimeter. Then it is shown that if L is as above and 0 is an accumulation point of $S(L)$, then there exists a cylinder M such that $\mathscr{F}^*M$ locally has minimum $(n-1)$-area and $0 \in S(M)$.

In the third paper some results about cartesian products of sets of finite perimeter are proved. The results quoted above then imply that if $S(E)$ is not discrete for some $E \subset R^n$, then there exists a cone $N \subset R^{n-1}$ locally of minimum $(n-2)$-area such that $0 \in S(N)$. For $n \leq 3$ it is shown that $S(E)$ is always empty; the reviewer gave a different proof of this fact [Rend. Circ. Mat. Palermo (2) 11 (1962), 69–90; MR 28 #499]. Therefore, when $n = 4$, $S(E)$ is always a discrete set.

Guggenheimer, H. 6358

Ein Axiomensystem für die euklidische Geometrie.

Elem. Math. **19** (1964), 126–131.

Es wird ein Axiomensystem von einfacher algebraischer Struktur für die reelle Euklidische Geometrie aufgestellt. Die Axiome kennzeichnen im wesentlichen kollineare und nicht kollineare Lage von drei Punkten, die Vollständigkeit der Ebene und die Gültigkeit des Pythagoraischen Theorems. Obwohl in die Formeln dieses Axiomensystems nur gerade Potenzen der Entfernungen je zweier Punkte eingehen, können gerichtete Strecken in natürlicher Weise erklärt werden. Ein wesentlicher Teil der metrischen Euklidischen Geometrie (und der projektiven Geometrie) über einem reellen Zahlkörper beliebiger Charakteristik $p \neq 2$ kann so leicht entwickelt werden. Wird ein angeordneter Körper (der Charakteristik Null) zugrunde gelegt, so sind auch die üblichen Axiome der Anordnung und der Winkeladdition einfach zu beweisende Sätze. Für Körper der Charakteristik 2 decken sich Parallelismus und Orthogonalität, die Existenzsätze bereiten jedoch einige Schwierigkeiten.

On models of betweenness. (Russian. Estonian and English summaries)

Eesti NSV Tead. Akad. Toimetised Füüs.-Mat. Tehn.-tead. Seer. **13** (1964), 200–209.

An axiom system of geometry is given in terms of a ternary relation, called betweenness. It is then proved that in the two-dimensional case every model of this axiom system is a partial plane, and in case of dimension n greater than two, every model is isomorphic to a convex region of an n-dimensional linear space over an ordered division ring.

★Homographies, quaternions and rotations.

Oxford Mathematical Monographs.

Clarendon Press, Oxford, 1964. xiv + 116 pp. $5.60.

Cet ouvrage comble une lacune de la littérature mathématique puisqu'il reprend et coordonne un grand nombre de propriétés dont certaines ne se trouvent guère que dans les mémoires originaux parfois anciens et souvent peu accessibles au lecteur moyen; de plus l'exposé ne suppose que peu de connaissances préalables et s'adresse ainsi à un public étendu. A partir de la théorie des homographies unidimensionnelles, permettant la représentation des rotations de la sphère, on passe aux groupes finis de rotation et ainsi à l'étude des polyèdres réguliers. Une étude parallèle des quaternions conduit à la théorie des polytopes, qui constitue la partie la plus importante de l'ouvrage. Enfin le dernier chapitre traite des groupes d'involution et constitue la partie la plus originale, apportant des vues nouvelles sur la théorie des singularités des surfaces algébriques à laquelle l'auteur a consacré d'importants travaux. On se doit de souligner la présentation de modèles qui fait de cet instrument de travail "un beau livre".

Teoria di Galois, fibrazioni proiettive e geometrie [non] desarguesiane.

Ann. Mat. Pura Appl. (4) **64** (1964), 1–76.

L'autore ha suddiviso in tre parti questa sua volumi[nosa] e densa Memoria, complementare all'altra scritta [con]temporaneamente [Math. Ann. **154** (1964), 195–[256;] MR **29** #2697].

Nella 1ª parte (nn. 1–20), di carattere introduttivo e di contenuto prevalentemente algebrico, si occupa delle estensioni finite e separabili di un campo. Sia δ una tale estensione, propria, semplice, commutativa, algebrica e di grado n del campo γ, e sia $u_1, \cdots, u_n$ una sua base, cosicchè ogni elemento ξ di δ ha una espressione del tipo $\xi = x_1u_1 + \cdots + x_nu_n$, con le $x_1, \cdots, x_n$ variabili in γ. Sia inoltre δ^* il sovracorpo di δ e di γ, di decomposizione della equazione algebrica coi coefficienti in γ che definisce l'ampliamento da γ a δ. L'autore introduce uno spazio proiettivo ad $n-1$ dimensioni $S_{n-1} = \{(x_1, \cdots, x_n)\}$ su γ e fa vedere, sfruttando le costanti di struttura della base di δ su γ, come ad ogni cambiamento della base resti associata un'omografia dell' S_{n-1} in sè, mentre alla estensione stessa resta associata (in modo indipendente dalla base) una trasformazione cremoniana T, involutoria e di grado $n-1$ dell' S_{n-1}, le cui varietà fondamentali costituiscono la traccia di un simplesso rappresentabile (nell'ampliamento di S_{n-1} che si ottiene pensando le $x_1, \cdots, x_n$ variabili in δ^*) annullando la "norma" di ξ rispetto a γ. D'altra parte ad ogni estensione del tipo suddetto resta associata anche un'algebra A, commutativa, associativa e dotata di modulo, gli elementi della quale sono le stesse espressioni $\xi = x_1u_1 + \cdots + x_nu_n$, dove però ora le u_i si interpretino come puri simboli (legati dalle relazioni di struttura) e le x_i si pensino variabili in un sovracorpo χ di γ. Giovandosi ancora della considerazione di uno spazio proiettivo $S_{n-1} = \{(x_1, \cdots, x_n)\}$, l'autore affronta lo studio dei nullifici di A, allo scopo di precisarne ulteriormente la struttura. Si può supporre che χ contenga il campo di spezzamento δ^*. La A risulta priva di autonullifici, mentre il luogo dei punti ξ di S_{n-1} rappresentativi dei nullifici di A è lo stesso n-simplesso di S_{n-1} la cui restrizione (allo S_{n-1} su γ) è il luogo delle varietà fondamentali della trasformazione cremoniana T. Gli n vertici di questo simplesso sono le immagini dei nullifici di indice $n-1$ di A. Infine (sempre se $\chi \supseteq \delta^*$) l'autore riesce a caratterizzare compiutamente la struttura di A provando che essa è somma diretta di n algebre del 1° ordine, ciascuna "isomorfa" al campo χ. L'autore passa poi a considerare il gruppo Γ di Galois del campo δ rispetto al campo γ, nell'ipotesi (verificata automaticamente, se δ è finito) che sia $\delta = \delta^*$, ossia che l'estensione da γ a δ sia anche normale. Infine l'autore si occupa degli elementi di una estensione algebrica aventi norma assegnata c. Nel caso che il campo δ sia finito e l'ordine del suo sottocampo γ sia $q = p^h$, la norma c può essere un qualsiasi elemento non nullo di γ ed il numero degli elementi aventi quella norma (che si ottengono tutti da uno di essi con le trasformazioni del gruppo di Galois di δ rispetto a γ) è sempre uguale a $(q^n - 1)/(q - 1)$.

Nella 2ª parte della memoria l'autore si occupa dapprima delle fibrazioni (globali) mediante sottospazi S_{n-1} di uno spazio grafico irriducibile S_{s-1} $(1 < n < s)$. Nel caso che l'S_{s-1} sia finito la condizione che n divida s, cioè che sia $s = n \cdot r$, è necessaria e sufficiente per l'esistenza di una fibrazione siffatta. La stessa condizione è anche sufficiente, nel caso che lo spazio S_{s-1} sia lineare sopra un campo γ qualsiasi, supposto che esista un'algebra A su γ, primitiva, di ordine n e, se $r \neq 2$, anche associativa. Questo è appunto il caso che si presenta quando S_{s-1} è uno spazio grafico pascaliano, ossia lineare sopra un campo γ ed A è l'algebra relativa all'estensione (algebrica, separabile e di ordine $n \geq 2$) del campo γ ad un suo sovracampo δ. Si riesce allora a costruire (su γ) un "sistema grafico elementare" Σ di spazi S_{n-1} fibranti. Un sistema grafico elementare siffatto definisce in S_{s-1} una n-pla di sottospazi "direttori" S_{r-1}, linearmente indipendenti (e coniugati nella estensione da γ a δ^*), ed è costituito da quei sottospazi S_{n-1} di S_{s-1} che son definiti su γ e si appoggiano in un sol punto a ciascuno degli n spazi direttori S_{r-1}. Il sistema Σ costituisce un primo "modello" algebrico dell'S_{r-1} che si ottiene da uno spazio S'_{r-1} lineare su γ quando dal campo base iniziale γ si passa alla sua estensione algebrica δ. Un tale modello, interamente definito su γ, è utile per descrivere la geometria algebrica di S_{r-1} senza uscire dal campo γ iniziale, quando δ sia la chiusura algebrica di γ. Un secondo modello è fornito dalla immagine W di Σ sulla grassmanniana rappresentativa degli S_{n-1} di S_{s-1}. La W è una varietà di C. Segre (prodotto degli n spazi direttori del sistema grafico Σ), appartenente ad uno spazio S_{r^n-1} lineare su γ, della quale si conoscono anche l'ordine e la dimensione.

L'autore considera poi sui modelli Σ e W le immagini (definite in γ) G/G_0 e rispettivamente G' del gruppo delle omografie (definite in δ) dell' S_{r-1} in sè. Inoltre, su W, considera le sottovarietà immagini degli spazi subordinati all' S_{r-1} e le sottovarietà (di Veronese, generalizzate) immagini della totalità delle forme di ordine n di uno di quegli spazi. Il gruppo G consta di tutte e sole le omografie (su γ) di S_{s-1} che mutano in sè Σ, lasciando fisso ciascuno dei suoi spazi direttori. Il gruppo G' consta di tutte e sole le omografie (su γ) dell'ambiente che mutano in sè la W, lasciando fisso ciascuno dei suoi n sistemi di generatori. G_0 è il nucleo dell'omomorfismo che intercede tra G e G' ed è isomorfo al gruppo delle omografie che mutano in sè un S_{n-1} di Σ lasciando fissi i suoi n punti d'appoggio con gli spazi direttori. Tanto G quanto G' sono sottogruppi invarianti rispettivamente del gruppo $\bar{G}$ di tutte le omografie (su γ) di S_{s-1} che trasformano in sè Σ e del gruppo $\bar{G}'$ di tutte le omografie dell'ambiente (su γ) che trasformano in sè W. I due gruppi quozienti $\bar{G}/G$ e $\bar{G}'/G'$ risultano isomorfi tra loro ed al gruppo Γ di Galois di δ rispetto a γ. Si ottengono così delle rappresentazioni geometriche di Γ che consentono di studiarne sinteticamente la struttura.

Un terzo modello (definito su γ), dell' S_r che si ottiene da uno spazio S_r' lineare su γ quando il campo γ si amplia in quello δ, si ottiene partendo da una base $u_1, \cdots, u_n$ dell'ampliamento e considerando le coordinate proiettive non omogenee $\xi_i = x_{i1}u_1 + \cdots + x_{in}u_n$ $(i = 1, \cdots, r)$ di un punto dell' S_r. Allora, essendo $s = n \cdot r$, la s-pla di elementi x_{ij} si può interpretare come quella delle coordinate proiettive non omogenee di un punto di un S_s lineare su γ, cosicchè i punti propri dello S_r vengono a rappresentarsi coi punti propri dello S_s. D'altra parte le stesse ξ_i possono interpretarsi come coordinate proiettive omogenee di un punto dell' S_{r-1} improprio del riferimento di S_r, e per questo S_{r-1} (su δ) si può considerare un modello del primo tipo (definito su γ), rappresentandone biunivocamente i punti sugli spazi fibranti di un sistema grafico elementare di S_{n-1} appartenente all' S_{s-1} improprio dell' S_s già considerato. Questo terzo modello si può anche ottenere dal secondo mediante una "proiezione stereografica".

La 3ª parte della memoria inizia con la più generale definizione dei "sistemi grafici" $\Sigma_{n,r}$ di sottospazi S_{n-1} fibranti uno spazio grafico irriducibile S_{s-1}, con $s = n \cdot r$ ed $r, n > 1$. Di questi $\Sigma_{n,r}$ sono casi particolari i sistemi grafici "elementari", già considerati nella 2ª parte. Ogni $\Sigma_{n,r}$ si può pensare a sua volta come uno spazio grafico

astratto irriducibile R_{r-1}, di cui sono "punti" gli S_{s-1} del sistema. Questo R_{r-1} si può sempre immergere in un R_r, procedendo in modo analogo a quello tenuto nella costruzione dei modelli del 3° tipo considerati nella 2ª parte della Memoria. Per $r>2$ tanto lo S_{s-1} quanto lo R_{r-1} risultano desarguesiani, ossia lineari rispettivamente sopra dei corpi γ e $\delta\supset\gamma$, che risultano definiti a meno d'isomorfismi. La costruzione sintetica delle coordinate fa vedere che δ è una estensione di rango n di γ. L'autore si occupa poi dei casi in cui dapprima solo γ, e poi anche δ risultano commutativi, illustrando anche i collegamenti dell'argomento con la teoria delle algebre associative e primitive sopra un corpo γ.

Un sistema grafico $\Sigma_{n,r}$ di un S_{s-1} definito su di un campo γ si dice "generale" se—entro un S_{2n-1} di S_{s-1}—possono trovarsi quattro distinti S_{n-1} di Σ che ammettano n distinte rette trasversali comuni (definite in γ od in una sua estensione). Risulta allora che i soli sistemi grafici che siano pascaliani (cioè tali che δ sia commutativo) e generali sono quelli elementari. Nel caso che γ sia un campo finito, ossia in un S_{s-1} di Galois, possono aversi sistemi grafici $\Sigma_{n,r}$ generali che non siano elementari soltanto nel caso che risulti $r=2$, $s=2n$. Anzi, in un S_{2n-1} di Galois, un $\Sigma_{n,2}$ generale, ma non elementare, risulta certamente non desarguesiano (cioè non è desarguesiano il piano R_2). Lo stesso accade in un S_3 reale per ogni sistema grafico $\Sigma_{2,2}$ di rette che sia generale ma non elementare. Da ciò deriva un metodo per la costruzione di piani grafici R non desarguesiani, finiti o reali. Anche per precisare la portata di questo metodo, l'autore affronta e risolve il problema della determinazione e classificazione dei sistemi grafici $\Sigma_{n,2}$ e $\Sigma_{2,2}$ suddetti. Così nel § 10 vengono determinate e classificate le fibrazioni mediante rette di uno spazio tridimensionale S_3 sopra un campo γ e si forniscono due esempi di piani grafici finiti non desarguesiani, di ordini rispettivi 9 e 25. Nel § 11 l'autore si occupa delle fibrazioni di un S_{2n-1} di Galois mediante S_{n-1}. Nell'ipotesi sia valida la congettura (vera per $n=2, 3, 4$) che esista qualche collineazione non omografica di un S_{n-1} lineare su γ la quale sia priva di spazi uniti, l'autore dimostra l'esistenza di fibrazioni, ossia di sistemi grafici $\Sigma_{n,r}$ non elementari. Così ottiene dei piani grafici finiti non desarguesiani di ordine p^k, con p primo e k non primo.

Infine l'autore segnala alcuni problemi ancora da risolvere, sulla geometrizzazione delle estensioni algebriche, sulle fibrazioni proiettive, sugli elementi uniti delle collineazioni di uno spazio pascaliano, sulla classificazione dei piani grafici non desarguesiani ottenibili con i metodi indicati sopra e sul loro confronto con quelli già noti.

Projective metrics. (Russian)

Uspehi Mat. Nauk **19** (1964), no. 5 (119), 51–113.

This is a very useful and well-written survey of our present state of knowledge regarding the Cayley-Klein metrics in n-dimensional real projective space P^n.

Since the subject is little known, but interesting, it seemed best for the purposes of this review to define the spaces precisely and then outline briefly the topics treated in the paper.

The classical non-euclidean geometries arise from an absolute locus $a_{ik}x^ix^k = 0$ $(a_{ik} = a_{ki})$ with $\det(a_{ik}) \neq 0$ $(i, k = 0, \cdots, n)$. If j $(0 \leq j < n)$ is the index of this quadratic form, then ${}^jS_n$ is the corresponding space, in particular, ${}^0S_n$ and ${}^1S_n$ are the ordinary elliptic and hyperbolic spaces. If the rank of (a_{ik}) is $r+1 < n+1$, then $a_{ik}x^ix^k = 0$ represents a quadratic cone. If the form has index j, then the cone has $(n-r+j-1)$-dimensional generators and an $(n-r-1)$-dimensional "apex plane".

The semi-non-euclidean space ${}^{l_0 \cdots l_r}S_n^{m_0 \cdots m_{r-1}}$ is the P^n with an absolute locus of the following type: first we have a quadratic cone Q_0 of index j_0 with an $(n-m_0-1)$-dimensional apex plane T_0, then in T_0 a quadratic cone Q_1 of index j_1 with an apex plane T_1 of dimension $n-m_1-1$, $\cdots$, finally in the apex plane T_r-1 of Q_r-1 a non-degenerate quadric Q_r of index j_r. If all $j_i = 0$ we obtain a semi-elliptic space. If $m_0 = 0$ we delete the points of T_0 from the space and get the semi-euclidean space ${}^{l_1 \cdots l_r}R_n^{m_1 \cdots m_{r-1}}$. For $r=1$, $m_0 = 0$ we have the euclidean space ${}^jR_n$, where the absolute locus consists of a pair of hyperplanes coinciding with the hyperplane at infinity and in this hyperplane a non-degenerate quadric of index j. For $j=0$ we get the ordinary euclidean space, ${}^1R_4$ is the Lorentz space; ${}^{0 \cdots 0}R^{12 \cdots n-1}$ is the flag space, where the absolute consists of a set of r-planes $(r = 0, 1, \cdots, n-1)$, each contained in the next. It is shown that the semi-non-euclidean and semi-euclidean spaces can be obtained from the ${}^jS_n$ or ${}^jR_n$ by limit processes.

A line is non-euclidean of the ath order if it lies in T_{a-1} and intersects Q_a in two points. It carries a natural elliptic or hyperbolic metric δ_a with space constant 1 according to whether these points are conjugate, imaginary, or real. A line is euclidean of order a with a natural distance d_a if it intersects T_a but not T_{a+1}.

Angles between lines are defined by means of elliptic, parabolic or hyperbolic metrics in plane pencils of lines. One obtains in this way 3^2 geometries in P^2, and generally 3^n metrics in P^n.

The first topic is spheres, i.e., loci equidistant from a point. In particular, ${}^{l_1 \cdots l_r}S_n^{m_1 \cdots m_{r-1}}$ is isometric to the sphere of radius 1 in ${}^{l_1 \cdots l_r}R_{n+1}^{m_1 \cdots m_{r-1}}$.

Motions are defined as collineations which take the absolute into itself and preserve the distances d_a (they automatically preserve the δ_a). For $m_0 \neq 0$, i.e., in the case of semi-non-euclidean spaces, it suffices to require that the δ_a and d_a are preserved. The structures of the groups of motions are involved, and there are open problems, but they all have dimension $n(n+1)/2$.

The paper then turns to hyperplanes, questions of duality and angles between hyperplanes, next to lower-dimensional planes, in particular, covariants and invariants of pairs of planes. As is well known, one "angle" is, in general, not sufficient to determine the relative position of two lower-dimensional planes even in ordinary space ${}^0R_n$. The theory is, of course, much more complicated in the more general cases.

Cycles, i.e., hypersurfaces which in the above-mentioned isometric representation of ${}^{l_1 \cdots l_r}S_n^{m_1 \cdots m_{r-1}}$ as unit sphere in ${}^{l_1 \cdots l_r}R_{n+1}^{m_1 \cdots m_{r-1}}$ appear as intersections of this sphere with hyperplanes, are discussed next. In analogy to stereographic projection, this leads in a natural way to a definition of conformal maps, in particular, to inversions as involutoric conformal maps.

The last chapter deals with relations to algebra which arise by introducing numbers $x+\varepsilon y$ $(\varepsilon^2 = -1, \varepsilon^2 = 0, \varepsilon^2 = 1)$ and the corresponding bicomplex numbers or quaternions and biquaternions. Analogues of the Gauss plane, the Riemann sphere and the Poincaré upper half-plane provide models for the different two-dimensional geometries, for example, the Gauss plane with $\varepsilon^2 = 0$ yields the flag space ${}^0R_2{}^1$ and with $\varepsilon^2 = 1$ it yields ${}^1R_2$. The extension of the usual applications of these numbers to line geometry in the three-dimensional spaces and certain four- and five-dimensional geometries are discussed. A general algebraic scheme for all dimensions is outlined in the concluding section.

Burniat, Pol 6378

Variétés algébriques V_3 à surfaces canoniques unies dans une involution d'ordre 3.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 77–89.

S^0 is the algebraic threefold with rational function field defined by adjoining $\sqrt[3]{E}$ to that of three-dimensional projective space S, where $E=0$ is an irreducible member of a trisectable linear system $|E|=|3e|$, defined as complete with respect to certain base conditions. The canonical system on S^0 is the image of the system in S adjoint to $|2e|$. S^0 is shown to be regular, and its canonical and all pluricanonical systems irreducible, in the following two cases:

(i) $|e|$ of order $r+2$, with an r-ple base line and $q \leq 2r+2$ simple base points each with a simple base line in its neighbourhood (i.e., with fixed tangent plane). $P_g = P_a = 6r+1-q$.

(ii) $|e|$ of order $r+2$ with an r-ple base line a, a simple base line b skew to a, and $q \leq 2r+2$ further simple base lines meeting a and b. $P_g = P_a = 4r-q$.

Further, if e is of order $2r+1$, with a skew quadrilateral of r-ple base lines, S^0 is regular with $P_g = P_a = 2r$, the canonical and all pluricanonical systems being compounded with the pencil of images of quadrics containing the quadrilateral; these surfaces have all genera equal to 1. If a further simple base line (meeting two opposite sides of the quadrilateral) is imposed on e, one surface of the pencil, image of the quadric through this additional base line, becomes a fixed part of the canonical system, so that $P_g = P_a = 2r-1$. *P. Demaria, Davide Carlo 6379

Sopra una proprietà delle varietà superficialmente regolari.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 341–352.

In previous work the author has obtained conditions under which, on a non-singular algebraic variety V_d, a complete linear system $|T|$ of hypersurfaces cuts a complete linear system on a given non-singular hypersurface S. In the present work the author considers the case in which V_d is superficially regular. He proves that if the system $|S-T|$ contains an effective non-singular hypersurface, then the system cut by $|T|$ on S is complete.

He further proves that a non-singular hypersurface D of a totally regular variety V_d is itself totally regular if and only if the divisor $-D$ has all its indices of irregularity equal to zero. *L. Roth* (London)

Godeaux, Lucien 6380

Sur les surfaces représentant les couples de points de certaines courbes algébriques.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 61–68.

Se L è una curva algebrica non iperellittica che contenga una involuzione γ del second'ordine priva di coincidenze, si considera la superficie F che rappresenta le coppie non ordinate di punti di L; essa possiede una involuzione del secondo ordine avente una curva unita, e la superficie Φ immagine di questa involuzione è anch'essa sostegno di una involuzione del secondo ordine, priva di coincidenze. Detta F' l'immagine di questa involuzione, F' risulta la superficie che rappresenta le coppie non ordinate di punti della curva immagine di γ. F' e Φ hanno la stessa irregolarità. *D. Tallini, Giuseppe

Calotte complete di $S_{4,q}$ contenenti due qua ellittiche quali sezioni iperpiane.

Rend. Mat. e Appl. (5) **23** (1964), 108–123.

In a Galois space $S_{r,q}$ (i.e., a projective r-dimensional over a $GF(q)$) a k-cap (k-arc if $r=2$) is a set of k poi three of which are on a line; moreover, a k-cap is s be complete when there is no $(k+1)$-cap containi While the theory of caps is well developed for r [cf. B. Segre, Ann. Mat. Pura Appl. (4) 48 (1959), MR 22 #7054; Acta Arith. 5 (1959), 315–332; M #4980; *Lectures on modern geometry*, Edizioni Crem Rome, 1961; MR 24 #A1045], very little is known it for $r \geq 4$.

The present author determines all the complete of $S_{4,q}$ which are cut along (non-ruled) quadric su by two distinct primes, S' and S'', of $S_{4,q}$. Several arise, according to the parity of q and the possible in which the two quadrics are intersected by the $S' \cap S''$. Thus the existence is proved of complete of $S_{4,q}$ satisfying the condition above, where k take following values: $2q^2+q+5$ (q even and >2), $2q$ $2q^2+1$ (q odd), $2q^2+2q+1$ (q odd and >3), 2 (q even and >2). *B. For $n = p^{2m} + p^m + 1$ (p prime) a set of n points and one of n lines is given; two lines have at most one point in common. The author proves by means of the properties of an incidence matrix that for the number N of incidences of a point and a line the inequality $N \leq N_0 = n/p^m + 1$ holds. For $N = N_0$ the system is a finite projective geometry. *O. Bottema* (Delft)

d'Orgeval, B. 6386

A propos des courbes d'ordre $q+2$ qui contiennent tous les points d'un plan de Galois $S_{2,q}$.

Bull. Soc. Roy. Sci. Liège **33** (1964), 264–269.

Dans un plan de Galois $S_{2,q}$, entre les courbes irréductibles qui contiennent tous les points d'un $S_{2,q}$, celles d'ordre minimum sont des C_{q+2}, qui ont été introduites, étudiées et classifiées du point de vue projectif par le rapporteur [Rend. Mat. e Appl. (5) **20** (1961), 431–479; MR **25** #4413]. Chaque point de $S_{2,q}$ est simple pour une telle C_{q+2}; il y a donc une correspondance biunivoque entre les points et les droites de $S_{2,q}$ si l'on associe à chaque point de $S_{2,q}$ la tangente à C_{q+2} en ce point. Par dualité, dite C^{q+2} une enveloppe irréductible d'ordre minimum $q+2$ contenant toutes les droites de $S_{2,q}$, elle détermine une correspondance biunivoque entre les droites et les points de $S_{2,q}$ si l'on associe à chaque droite son point caractéristique (c'est-à-dire la notion duale de droite tangente en un point). L'auteur démontre que chaque C_{q+2} détermine de façon biunivoque une C^{q+2} telle que, pour chaque droite r de $S_{2,q}$, le point caractéristique coïncide avec le point de contact de r avec C^{q+2}. Il démontre aussi que la C^{q+2} est équivalente, à une corrélation près, à la courbe C_{q+2}. Après avoir fixé une polarité (qui néanmoins n'est pas intrinsèquement liée à la courbe C_{q+2}) et avoir dénoté par C'_{q+2} la courbe transformée de C^{q+2} par rapport à cette polarité, l'auteur examine la question de déterminer quand la relation entre C_{q+2} et C'_{q+2} est involutive.

Kosmák, Ladislav 6390

A remark on Helly's theorem. (Czech. Russian and English summaries)

Spisy Přírod. Fak. Univ. Brno **1963**, 223–225.

The following statement is often called "Radon's theorem": "If V is a subset of affine n-space containing $n+2$ points, there exist sets $V_1, V_2 \subset V$ such that $V_1 \cap V_2 = \varnothing$ but $\operatorname{conv} V_1 \cap \operatorname{conv} V_2 \neq \varnothing$ (where $\operatorname{conv} A$ denotes the convex hull of A). The subsets V_i of V are uniquely determined if and only if every $n+1$ points of V are affinely independent" [R. Rado, J. London Math. Soc. **27** (1952), 320–328; MR **13**, 970; I. V. Proskurjakov, Uspehi Mat. Nauk **14** (1959), no. 1 (85), 219–222; MR **20** #6681]. In the present paper a new proof is given for the following addendum to Radon's theorem (first established by Proskurjakov, loc. cit.): If every $n+1$ points of V are affinely independent, two points of V belong to the same V_i if and only if they are separated by the $(n-1)$-dimensional affine variety determined by the remaining n points of V.

{Reviewer's remark: It is much easier to establish Proskurjakov's result algebraically. If $V = \{v_0, \cdots, v_{n+1}\}$, there exist reals $\alpha_0, \cdots, \alpha_{n+1}$, not all 0, such that $\sum \alpha_i = 0$, $\sum \alpha_i v_i = 0$. In case of unique V_i's the α_i's are determined up to a constant factor, and v_i's having α_i's of the same sign belong to the same V_i. Now, if $\{x \mid (x; u) = \beta\}$ is a hyperplane containing all points of V except v_j and v_k, then $\alpha_j[(v_j; u) - \beta] + \alpha_k[(v_k; u) - \beta] = 0$, which implies Proskurjakov's result.} *B. Grünbaum* (Jerusalem)

Ceder, Jack G. 6391

A property of planar convex bodies.

Israel J. Math. 1 (1963), 248–253.

The author proves that for every closed convex curve C in the plane and for any point O in the interior of C there exist points A_1, A_2, A_3 of C such that the vectors $\overrightarrow{OA_1}+\overrightarrow{OA_2}$, $\overrightarrow{OA_2}+\overrightarrow{OA_3}$, $\overrightarrow{OA_3}+\overrightarrow{OA_1}$ have terminal points on C. The six points thus determined on C are the vertices of a centrally symmetric hexagon inscribed in C. Denoting by V the set of all points of C which are vertices of such inscribed hexagons, the author shows that the complement N of V in C consists of isolated points provided C is rotund and smooth. The vertices of a triangle show that, for general C, $N\neq\varnothing$ is possible. As open problems the author mentions: (1) Is $V=C$ for rotund and smooth C? (2) Is N countable for all C?

{Reviewer's remark. The answer to (1) is affirmative. Simple continuity arguments show that, for smooth and rotund C, among all parallelograms inscribed into C and having a given point of C as vertex, there are at least two different parallelograms with coinciding centers. Their vertices determine a centrally symmetric hexagon inscribed in C, which has the given point as one of the vertices.} *B. Grünbaum* (Jerusalem)

Rényi, A.; Sulanke, R. 6392

Über die konvexe Hülle von n zufällig gewählten Punkten. II.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete 2, 138–147 (1964).

If K is a bounded convex set in the plane and P_i, $1\leq i\leq n$, are n points in K chosen independently and with uniform distribution in K, the authors denote the convex hull of the n points by H_n. In a previous note [same Z. 2 (1963), 75–84; MR 27 #6190] the authors considered the number of sides in the polygon making up the boundary of H_n. In the present note they consider the area F_n of H_n and the length L_n of the boundary of H_n. It is clear that F_n and L_n are random variables whose expectations $E(F_n)$, $E(L_n)$ approach, as $n\to\infty$, the area F and length of the boundary L of the set K. They investigate the behaviour of the differences $F-E(F_n)$ and $L-E(L_n)$ as $n\to\infty$. Different asymptotic formulae are derived for two cases: (a) K has a continuously differentiable boundary with a bounded curvature; (b) K is a square.

Bleicher, M. N.; Fejes Tóth, L. 6393

Circle-packings and circle-coverings on a cylinder.

Michigan Math. J. 11 (1964), 337–341.

It has long been known that the closest packing and thinnest covering of the whole Euclidean plane by equal circles are provided by the incircles and circumcircles (respectively) of the hexagons in the regular tessellation {6, 3}. The authors consider how these arrangements have to be modified when the whole plane is replaced by the strip between two parallel lines, with orthogonally corresponding points on them identified. If the distance between the lines is p times the common radius of the circles, the regular arrangement will, in general, conflict with this identification, and some modification will be required. The authors have determined the cases when this necessary modification is most drastic. The con-clusions are as follows. The maximal packing dens… at least $\pi/4$, and this minimum is attained when $p=$… the minimal covering density is at most $\pi/2$, and… maximum is attained when $p=2$.

★**Classical differential geometry in tensor form [К…сическая дифференциальная геометрия в тензор… изложении].**

Edited by A. P. Norden.

Gosudarstv. Izdat. Fiz.-Mat. Lit., Moscow, 1… 540 pp. 1.44 r.

This book differs somewhat from the ordinary "clas… differential geometry" in so far as it is based on the th… of curve nets and congruences, which are analysed… the aid of vector and tensor fields. This is an approac… which the author, professor in Kazan, has himself… tributed in several papers. He has divided the book…

a part on two-dimensional and another part on three-dimensional space. The first chapter of the first part begins immediately with vector fields and nets on an X_2, where X_2 is a two-dimensional manifold, where the bivectors ε_{ij}, $i, j, s = 1, 2$; $\varepsilon_{12} = \varepsilon$ and ε^{ij}, $\varepsilon^{12} = 1/\varepsilon$ serve to pass from covariant to contravariant: $T_k\varepsilon^{sk} = T^s$, $T^s\varepsilon_{ks} = T_k$. A set of curves is then defined by $a_{ks}x^k x^s = 0$. Among the important concepts here is that of apolar nets a_{ks}, b_{ks} if $a^{ks}b_{ks} = 0$. The theory is then applied to Riemannian V_2 and affine A_2 (geodesic lines, curvature tensor, etc.) with special chapters on diagonal nets and other special nets. Among them are isothermal nets on V_2, in which $ds^2 = e^{-2\sigma}(du^2 + dv^2)$; if $e^{-2\sigma} = [U(u) + V(v)]^m$, then we have L_m-nets. Dubnov nets on an A_2 are such that their Čebyšev vector a_i satisfies the equation $a_{(i|s)} - a_i a_s = R_{(is)}$, where $R_{(is)}$ is the Ricci tensor. When $a_i = 0$ we have Čebyšev nets. There is a chapter on Lie groups and automorphisms of surfaces, and the chapter ends with so-called Π-families of nets, which are manifolds of nets with the same apolar net and equal Čebyšev vector.

The second part of the book is called "Surfaces and congruences of three-dimensional space" and begins with a fairly "classical" surface theory (in tensor form), though already here we meet the formulas of Lelieuvre and Moutard. A chapter is devoted to special classes of surfaces; among them are rotation, spiral, ruled, translation, minimal, evolute and W-surfaces, surfaces of Voss, and cyclides, with several aspects of these surfaces usually not found in other books. Then follows a chapter on line congruences, again with several special examples, and a chapter on congruences of spheres and circles. The book ends with infinitesimal bending and W-congruences, to which are added some special bendings of surfaces.

The material, thus presented from a central point of view, is based, to a great extent, on the work of Russian authors (Blank, Dubnov, Efimov, Finikov, Liber, Norden, Čahtauri, among others).

The book can be especially recommended to those who have to teach a course in "classical" differential geometry, and want a change in subject matter from the customary program.

The book, writes the author, has been written for scientific workers, aspirants and students of advanced courses in the universities and "pedinstitutes", who specialize in geometry. *D. J. Struik* (Belmont, Mass.)

Upadhyay, M. D. 6397

Director surfaces with orthogonal correspondence.

Tensor (*N.S.*) 15 (1964), 228–232.

Let S be the surface of reference of a congruence. A family of curves on S together with the lines of the congruence determines a family of ruled surfaces of the congruence, which in turn defines a family of lines of striction forming a surface $\bar{S}$. It seems that the author intends to find a condition for orthogonality between corresponding curves at corresponding points x^i on S and y^i on $\bar{S}$. The equation of $\bar{S}$ is given by (1.1): $y^i = x^i + t\lambda^i$, where t represents the distance from x^i to the central point y^i on the line of the congruence passing through x^i with direction cosines λ^i. It is evident that in general t is not a constant. Hence equation (3.2) $y^i{}_{,\alpha} = x^i{}_{,\alpha} + t\lambda^i{}_{,\alpha}$, cannot be obtained from (1.1). Since (3.2) plays an important role and is wrong, the paper needs revision.

Infinitesimal bendings of piecewise regular surfaces of revolution of negative curvature. (Russian)

Ukrain. Mat. Ž. 14 (1962), 422–426.

The author extends results proved by him previously for smooth surfaces of revolution [same Ž. 14 (1962), 18–29; MR 26 #4298] to surfaces of revolution $r = f(z)$ $(\alpha \leq z \leq \beta)$ of negative curvature, where $f(z)$ is piecewise of class C^3. The bending field is assumed to be continuous and of class C^2 where the surface is of class C^3. The results are the following. For each z_0 there is a countable dense set of z_1 such that the zone from z_0 to z_1 is not rigid. There is a countable dense set of $h_1 > 0$ such that the surface $r + h_1 = f(z)$ $(\alpha \leq z < \beta)$ is not rigid.

Sur les déformations équivalentes infinitésimales des surfaces.

Univ. Nac. Tucumán Rev. Ser. A 14 (1962), 177–188.

Cet article est consacré à l'étude des transformations infinitésimales équivalentes des surfaces (transformations infinitésimales qui conservent les aires). Pour ce faire, on considère des congruences rectilignes dont les rayons portent les directions des déplacements infinitésimaux des différents points de la surface S envisagée. Le cas où ces déplacements infinitésimaux sont tangents à S (auto-transformations) est pris en considération quelle que soit S. Dans une transformation infinitésimale équivalente, le champ des déplacements ne peut être normal à S, à moins que cette dernière soit minima. En vue de donner une idée sur ce qui a été obtenu par l'auteur, citons en particulier ce qui suit: Dans le cas où S est une sphère de centre O, la déformation infinitésimale équivalente la plus générale de S est fournie par la donnée d'une congruence rectiligne quelconque, dont la représentation sphérique est faite sur S. Si par le point représentatif M d'un rayon D, on mène le vecteur équipollent à $\overrightarrow{OI}$, I étant le milieu du segment focal de D, le déplacement infinitésimal de M est donné par $\delta\overrightarrow{M} = \varepsilon \cdot \overrightarrow{OI}$, où ε est une constante infinitésimale, dont les puissances supérieures à la première sont négligées. Pour les auto-transformations équivalentes de la sphère, l'enveloppée moyenne des congruences rectilignes (D) est le point fixe O. L'article se termine par l'application des transformations infinitésimales équivalentes aux surfaces harmoniques. *F. Şemin* (Istanbul)

★Geometry of manifolds.

Pure and Applied Mathematics, Vol. XV.

Academic Press, New York-London, 1964. ix + 273 pp. $10.50.

This book represents an excellent treatment of a wide section of modern differential geometry. As the authors acknowledge in the preface it owes much to the distinguished school of differential geometry at M.I.T. and,

in particular, to W. Ambrose and I. Singer, who in turn draw upon the pioneering work of Cartan, Chern, and Ehresmann. The style is elegant and at the same time considerate for the needs of a beginner. Many comments are given to related questions as well as a great number of well chosen problems with pertinent references whenever desirable. This makes it possible to cover in considerable detail the foundations of the field as there are Manifolds, Lie groups, Fibre bundles, Differential forms, Connexions, Affine connexions, Riemannian manifolds. The last 113 pages of the 257-page text are devoted to a study of the global structure of Riemannian manifolds: Geodesics and complete Riemannian manifolds, Riemannian curvature, Immersions and second fundamental form, Second variation of arc length. In this part, in particular, there are many subjects which appear for the first time in a textbook or even anywhere else. The authors seem to have been quite successful in avoiding serious errors without doing it the easy way by glossing over the details. In summa, the reviewer thinks that anybody who chooses to base his course on differential geometry at the graduate level on this book could not do better. *W. Klingenberg* (Mainz)

Hahn, Kyong T. 6402

Minimum problems of Plateau type in the Bergman metric space.

Pacific J. Math. 14 (1964), 943–955.

Let D be a bounded domain in the space C^n of n complex variables, let K_D be the Bergman kernel and ds_D the Bergman metric, $ds_D{}^2(z) = K_D(z, \bar{z})|dz|^2$, invariant under pseudo-conformal mappings. Then D can be metrized by d, where d is the geodesic distance determined by ds_D. Let $Q_0 = [0, 1] \times [0, 1]$. If $G: Q_0 \to C^2$ is piecewise of class C', then the invariant B-area of the surface S described by G is $B_D(S) = \iint_{Q_0} [K_D(G, \bar{G})]^{1/2} |\partial(G_1, G_2)/\partial(u_1, u_2)| \, du dv$. If Γ is a simple closed curve in D and if C' is the class of surfaces bounded by Γ each of which is given by a representation which, together with its derivative, is Lipschitzian, then C' contains a surface of minimal area if C' is not empty. If $n = 1$ and D is bounded by simple closed curves $b_1, \cdots, b_n$, where b_n is the outer boundary component, then there exists a curve of smallest length in D which is homotopic to b_1. There are also distortion theorems for both length and area and results concerning minimal closed surfaces. *E. Silverman* (Lafayette, Ind.)

**Congruences of second-order curves with undeterm
focal families.** (Russian)

Trudy Tomsk. Gos. Univ. Ser. Meh.-Mat. Geom
160 (1962), 5–14.

The starting point is the general theory of congru
of second order in projective three-space given by S
Tuganov [Dokl. Akad. Nauk SSSR 100 (1955), 1
MR 16, 1050]. In the present paper the special ca
studied in which two contiguous curves of the
gruence intersect each other under arbitrary disp
ment in two different or coinciding points. For
congruences, named C_0, the foci of the conics and
focal families are not determined, so that Tuga
canonical reference system becomes illusory and
necessary to construct a new canonical reference sy
It is shown how this can be done, and how such a sy
can be geometrically characterized. Among the theo
that hold for congruences C_0 we mention that a C_0
two families of principal focal lines and two prin
focal surfaces; if these do not coincide, the congruen
determined by an arbitrary function of two vari
(focal points are the points of intersection of two
tiguous conics). An example of a congruence C
euclidean space is the congruence of great circles
sphere. Two special types of congruences C_0 are
investigated. *D. J. Struik* (Belmont, M

Manifolds of algebraic elements in an n-dimensional projective space. (Russian)

Trudy Tomsk. Gos. Univ. Ser. Meh.-Mat. **168** (1963), 28–42.

An $(n-2)$-dimensional non-degenerate hypersurface of degree k (k even and positive) of the hyperplane P_{n-1} of the n-dimensional projective space P_n is said to be an algebraic element A^k_{n-2}. Let $(h, m, n)^k$ denote an m-dimensional manifold of the algebraic elements $A^k_{n-2} \subset P_n$, the set of all hyperplanes of P_n containing algebraic elements of the given manifold being h-parametric ($h \leq m$, $h \leq n$, $1 \leq m < C^n_{n+k-1} + n - 1$, $n \geq 3$).

The projective differential geometry of the manifolds $(h, h, n)^k$ and $(n, n, n)^k$ is developed. Special theorems concerning the manifolds $(n, n, n)^2$ are obtained.

Malahovskiĭ, V. S. 6410

Congruences of second-order curves whose planes form a one-parameter family. (Russian)

Trudy Tomsk. Gos. Univ. Ser. Meh.-Mat. **168** (1963), 61–65.

The present paper deals with congruences of conics in a three-dimensional projective space whose planes form a one-parameter family. The author studies the non-parabolic case (the characteristic lines of the planes of conics are not tangent to the conics of the congruence) under the following restrictive assumption. The intersecting points of the conic C of the congruence with the characteristic line of its plane are not conjugated with respect to the conic C^* determined by the four focal points of the conic C and the pole of the characteristic line with respect to the same conic C. The congruences under investigation are called T-congruences of conics.

Šul'man, T. A. 6411

Invariant nets on hypersurfaces in a four-dimensional projective space. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* 5 (42), 137–142.

The present paper deals with asymptotic and conjugate curves and nets of the first and second order on hypersurfaces in a four-dimensional projective space. By asymptotic and conjugate curves of the first order are meant the usual ones. Asymptotic [conjugate] curves of the second order are defined—if the conventional notation and choice of the moving coordinate frame is applied—by the conditions $(A_0A_1A_2A_3d^2A_0)=(A_0A_1A_2A_3d^3A_0)=0$ $[(A_0A_1A_2A_3d_2d_1A_0)=(A_0A_1A_2A_3d_3d_2d_1A_0)=0]$.

Ancochea, G. 6412

Sur la représentation des éléments différentiels de l'espace projectif.

Ann. Mat. Pura Appl. (4) **65** (1964), 341–359.

L'auteur présente un exposé d'ensemble de la représentation des éléments différentiels de l'espace projectif en la traitant dans le cadre de la théorie des espaces algébriques homogènes. Il donne d'abord la définition d'un élément différentiel de l'espace projectif $P(n, K)$ de dimension n sur le corps K en s'appuyant sur le concept de point proche introduit par A. Weil; la représentation des éléments différentiels se fait au moyen de variétés algébriques. Quelques exemples traités dans le cas du corps des réels permettent d'illustrer les particularités qui peuvent se présenter dans les cas généraux. L'auteur retrouve, simplement, tous les résultats déjà connus et il en établit de nouveaux, relatifs, en particulier, aux éléments d'ordre trois du plan et aux éléments superficiels d'ordre deux de l'espace à trois dimensions.

Bompiani, Enrico 6413

Reti e tritessuti di curve nel piano proiettivo.

Rend. Circ. Mat. Palermo (2) **12** (1963), 299–329.

L'auteur commence par montrer comment l'exposition de la théorie des réseaux plans, telle qu'elle a été faite par E. Čech au Chapitre X de l'ouvrage qu'il a rédigé en collaboration avec G. Fubini [*Introduction à la géométrie projective différentielle des surfaces*, Gauthier-Villars, Paris, 1931], et divers travaux récents s'y rapportant, gagnent à être présentés à la faveur de certaines de ses propres recherches [l'auteur, Atti Accad. Naz. Lincei Rend. (6) **22** (1935), 483–491; ibid. (6) **24** (1936), 323–332]. Non seulement la plupart des résultats connus reçoivent ainsi une exposition nouvelle, mais d'importants résultats inédits se trouvent établis, conférant au sujet étudié une ampleur de développement particulièrement suggestive. Dès le début l'introduction de la notion de courbure projective d'un E^2 (élément différentiel curviligne du 2e ordre) par rapport à un réseau plan conduit à la définition du système des courbes du plan à courbure projective nulle

relativement au réseau, et à la recherche des connexions symétriques conférant à ces dernières courbes le caractère auto-parallèle. Cette recherche conduit, en particulier, à un type de connexions complètement individualisées par le réseau envisagé, moyennant lesquelles peuvent être assignées les significations géométriques des coefficients des dérivées du 1^er ordre dans le système différentiel du 2^e ordre (mis sous forme normale) vérifié par les coordonnées homogènes du point courant du réseau. L'auteur reprend ensuite l'étude des correspondances entre deux plans π, $\bar\pi$. Il montre qu'étant donnée une transformation ponctuelle $\bar x = Tx$ de π en $\bar\pi$, il existe ∞^2 homographies Ω équivalentes à T quant à la transformation des voisinages du 1^er ordre des points x et $\bar x$, et que pour toutes ces homographies il existe trois pinceaux de E_2^2 (éléments curvilignes différentiels du 2^e ordre de centre x et de même tangente en x) tels que $TE_2^2 = \Omega E_2^2$, les tangentes aux trois pinceaux étant celles du 3-tissu caractéristique (dans π ou $\bar\pi$) de la correspondance. Il montre comment cette étude peut être approfondie et prolongée par celle de la correspondance entre les courbes de deux réseaux donnés dans π et $\bar\pi$, correspondance à laquelle est subordonnée une correspondance entre les plans (les ouverts) eux-mêmes. Si, indépendamment de toute correspondance entre π et $\bar\pi$, un réseau est donné dans π, divers 3-tissus peuvent lui être associés. Un premier procédé pour en obtenir consiste à normaliser les coordonnées projectives dans π, à considérer la correspondance entre π et un plan affine déduite de la normalisation, et à prendre les 3-tissus (dépendant de deux fonctions arbitraires d'un argument) caractéristiques de cette correspondance. Un autre procédé est basé sur la considération de la correspondance entre un voisinage d'un point x de π et son transformé dans une transformation de Laplace. Ce type de correspondance ne semble pas encore avoir été étudié; l'auteur pousse l'étude jusqu'aux voisinages du 2^e ordre, et introduit ainsi l'intéressante notion de 3-tissus $\mathscr{L}$-caractéristiques d'un réseau (définis par les transformés de Laplace du réseau et par suite intrinsèquement liés à ce dernier). Le mémoire se termine par la considération de certains invariants d'un réseau ou d'un 3-tissu, en relation avec la déformation projective du réseau ou du 3-tissu, et des significations géométriques sont données pour ces divers éléments. L'auteur montre en particulier que, pour un 3-tissu, il existe un invariant infinitésimal homogène, du 1^er ordre par rapport aux différentielles 1^ères, se présentant comme le rapport d'une forme quadratique et d'une forme (monôme) linéaire, et pouvant être pris comme définition de l'élément linéaire du 3-tissu.

Černylenko, V. M. 6414

Spaces with a special complex of geodesic curves. (Russian)

Trudy Sem. Vektor. Tenzor. Anal. **11** (1961), 253–268.

An affine manifold A_n is called almost-projective if it is possible to map it on a euclidean E_n in such a way that a complex of geodesic lines (i.e., a family of $2n-3$ parameters) remains geodesic. This complex is called the basic complex. This complex must either be linear or quadratic, i.e., the lines which pass through a point must either lie in a plane or form a quadratic cone (compare the author's paper [Naučn. Zap. Dnepropetrovsk. Univ. **55** (1961), 105–110]). In the first case the A_n is called of the first type, in the second case, of the second A necessary and sufficient condition that the A_n be second type is that there exists a coordinate systen that in it Γ^i_{jk} can be written

$$\Gamma^i_{jk} = \xi^i a_{jk} + \delta^i_j\varphi_k + \delta^i_k\varphi_j,$$

where $a_{jk} = a_{kj}$ determines the quadratic cone. Wh space is also Riemannian, $\partial g_{ij}/\partial u^k = \xi_i a_{jk} + \xi_j a_{ik} + 2$ $\varphi_i g_{jk} + \varphi_j g_{ik}$, where g_{ij} is the fundamental tensor, ξ_i For a_{ij} to be $= g_{ij}$ it is necessary and sufficient that be conformally euclidean. Conditions are derived f g_{ij} in the case that the basic complex is mapped complex of tangents to a non-degenerate quadric of t

Mihăilescu, Tiberiu

Problèmes variationnels projectifs dans la théori réseaux plans.

Bull. Sci. Math. (2) **86** (1962), 1ère partie, 5–48.

La première partie de ce mémoire contient la théor réseaux plans, développée par la méthode du mobile, de la manière selon laquelle l'auteur l'a appl dans le traité [*Projective differential geometry* (Roma Acad. R. P. Romîne, Bucharest, 1958; MR **22** #29 l'étude des surfaces et des réseaux. Il retrouve ain résultats connus et obtient des nouveaux résultats, su en ce qui concerne quelques classes de réseaux plans

On considère le repère mobile (A_0, A_1, A_2, I), de manière que le sommet A_0 décrive le réseau respectif les deux arêtes $[A_0, A_1]$, $[A_0, A_2]$ soient les tangente courbes t_1, t_2 du réseau. Les deux formes de Pfaff ω_0 sont linéairement indépendantes par rapport aux rentielles dt_1, dt_2, pouvant s'écrire

$$\omega_{12} = a_2\omega_{01} + a_2'\omega_{02},$$

$$\omega_{21} = b_2'\omega_{01} + b_2\omega_{02}.$$

La famille de ces repères (R_0) possède seulement

invariants infinitésimaux, qui sont des fonctions des deux invariants fondamentaux de Bompiani

$$\varphi_1 = \frac{a_2{\omega_{01}}^3}{\omega_{02}}, \qquad \varphi_2 = \frac{b_2{\omega_{02}}^3}{\omega_{01}}.$$

Moyennant ces deux invariants on définit ensuite les lignes de Darboux, les lignes de Segre, ainsi que les réseaux simplement réglés et les réseaux doublement réglés. A l'aide des deux transformés de Laplace A_1, A_2 du réseau A_0, on étudie certains couples de coniques et les réseaux de Königs, pour lesquels les deux coniques coïncident.

Dans la deuxième partie du mémoire sont envisagés des problèmes variationnels, concernant les réseaux plans et appartenant au type étudié dans le traité cité ci-dessus. On considère l'invariant infinitésimal

$$\Phi = \frac{\gamma_1{\varphi_1}^{2n+1} + \gamma_2{\varphi_2}^{2n+1}}{{\varphi_1}^n{\varphi_2}^n}$$

et puis l'intégrale à extrémités fixes $I = \int_{t_1}^{t_2} \Phi$.

Norden, A. P. 6417

Cartesian composition spaces. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1963**, no. 4 (35), 117–128.

Given r basic manifolds X_{n_a}, $a, b = 1, \cdots, r$, and in each of them a point M_a is selected. The composition of the X_{n_a} is such a space X_N whose points M are in 1-1 correspondence with all possible sets (M_a), $N = n_1 + n_2 + \cdots + n_r$. If all points of the set (M_a) except M_b are fixed, then the corresponding point M of X_N describes a submanifold of n_b dimensions in 1-1 correspondence with the basic X_{n_b}, and this submanifold is called the position of X_{n_b}. Two different positions of one basic manifold are called analogue, the positions of two different basic manifolds are called transversal; two analogue positions have no point in common, two transversal ones have a unique common point.

A system of curvilinear coordinates in the space of composition X_N is adapted with respect to the composition when it is defined by a system of curvilinear coordinates in every basic manifold. The place of a point in the position of an X_{n_a} determines n_a adapted coordinates u^i and $N - n_a$ adapted coordinates $u^{\bar{i}}$, called the internal and external coordinates with respect to the given position. The i and $\bar{i}$ are in opposition. The composition is called Cartesian if the tangent elements of an arbitrary family of analogue positions form a field of absolute parallelism. Then an arbitrary position will be an entirely geodesic X_N. Now a symmetrical connection $\Gamma^\gamma_{\alpha\beta}$, $\alpha, \beta, \gamma = 1, \cdots, N$, is introduced. A necessary and sufficient condition that a given composition is Cartesian is that the Γ vanish if and only if two indices are in opposition. An example is the composition of two X_1 to a set of X_2. If this set is Cartesian, then the position of the basic X_1 coincides with the isotropic lines of a Weyl space W_2 ($g_{11} = g_{22} = 0$, $g_{12} = 1$, $\nabla_\gamma g_{\alpha\beta} = 2\omega_\gamma g_{\alpha\beta}$, $\omega_1 = -\frac{1}{2}\Gamma^1_{11}$, $\omega_2 = -\frac{1}{2}\Gamma^2_{22}$). Another example is a Γ_{n+m}, allowing a Cartesian composition of an X_n and an X_m, with fully orthogonal position. Thus we can write $ds^2 = g_{ij}(u^k)du^i du^j + g_{\bar{i}\bar{j}}(u^{\bar{k}})du^{\bar{i}} du^{\bar{j}}$. It is also possible to apply these notions to surfaces and hypersurfaces in projective space. A special study is devoted to the autocomposition of a hyperquadric, which leads to tensors of the type of Širokov and Raševskiĭ [P. K. Raševskiĭ, Trudy Sem. Vektor. Tenzor. Anal. **6** (1948), 225–248; MR **15**, 62].

Sur les déformations infinitésimales projectives similaires des surfaces.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 353–367.

En prolongement d'un travail antérieur sur les translations projectives d'une surface en elle-même [Acad. R. P. Romîne Fil. Iaşi Stud. Cerc. Şti. Mat. **12** (1961), 69–94; MR **25** #505], l'auteur traite ici du problème de la recherche effective (effectuée sans doute pour la première fois) de surfaces admettant des déformations infinitésimales projectives similaires (p.s.), la similarité d'une correspondance projective entre deux surfaces étant caractérisée par la proportionnalité, avec rapport constant, des éléments linéaires projectifs de Fubini des deux surfaces. Les transformations simplement projectives d'une surface conservant les asymptotiques, l'auteur est naturellement conduit à envisager deux classes de surfaces admettant un groupe G_1 de déformations (p.s.) en elles-mêmes, dites respectivement d'espèce A^* ou B^* suivant que les trajectoires du groupe constituent ou non un système d'asymptotiques. Par l'emploi du système complètement intégrable déterminant, à une projectivité près, une surface (x) rapportée à des coordonnées homogènes normalisées au sens de Wilczyński, il est tout d'abord montré que les déformations des surfaces admettant un groupe G_1 ou G_2 de déformations (p.s.) conservent la normalisation de Wilczyński à des infiniment petits du $2^{\text{ème}}$ ordre près, puis sont établies un certain nombre de propriétés où interviennent les translations projectivo-similaires (introduites par l'auteur comme généralisation des translations projectives), les lignes de Darboux, les surfaces de coïncidence, les pangéodésiques, les lignes de

Segre et les congruences W. Vient ensuite la détermination des surfaces admettant ∞^1 déformations (p.s.). Pour les surfaces d'espèce A^*, après la mise en équations du problème, l'auteur explicite quelques familles de telles surfaces dépendant de trois constantes arbitraires. Et pour les surfaces d'espèce B^*, dont la recherche s'avère un problème nettement plus difficile, il parvient, en imposant aux trajectoires d'appartenir à certaines familles spéciales de courbes, à en déterminer des classes remarquables. Ainsi, si l'on impose aux trajectoires d'être des pangéodésiques et d'appartenir à une congruence W, on obtient des surfaces découvertes par A. Terracini et étudiées par cet auteur et par E. Cartan, et la considération du cas où les trajectoires sont simplement pangéodésiques permet l'explicitation d'une famille à trois paramètres de surfaces B^*. Le passage au domaine complexe conduit à une classe de surfaces B^* admettant un groupe G_2 de déformations infinitésimales du type (p.s.), à savoir les surfaces de coïncidence, et l'auteur attire l'attention sur le problème de savoir s'il existe d'autres surfaces B^* admettant un tel groupe G_2 de déformations (p.s.). *P. Geometrische Deutungen der differentialgeomet[rischen] Invarianten eines Geradenkomplexes des euklid[ischen] Raumes.

C. R. Acad. Bulgare Sci. **17** (1964), 331–334.

Die Infinitesimalverschiebungen des kanonischen Koordinatensystems $Ae_1e_2e_3$, welches mit der Geraden eines Geradenkomplexes im euklidischen Raum verbunden ist, werden wie bekannt durch die Formeln $dA=\omega_i e_i$, $de_i=\omega_{ik}e_k$, $\omega_{ik}=-\omega_{ki}$, $\omega_2=a\omega_3$ $(i, k=1, 2, 3)$ gegeben. In der Arbeit werden die Invariante a und die weiteren neun Invariante, die als Koeffizienten in den Gleichungen $\omega_{12}=x_1\omega_1+x_2\omega_{31}+x_3\omega_{32}$, $da=x_3\omega_1+x_4\omega_{31}+x_5\omega_{32}$, $\omega_3=(ax_1-x_2)\omega_1+(ax_2-x_5)\omega_{31}+(ax_3-x_6)\omega_{32}$ (welche man aus den vorherstehenden Gleichungen ableiten kann) vorkommen, mit Hilfe passend gewählten geometrischen Objekte, die mit der Geraden des Komplexes verbunden werden, geometrisch interpretiert. *A. Infinitesimal dually conformal transformations of line complexes. (Russian)

Trudy Tomsk. Gos. Univ. Ser. Meh.-Mat. **168** (1963), 167–182.

Infinitesimal transformations of a geometric object in three-dimensional affine space are defined in terms of a moving frame, and it is shown that they form a group. The method is applied to infinitesimal transformations of line complexes in E^3. Conditions are given under which a complex K is transformed into its first differential neighborhood, i.e., a line L of K goes into a line common to all complexes touching K at L. Using the well-known representation of lines in terms of dual numbers suggests an obvious definition of dually conformal maps. The complexes in E^3 which admit groups of infinitesimal dually conformal transformations into themselves are discussed in some detail; also, explicit examples are given.

On an equi-affinely invariant class of pairs of congruences. (Russian)

Trudy Tomsk. Gos. Univ. Ser. Meh.-Mat. **168** (1963), 161–166.

The following was shown by E. T. Ivlev in a paper on a pair of congruences in the equi-affine geometry of three-dimensional space [same Trudy **168** (1963), 103–119; MR **30** #2416b]. Each pair of corresponding rays of an arbitrary equiaffine pair of line congruences lies on two pairs of ruled surfaces belonging to the pair, such that each pair contains one ruled surface whose asymptotic plane is parallel to the corresponding ray of the other ruled surface. These pairs of ruled surfaces are called A-pairs. In the construction of a canonical frame [loc. cit.] these pairs of congruences were excluded, when both A-pairs coincide. The present paper deals with this case. It is shown, for example, that these pairs of congruences still depend on five arbitrary functions, that the singular points of the lines of an A-pair are quasiflecnodal points, and that both surfaces of an A-pair are cylindroids. Some special cases are discussed. *H. Busemann* (Los Angeles, Calif.)

Families of linear elements which are bent by completely geodesic families. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 3 (40), 28–35.

In vorhergehenden Arbeiten der Jahre 1959 bis 1963 [siehe z.B. Mat. Sb. (N.S.) **60** (102) (1963), 411–434; MR **27** #686] hatte Verfasser die Klasse homogener Räume und die Invarianten ihrer affinen Zusammenhänge untersucht; insbesondere vollständig geodätische Untermannigfaltigkeiten dieser Räume. Die Ergebnisse fanden Anwendung im konkreten Falle des homogenen Raumes m_5, der Gesamtheit aller Linienelemente des euklidischen Raumes. Nunmehr handelt es sich um die Entwicklung einer allgemeinen Methode zur Bestimmung homogener Untermannigfaltigkeiten, die von Untermannigfaltigkeiten gegebener Klasse eingehüllt werden, nämlich von Linienelementvereinen, die vollständig aus geodätischen Untermannigfaltigkeiten bestehen. Alle diese Linienelementvereine ergeben sich auf gleiche Weise und gestatten eine einfache geometrische Charakterisierung. Ihre analytische Behandlung wird unter Verwendung kanonischer Begleitsimplices auf die Integration Pfaffscher Systeme zurückgeführt. Zunächst werden notwendige und hinreichende Bedingungen für die Berührung der Klasse $\mathscr{F}$ angegeben. Weiterhin werden zunächst die vierparametrigen Elementvereine behandelt. Sie zerfallen in drei Klassen. Dann folgt die Theorie dreidimensionaler Elementvereine, welche bereits sechs Fälle unterscheidet. Im letzten Abschnitt wird noch auf zweiparametrige Fälle eingegangen (mit 9 weiteren Unterfällen).

The metric tensor, inertia tensor, and stress tensor. (Spanish)

Univ. Nac. Ingen. Inst. Mat. Puras Apl. Notas Mat. **1** (1962/63), 1–34.

These are notes presumably written for students of the Univ. Nac. Ingen. and give a classical presentation of vectors and second-order tensors. Nineteen pages are devoted to vectors, and the remaining part to examples of metric, inertia and stress tensors. *J. Kestens* (Brussels)

Pach, Klára; Frey, Tamás 6430

★**Vector and tensor analysis.**

Terra, Budapest, 1964. 596 pp. $14.00.

Although this book is intended for undergraduate engineers, it has many features that will appeal to other students. First, the authors introduce scalars, vectors, and the various products of these quantities via the usual Gibbs approach. This is followed by a detailed discussion of differentiation and the properties of the gradient. These first three chapters contain many applications to analytic and differential geometry and kinematics. Chapter 4 treats the various integral forms of Stokes's theorem and concludes the standard type of introduction to vector analysis. However, the next three chapters, which deal with vector and tensor fields, furnish several interesting developments. For instance, the introduction of a norm for A_{ik}, a second-order tensor (the norm is defined as the trace of the product of the matrix A_{ik} and its transpose $A_{ik}^*=A_{ki}$) and the discussion of some inequalities involving this norm are given. Further, applications to hydrodynamics and potential theory are furnished.

The exposition is in "theorem-proof" form and is clear except in a few sections. The only defect in the text is a

tendency to oversimplify some general theory. An example of this is the "embedding problem" which is discussed on page 564. However, the text is interesting and should be of considerable value to engineering and other students. *N. Coburn* (Ann Arbor, Mich.)

The foundations of differential geometry and modern algebra. (Russian)

Proc. Fourth All-Union Math. Congr. (Leningrad, 1961), Vol. I, pp. 17–29. *Izdat. Akad. Nauk SSSR, Leningrad,* 1963.

From time to time a paper appears in which it is shown how far present-day differential geometry deviates from the principles laid down in the Erlangen programs. "For contemporary differential geometry", writes the author, "the concept of group is quite insufficient for the examination, from an algebraic point of view, of the basic concepts of the corresponding geometrical theories. Moreover, algebraic problems arising in investigations concerning the foundations of contemporary differential geometry require the study of special algebraic systems which at present are not very seriously discussed". The author indicates some of the reasons for criticism: the local character of usual differential geometry, the use of functions whose existence is only confirmed by the classical existence theorems which are also local in character, the difficulties met in understanding the operations of multiplication as binary relations in the partial transformations of spaces under classical Lie groups. An elementary example is found in the set of all projective transformations of n-dimensional arithmetic space, where every transformation has a singular hyperplane. The author now endeavors to give an outline of a modern approach to differential geometry, an approach first undertaken by Veblen and Whitehead in their monograph of 1932 [*The foundations of differential geometry*, Cambridge Univ. Press, London, 1932]. The investigation of binary relations owes much to J. Riguet [Bull. Soc. Math. France **76** (1948), 114–155; MR **10**, 502], that of generalized groups to previous work by the author [e.g., Ukrain. Mat. Ž. **8** (1956), 235–253; MR **20** #3924; see also Dokl. Akad. Nauk SSSR **84** (1952), 1119–1122; MR 14, 12].

Some characterizations of the complete integrability of a given Pfaffian system by means of the Lie derivative.

Bol. Soc. Mat. São Paulo **15** (1960), 37–46 (1964).

Let M be a connected, analytic, real differentiable manifold, $E^h(x)$ an h-dimensional subspace of the tangent space at x, and $\hat{E}^{n-h}(x)$ a subspace of the cotangent space at x orthogonal to $E^h(x)$. Let $\Pi: x\to E^h(x)$ be an h-dimensional field (a distribution) defined over M_n, and $V(x)$ a local analytic h-vector representing Π, and let $\hat{V}^{n-h}(x)$ be defined in a similar fashion. Then it is proved that Π is completely integrable if and only if either of the following conditions is true: (1) $L_v(V)=f_v(x)V$ for any v contained in Π, where L_v is the Lie derivative and $f_v(x)$ is a local analytic function depending on v; (2) $L_v(\hat{V})=f_v(x)\hat{V}$.

A new type of vector field and invariant differential systems.

Proc. Amer. Math. Soc. **15** (1964), 675–678.

In another paper [same Proc. **15** (1964), 432–437, MR **29** #526], the author defined and studied k-vector fields associated to mappings from a manifold N to a manifold M. In this paper, he continues the study and shows the analogy with classical continuous groups. Defining a system Σ of partial differential equations as a finitely generated ideal in $C^\infty(J^k)$, where $J^k=J^k(N, M)$ is the manifold of k-jets $j_x^k(f)$ of maps $f: N\to M$, and using the notions of prolongations of k-vector fields and of systems of partial differential equations, the author shows that in the real analytic case, if θ is a k-vector field leaving Σ invariant, then the integral curves of θ which pass through one solution of Σ yield solutions for all parameter values. *E. T. Kobayashi* (Evanston, Ill.)

Nguyen-Van-Hai 6439

Un type de connexion linéaire invariante sur un espace homogène.

C. R. Acad. Sci. Paris **259** (1964), 2065–2068.

The author continues his investigation of invariant affine connections on homogeneous spaces [same C. R. **258** (1964), 3952–3955; MR **29** #1599; ibid. **259** (1964), 49–52; MR **29** #3995]. He constructs an invariant connection (called a connection of special type) on a homogeneous space satisfying certain conditions which are met by any reductive homogeneous space in the sense of Nomizu. Assuming that a homogeneous space with invariant connection of special type admits also an invariant pseudo-Riemannian metric, he studies the relationship between the invariant connection of special type and the Levi-Civita connection defined by the metric.

S. Kobayashi (Berkeley, Calif.)

Yano, K.; Ledger, A. J. 6440

Linear connections on tangent bundles.

J. London Math. Soc. **39** (1964), 495–500.

From the authors' introduction: "It is shown in a recent paper by Dombrowski [J. Reine Angew. Math. **210** (1962), 73–88; MR **25** #4463] that if M is a C^∞ manifold with a linear connection ∇, then the tangent bundle $T(M)$ of M admits an almost complex structure determined by ∇. Furthermore, a Riemannian metric on M determines a Kahlerian metric on $T(M)$. We show in this paper that ∇ on M determines a linear torsion free connection on $T(M)$. In order to do this we first consider certain vector fields on $T(M)$, in addition to the horizontal and vertical lifts of vector fields of M. In particular, we show that $T(M)$ admits a non-trivial vector field which is independent of any connection or vector field on M."

A. M. Rodrigues (São Paulo)

Arregui, J. 6441

The infinitesimal connection of a differentiable manifold X as a representation of the differential determined by the topological space X. (Spanish)

Rev. Mat. Hisp.-Amer. (4) **23** (1963), 57–74.

The author's intention is to give a specific illustration of material found in papers of Botella Raduán [same Rev. (4) **20** (1960), 183–211; MR **23** #A2885; Actas de la Primera Reunión Anual de Matematicos Españoles, pp. 110–117, Universidad de Madrid, Madrid, 1961; MR **24** #A3638]. He first gives explicit coordinate representations of the group of projective collineations leaving the vertices of a Euclidean simplex fixed and the interior invariant. Then for a differentiable manifold X he considers coordinate systems having a Euclidean simplex as range, and thus induces local groups of homeomorphisms on X, as discussed in the first of the references cited. These local groups are tied together rather artificially, giving a presheaf of groups, the sheaf of which illustrates Botella Raduán's differential.

A linear connexion is assumed given and is used to prolong the infinitesimal transformations given by the local group to the bundle of bases. The prolongation is nothing more than the horizontal space of the connexion. The author calls it the geometric representation of the differential (sheaf) but the reviewer fails to see how it represents anything but the connexion itself.

R. L. Bishop (Urbana, Ill.)

Tashiro, Yoshihiro 6442

An example of non-complete affine connection on a torus. (Japanese)

Sûgaku **15** (1963/64), 221.

The author gives an example of a compact affinely connected manifold which is not complete. Let T^2 be a torus with coordinate system (x, y) (mod 2π), and consider an affine connection whose geodesics are given by

$$x''+x'^2\sin^2 x-y'^2\cos^2 x = 0 \quad\text{and}\quad y''+x'^2+y'^2 = 0.$$

Then the geodesic given by $x=t$ and $y=\log\cos t$ ($|t|<\pi/2$) is not extendible to $t=\pi/2$. A simpler example of non-complete affine connection on a circle was constructed by Auslander and Markus [Ann. of Math. (2) **62** (1955), 139–151; MR 17, 298]. Contrary to the statement made by the author, there exists also a simply connected, compact, affinely connected manifold which is not complete [see Kobayashi and Nomizu, *Foundations of differential geometry*, Vol. I, p. 292, Interscience, New York, 1963; MR **27** #2945]. *S. Kobayashi* (Berkeley, Calif.)

Vedernikov, V. I. 6443

A pseudo-linear connection. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, *no.* **2 (39)**, 41–52.

Verfasser geht aus von einem zentralaffinen Raum E_{n+1} mit ausgezeichnetem E_n; dieser E_{n+1} wird aud eine Vektorbasis $e_0, e_1, \cdots, e_n$ bezogen, wobei $e_1, \cdots, e_n$ den E_n aufspannen. Nach dem Muster von Cartan werden dann die infinitesimalen Änderungen dieses System durch $de_0=\omega_0{}^0e_0+\omega_0{}^ie_i$, $de_i=\omega_i{}^ke_k$ beschrieben, wobei die ω ein System Pfaffscher Formen bedeuten, die die Strukturgleichungen

$$d\omega_0{}^0 = 0, \qquad d\omega_0{}^i-(\omega_0{}^0\wedge\omega_0{}^i+\omega_0{}^k\wedge\omega_k{}^i) = 0$$

erfüllen. Nach dem Vorbild von E. Cartan verallgemeinert sich dann dies System der Strukturgleichungen zu einem nicht holonomen System, indem man die rechten Seiten nicht gleich 0 setzt, sondern gleich gewissen

äußeren Differentialformen 2. Grades Ω_0^0, Ω_0^i und Ω_i^k. Die ω_i^j definieren eine Übertragung, deren Torsion durch die ω_0^i bestimmt ist. Es wird in der Arbeit meist Torsionsfreiheit, d. h. $\omega_0^1 = \cdots = \omega_0^n = 0$ vorausgesetzt. Die übrigen Formen werden zu einer Matrix $\omega_0 = \begin{pmatrix}\omega_0^0 & 0\\ 0 & \omega_k^j\end{pmatrix}$ zusammengefaßt, und es wird untersucht, wie diese Matrix sich bei der Untergruppe G aller zentralen Affinitäten verändert, die außer E_n noch die Richtung des Vektors e_0 unverändert lassen. Die Gruppe G wird durch Matrizen der Art $A_1 = \begin{pmatrix}\sigma & 0\\ 0 & \sigma a_i^k\end{pmatrix}$ beschrieben, und ω_0 geht bei den infinitesimalen Transformationen von G, die auch die statische Gruppe der Richtung e_0 heißt, in die Formenmatrix $\tilde{\omega}_0$ über, die sich durch

$$\tilde{\omega}_0 = (dA_1)A_1^{-1} + A_1\omega_0 A_1^{-1}$$

berechnet. Die Formen der Matrix $\tilde{\omega}_0$ definieren den sogenannten pseudolinearen Zusammenhang. Dieser läßt sich auffassen als ein affiner Zusammenhang in dem gefaserten Raum $P(B, G)$; dabei ist G eine n-dimensionale Mannigfaltigkeit mit den Parametern $u^1, \cdots, u^n$, und die Gruppe G tritt als Faser auf. Bei Festlegung der Funktion $\sigma(u^1, \cdots, u^n)$ definieren die $\tilde{\omega}_i^k$ einen linearen Zusammenhang, und der pseudolineare Zusammenhang erweist sich somit als eine Gesamtheit linearer Zusammenhänge. Es werden dann Pseudotensoren, ein kovariantes Differential und damit eine Parallelverschiebung bei pseudolinearen Zusammenhängen erklärt. Als besonderer Fall wird der sogenannte Weylsche Zusammenhang behandelt, bei dem eine Bilinearform $g_{ij}u^iw^j$ sich als invariant bei pseudoparalleler Verschiebung der Vektoren u^i, w^j erweist.

Vedernikov, V. I. 6444

On conjugate connections. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1964**, no. 4 (41), 19–29.

Verfasser betrachtet als Grundbereich die Gesamtheit der ∞^{2n} Paare (A, ξ), wobei A ein Punkt und ξ eine Hyperebene des projektiven Raumes Π_n bedeuten. Die Gesamtheit dieser Paare wird durch $(n+1)^2$ Grundpaare (A_i, ξ^j) je der Punkte $A_0, \cdots, A_n$ und Seiten $\xi^0, \cdots, \xi^n$ eines Grundsimplex aufgespannt. Dann rechnet der Verfasser die Ableitungsformeln

$$dA_i = \omega_i^0 A_0 + \omega_i^\beta A_\beta, \qquad d\xi^j = \omega^*{}_0{}^j\xi^0 + \omega^*{}_\beta{}^j\xi^\beta$$

aus, die sich bei infinitesimaler Änderung des Grundsimplex ergeben. Unter der statischen Gruppe des Paares (A_0, ξ^0) wird die Gesamtheit derjenigen Kollineationen verstanden, die (A_0, ξ^0) unverändert lassen. Dann ergibt sich durch einfache Rechnung: Bezeichnet man mit $A = (a_\alpha{}^\beta)$ eine reguläre (n, n)-Matrix, ihre Inverse $A^{-1} = (b_\alpha{}^\beta)$, und ist σ eine Konstante, so gehen die Pfaffschen Formen ω_i^j bei den Transformationen der statischen Gruppe von (A_0, ξ^0) über in $\tilde{\omega}_i^j$ mit $\tilde{\omega}_0{}^\alpha = \omega_0{}^\beta b_\beta{}^\alpha$, $\tilde{\omega}_0{}^0 = \omega_0{}^0 + d\log\sigma$, $\tilde{\omega} = dA\cdot A^{-1} + A\omega A^{-1} + d\log\sigma\cdot E$. Darin bedeuten $\tilde{\omega}$ die Formenmatrix $\tilde{\omega}_\alpha{}^\beta$ $(\alpha, \beta = 1, \cdots, n)$ und E die Einheitsmatrix. In dem mit Π_n verbundenen Dualraum $\Pi_n{}^*$ ergeben sich analog Formen $\tilde{\omega}^*{}_\alpha{}^\beta$. Die $\omega_\alpha{}^\beta$ und die $\tilde{\omega}^*{}_\alpha{}^\beta$ definieren je einen pseudolinearen Zusammenhang [siehe #6443] und diese beiden pseudolinearen Zusammenhänge heißen konjugiert zueinander. Mit ihnen sind durch die Formen der Matrizen $\tilde{\theta} = \tilde{\omega} - \tilde{\omega}_0{}^0E$ und $\tilde{\theta}^* = \tilde{\omega}^* - \tilde{\omega}_0{}^0E$ lineare Zusammenhänge verbunden, die gleichfalls zueinander konjugiert heißen. Durch die Pfaffschen Gleichungen $\omega_\alpha{}^0 = b_{\alpha\beta}\omega_0{}^\beta$ wird eine Abbildung der Punkte von Π_n in die Menge der Hyperebenen definiert. Im besonderen Fall der Symmetrie von $b_{\alpha\beta}$ ist der durch θ definierte Zusammenhang projektiv euklidisch.

Ulteriori contributi allo studio delle varietà riemanniane a connessione costante.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 60–85.

This paper contains some further results in the author's researches on Riemannian manifolds with constant coefficients of connection. It depends upon certain results obtained in a previous note by the author [same Atti **96** (1961/62), 451–462; MR **25** #5477] and also modifies certain of the results given in the note mentioned. The main part of the research concerns Riemannian manifolds V_n "of class C_p" whose fundamental tensor $g_{ij}(x)$ can be written in the form $\phi_\alpha a_{ij}{}^{(\alpha)}$ $(\alpha = 1, 2, \cdots, p)$, where the ϕ_α are functions of x and the $a_{ij}{}^{(\alpha)}$ are constants in a certain system of coordinates called coordinates C. In this paper the non-Euclidean V_n of type C_2 are taken particularly into consideration, and an exhaustive classification is given of spaces of this class.

Pignedoli, Antonio 6446

Sulle "famiglie naturali di curve" di Kasner.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 221–251.

E. Kasner [Trans. Amer. Math. Soc. **10** (1909), 201–219] hatte "natürliche Kurvenfamilien" in die Dynamik als Extremalen von Variationsproblemen der Form $\int F\,ds$ = min mit beliebigen Funktionen F des Ortes eingeführt. Der Verfasser untersucht diese Kurvenfamilien in eingehender Weise und stützt sich hierbei auf die Differentialgleichung und ihre Integrationsmöglichkeiten. Im besonderen wird auf die speziellen Kurvenklassen von Brachistochronen, geodätischen Linien und Kettenlinien der Mannigfaltigkeit V_n das Augenmerk gerichtet, die auch schon Kasner betrachtet hat.

H. R. Müller (Braunschweig)

Sen, R. N.; Mittra, S. S. 6447

On a sequence of conformal Riemannian spaces.

Bull. Calcutta Math. Soc. **54** (1962), 107–121.

Let g_{ij} be the metric tensor of a Riemannian space, and let λ_i, μ_i be two covariant vector fields which are nowhere zero and nowhere orthogonal. Denote the product of the lengths of these vectors by l and the angle between them by θ. Then, as a specialisation of a previous paper by R. N. Sen [Proc. Nat. Inst. Sci. India Part A **26** (1960), suppl. II, 14–20; MR **25** #522], the authors consider the sequence of metric tensors

$$g_{ij}{}^{(2p-1)} = l^2\cos^{2p}\theta\, g_{ij}, \qquad g_{ij}{}^{(2p)} = \sec^{2p}\theta\, g_{ij}.$$

Assuming that l is constant, relations are found between the curvature tensors of the metrics in this sequence, and these are applied to obtain necessary conditions for pairs of spaces in the sequence to be Einstein spaces.

Singal, M. K. 6448

Normal curvature of a vector field in a hypersurface V_n imbedded in a Riemannian V_{n+1}.

Rend. Circ. Mat. Palermo (2) **12** (1963), 275–290.

Wakakuwa, Hidekiyo 6449

Remarks on 4-dimensional differentiable manifolds.

Tôhoku Math. J. (2) **16** (1964), 154–172.

The author classifies Riemannian 4-manifolds X_4 according to restricted homogeneous holonomy, taking the viewpoint of linear Lie groups. Roughly speaking, much of the paper covers material considered from the viewpoint of structure equations by Ishihara [J. Math. Soc. Japan 7 (1955), 345–370; MR 18, 599] and based on Chern's report [Bull. Amer. Math. Soc. 51 (1945), 964–971; MR 7, 216]. The classification of possible restricted homogeneous holonomy groups for X_4 is a straightforward exercise in Lie theory. Then some examples are given, the various almost-complex structures present are considered, and the vanishing of Nijenhuis tensors of the latter is discussed. The reviewer finds the paper useful for testing conjectures in dimension 4.

Sur la courbure intégrale d'une classe de courbes. (Polish and Russian summaries)

Ann. Univ. Mariae Curie-Skłodowska Sect. A **16** (1962), 19–40 (1964).

Cet article constitue un apport intéressant à la géométrie externe des lignes géodésiques d'une surface convexe. Il se relie principalement à H. Busemann et W. Feller [Acta Math. **66** (1936), 1–47] et à A. D. Alexandrov [*Intrinsic geometry of convex surfaces* (Russian), OGIZ, Moscow, 1948; MR **10**, 619] dont plusieurs résultats sont utilisés. Toutes les courbes et les surfaces considérées sont situées dans l'espace euclidien à trois dimensions. $\langle A*B\rangle$ désigne une courbe d'extrémités A et B, $\mathfrak{K}$ la classe des courbes $\langle A*B\rangle$ vérifiant les conditions suivantes: $\langle A*B\rangle$ admet en tout point M les vecteurs (unitaires) demi-tangents $\mathfrak{t}^+=\mathfrak{t}^+(M)$ et $\mathfrak{t}^-=\mathfrak{t}^-(M)$ tels que, pour $M\to M_0{}_+$, $\lim \mathfrak{t}^+(M)=\lim \mathfrak{t}^-(M)=\mathfrak{t}^+(M_0)$, que, pour $M\to M_0{}_-$, $\lim \mathfrak{t}^+(M)=\lim \mathfrak{t}^-(M)=\mathfrak{t}^-(M_0)$ et que $\mathfrak{t}^+(M_0)\neq -\mathfrak{t}^-(M_0)$. Les courbes de $\mathfrak{K}$ sont rectifiables, on peut prendre comme paramètre la longueur d'arc s comptée à partir de A: vecteur $\overline{AM}=\mathfrak{r}(s)$. Par "tangente au sens strict" $\mathfrak{t}(M)$ est entendue la limite unique des droites $M'M''$ où M' et M'' sont deux points distincts de $\langle A*B\rangle$ tendant vers M, par "plan osculateur au sens de Menger" $\sigma(M)$ la limite unique des plans passant par trois points M', M'' et M''' de $\langle A*B\rangle$ non alignés et tendant vers M, par "normale orientée" de $\sigma(M)$ la limite unique dans les mêmes circonstances du quotient du produit vectoriel $\overline{M'M''}\times\overline{M''M'''}$ par $|\overline{M'M''}\times\overline{M''M'''}|$, les points étant rangés dans l'ordre des paramètres croissants. Si $\langle A*B\rangle$ inclut un segment de droite I, on prendra comme plan osculateur en un de ses points M un plan passant par I "convenant le mieux au problème considéré", mais le même en tous les points de I. Pour une courbe $\langle A*B\rangle$ de $\mathfrak{K}$ on donne aux vecteurs $\mathfrak{t}^+(M)$ et $\mathfrak{t}^-(M)$ une origine fixe O. Aux points où $\mathfrak{t}^+\neq\mathfrak{t}^-$, on joint les extrémités par un arc de grand cercle de longueur inférieure à π. On obtient ainsi une courbe (continue) dite "indicatrice sphérique" de la courbe $\langle A*B\rangle$ et notée $\langle\langle A*B\rangle\rangle$. La longueur de $\langle\langle A*B\rangle\rangle$ est appelée "courbure intégrale" de $\langle A*B\rangle$ et désignée par $k(\langle A*B\rangle)$. S désigne la surface fermée limitant un solide convexe ayant des points intérieurs. S est dite "lisse" si elle admet en chacun de ses points un plan tangent continu. Théorème 1: Une géodésique sur une surface convexe lisse S admet en tout point $M\in\langle A*B\rangle$ un plan osculateur au sens de Menger continu, orienté, perpendiculaire au plan tangent à la surface au point M. Théorème 2: L'indicatrice sphérique d'une géodésique $\langle A*B\rangle$ sur une surface convexe lisse est une courbe $\langle\langle A*B\rangle\rangle$ admettant une tangente au sens strict. Théorème 3: Si la suite de surfaces convexes lisses S_n tend vers une surface convexe lisse S, si la suite des géodésiques $C_n=\langle A_n*B_n\rangle$ de S_n tend vers la géodésique $C=\langle A*B\rangle$ de S et si ces courbes sont rapportées à un même paramètre x, $x_0\leq x\leq x_1$, $C_n: M_n(x)$, $C: M(x)$, tel que, pour tout x, $M_n(x)\to M(x)$, alors la courbure intégrale $k_n(x)$ de $\langle A_n*M_n(x)\rangle$ tend uniformément vers la courbure intégrale $k(x)$ de $\langle A*M(x)\rangle$. Théorème 4 exprime une propriété analogue pour une suite de lignes brisées (polygonales) inscrites dans une géodésique $\langle A*B\rangle$ sur une surface convexe lisse et convergeant vers $\langle A*B\rangle$. Théorème 5 donne des conditions pour qu'une suite de courbes $\langle A_n*B_n\rangle\in\mathfrak{K}$ convergeant vers une courbe $\langle A*B\rangle\in\mathfrak{K}$, l'on ait

$$\lim k(\langle A_n*B_n\rangle) = k(\langle A*B\rangle).$$

Ces résultats visent à un théorème principal qui se trouve dans l'article suivant de l'auteur [Ann. Univ. Mariae Curie-Skłodowska Sect. A **16** (1962), 41–51; MR **29** #1605] et qui exprime la déviation linéaire $\mathfrak{r}(s)-s$ d'une géodésique d'une surface convexe lisse comme une intégrale faisant intervenir la courbure totale $k(x)=k(\langle A*M(x)\rangle)$. Les résultats obtenus pour les géodésiques des surfaces convexes lisses sont valables pour des courbes plus générales ainsi que le signalent des remarques. (Remarque du rapporteur. Le théorème de la Thèse du rapporteur cité p. 35 [*Les méthodes directes en géométrie différentielle*, Actualités Sci. Indust., No. 886, Hermann, Paris, 1941; MR 7, 67] recèle une erreur concernant la suffisance de la condition ainsi que l'a signalé E. J. van der Waag [Nederl. Akad. Wetensch. Proc. Ser. A **54** (1951), 390–403; MR **13**, 771] mais la conclusion qu'en tire l'auteur est correcte.) *Chr. Y. Pauc* (Nantes)

Infinitesimal transformations of almost Hermitian spaces. (Japanese)

Sûgaku **16** (1964), 18–27.

This paper is a relevant exposition of recent developments in the field of infinitesimal transformations in almost Hermitian manifolds and in locally product manifolds. The author gives 20 theorems, including the following, with concise proofs, and mentions those manifolds to which these theorems have been generalized. (1) An almost analytic function in a compact almost complex manifold is a constant. (2) An infinitesimal isometry in a compact Kählerian manifold is an automorphism. (3) A harmonic vector in a compact Kählerian manifold is locally a gradient of an analytic function. (4) An infinitesimal conformal or projective transformation in a compact Kählerian manifold is isometric. (5) An infinitesimal conformal or projective transformation in a compact locally product manifold is isometric. (6) An infinitesimal holomorphically projective transformation in a compact manifold is analytic. (7) An infinitesimal analytic transformation preserving the differential form $4\varphi_\lambda{}^a R_{a\mu} dx^\lambda \wedge dx^\mu$ in a compact Kählerian manifold is an automorphism.

On the existence of measure for singular hyperquadrics in projective spaces. (Spanish)

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 269–276.

It is known that sets of projectively equivalent non-singular hyperquadrics have an invariant measure with respect to the projective group [the reviewer, Publ. Math. Debrecen **7** (1960), 226–237; MR **22** #12499; M. I. Stoka, Acad. R. P. Romîne Bul. Şti. Secţ. Şti. Mat. Fiz. **7** (1955), 903–937; MR **18**, 63]. In this paper the author proves that such an invariant measure does not exist for sets of singular hyperquadrics. However, there exists an invariant measure for sets of pairs of hyperquadrics whose vertices (locus of singular points) are linear spaces L_r, L_s which do not intersect each other and have complementary dimensions ($r+s=n-1$) and for sets of pairs of singular hyperquadrics whose vertex is of dimension r and linear spaces of dimension $n-r-1$ without common point with the vertex of the hyperquadric.

Stoka, Marius I. 6460

Géométrie intégrale dans un espace E_n.

Univ. Nac. Tucumán Rev. Ser. A **14** (1962), 25–59.

A Lie group of transformations is said to be measurable if it possesses one and only one integral invariant, up to a constant factor. The author gives the conditions of

measurability of a given r-parameter group G, operating in euclidean space E_n in terms of the infinitesimal transformations and the constants of structure of the group, and deduces some consequences and applications. Let F_q be a family of q-dimensional varieties in E_n and G the maximum group of transformations which leaves F_q invariant; the relations between the measurability of G and that of its subgroups are investigated. Most of the results, which are given clearly and systematically here, have been previously published by the author [Acad. R. P. Romîne Stud. Cerc. Mat. **9** (1958), 547–558; MR **21** #2285; Boll. Un. Mat. Ital. (3) **13** (1958), 470–485; MR **21** #2284; ibid. (3) **14** (1959), 467–476; MR **22** #4041; Rev. Math. Pures Appl. **4** (1959), 123–156; MR **22** #5005a; Rend. Circ. Mat. Palermo (2) 8 (1959), 192–205; MR **22** #5005b]. *L. A. Santaló* (Buenos Aires)

GENERAL TOPOLOGY

Tondeur, Philippe 6461

Ein Beispiel zur allgemeinen Topologie: Die Topologie einer Äquivalenzrelation.

Ann. Acad. Sci. Fenn. Ser. A I No. 344 (1964), 7 pp.

Let ρ be a relation on the set X. The operator $\varphi(A) = \{p \mid p\rho q$ for some $q \in A\}$ $(A \subset X)$ is a Kuratowski closure operator on X if and only if ρ is reflexive and transitive. If ρ is, in addition, symmetric, then the resulting topology (denote it τ_ρ) is normal, locally compact, locally connected and first countable. τ_ρ is compact if and only if X/ρ is finite. Let ρ and σ be equivalence relations on the sets X and Y, respectively. A function $f: (X, \tau_\rho) \to (Y, \tau_\sigma)$ is continuous if and only if f maps ρ-equivalent points into σ-equivalent points. There are further results. *J. Mayer* (Albuquerque, N.M.)

Lynn, I. L. 6462

Linearly orderable spaces.

Trans. Amer. Math. Soc. **112** (1964), 189–218.

A topological space is linearly orderable if a linear ordering can be introduced into the space so that the original topology coincides with the interval topology. In an earlier note [Proc. Amer. Math. Soc. **13** (1962), 454–456; MR **25** #1536] the author gave a sufficient condition for a topological space to be linearly orderable. In the present paper sufficient conditions for a subspace of the real line to be linearly orderable are given. The following is the main theorem of the paper. Let X be a subspace of the real line R, and let $\eta(X)$ be the set of end points of the open ends of those components of $R \sim X$ which are half-open intervals. If no open subset of X is compact and $\eta(X)^- \cap X$ is countable (the closure being taken in R), then X is linearly orderable. The proof of the main theorem is quite long and occupies most of the paper. From this theorem, it follows that if a subspace X of R satisfies any of the following conditions, X is linearly orderable: (1) no open subset of X is compact and X has only countably many components, (2) X is a union of intervals containing no isolated closed (in R) interval, and (3) X is a union of open or half-open intervals. *I. Namioka* (Seattle, Wash.)

Day, Mahlon Marsh 6463

Correction to my paper "Fixed-point theorems for compact convex sets".

Illinois J. Math. **8** (1964), 713.

A left-invariant mean on $C(S)$, the space of all bounded continuous functions on the topological semigroup S, exists if and only if for each compact convex set K in each l.c.s. and for each homomorphism τ of X into the semigroup of affine continuous self-maps of K, with $[\tau s](y)$ continuous for some $y \in K$, there is a $p \in K$ such that $\sigma(p) = p$ for all $\sigma \in \tau(S)$.

This result replaces an incorrect remark made in a previous paper [same J. **5** (1961), 585–590; MR **25** #1547]. *M. Edelstein* (Halifax, N.S.)

Grace, E. E.; Heath, R. W. 6464

Separability and metrizability in pointwise paracompact Moore spaces.

Duke Math. J. **31** (1964), 603–610.

Alexandrov [Uspehi Mat. Nauk **15** (1960), no. 2 (92), 25–95; MR **22** #9947] introduced the notion of a "uniform base" in order to state (in part) the following metrization theorem: A regular space is metrizable if it has a uniform base and is paracompact or collectionwise normal. But, in order that a regular space have a uniform base, it is necessary and sufficient that it be a pointwise paracompact Moore space. Bing had already shown [Canad. J. Math. **3** (1951), 175–186; MR **13**, 264] that a Moore space is metrizable if it is paracompact or collectionwise normal. Thus, in Alexandrov's theorem, pointwise paracompactness is an unnecessary part of the notion of a uniform base. In the paper under review, metrization theorems are obtained in which pointwise paracompactness is necessary.

Suppose that S is a connected, pointwise paracompact Moore space (or equivalently, a connected, regular (T_1) space with a uniform base). Then S is separable (and hence metrizable) if (1) no point separates S and (2) for $p, q \in S$ $(p \neq q)$ there exists a closed, connected, separable set arbitrarily close to p which separates p from q or if (1) no point separates S, (2) S is locally connected and (3) for $p, q \in S$ $(p \neq q)$ there exists a closed separable set which separates p from q.

Furthermore, in a locally connected, pointwise paracompact Moore space, every monotonic collection (i.e., inclusion chain) of peripherally separable, connected, open sets contains a countable subcollection running upward through it. Similarly, and somewhat more generally, every connected, locally connected, locally peripherally separable, pointwise paracompact topological space is a Lindelöf space. Other results of a related nature are obtained. *F. Burton Jones* (Riverside, Calif.)

McCandless, Byron H. 6465

Perfect normality, local neighborhood extension spaces, and contractibility of absolute retracts.

Math. Z. **85** (1964), 385–391.

Let P denote the class of perfectly normal spaces. The author reviews the relation of P to the classes of collectionwise normal, of paracompact, and of Lindelöf spaces; he characterizes the metric absolute G_δ's by the perfect normality of certain spaces. Though the extension of certain results of Hanner [Ark. Mat. **2** (1952), 315–360; MR **14**, 396; errata, MR **14**, 1278] to the class P is not

straightforward, the author succeeds in proving (1) an AR(P) is contractible, and (2) a countable union of open NES(P) is also an NES(P). {Reviewer's remark: Theorem 7 is contained in a paper of E. Michael [Pacific J. Math. 3 (1953), 789–806, p. 793; MR 15, 547].}

Mosaics of metric continua and of quasi-Peano spaces.
Pacific J. Math. 14 (1964), 1327–1333.

Let X be a mosaic of compact metric spaces X_a, $a \in A$ [see Davison, Trans. Amer. Math. Soc. 91 (1959), 525–546; MR 21 #6575]. The author calls X an m-continuum space if each X_a is connected, and a quasi-curve space if instead each X_a is locally connected. Necessary and sufficient conditions (in terms of convergent sequences in X) are given for a topological space X to be an m-continuum space, and it is shown that X is then the mosaic of all its metrizable subcontinua. Other properties of m-continuum spaces are derived; for example, the components are open and are strongly (continuumwise) connected. Quasi-curve spaces are shown to coincide with curve spaces (for which the X_a's can be taken to be Peano spaces). The paper concludes by mentioning some unsolved problems. *A. H. Stone* (Rochester, N.Y.)

Chiang Chin-he [Jiang, Jia-he] 6467

The essential component of the set of fixed points of multivalued mappings and its application to the theory of games.
Acta Math. Sinica 14 (1964), 451–460 (*Chinese*); *translated as Chinese Math.—Acta* 5 (1964), 485–495.

Kinoshita showed [Osaka Math. J. 4 (1952), 19–22; MR 14, 193] that the set of fixed points of a continuous transformation of the Hilbert cube has an essential component. The author generalizes this to multivalued upper semi-continuous transformations with convex values, for compact convex sets in Banach spaces, with the natural application to sets of equilibrium points in non-cooperative games. *J. R. Isbell* (New Orleans, La.)

Juhász, I. 6468

On extremal values of mappings. I.
Ann. Univ. Sci. Budapest. Eötvös Sect. Math. 6 (1963), 39–42.

The author calls a topological space R a $\sigma(k)$-space if the set of local extreme values of a function into any partially ordered set is always of cardinal $\leq k$. Theorem: If the weight of R (least cardinal of a base) is k, then R is a $\sigma(k)$-space; and if R is a $\sigma(k)$-space, then the least cardinal of a dense set is $\leq k$. It follows that a pseudometric space is a $\sigma(k)$-space if and only if its weight is $\leq k$. The author conjectures that the conclusion holds as well for arbitrary completely regular spaces; in any event, he proves that each completely regular $\sigma(k)$-space has weight $\leq 2^k$. In contrast, he also shows that a $\sigma(k)$-space can have arbitrarily large weight, even if it is T_1.

L. Gillman (Rochester, N.Y.)

Pasynkov, B. 6469

Partial topological products. (Russian)
Dokl. Akad. Nauk SSSR 154 (1964), 767–770.

Consider a space X, a family $\{G_\alpha\}$ of open subsets and a family $\{Z_\alpha\}$ of spaces. A "partial product" $P(X, \{Z_\alpha\}, \{G_\alpha\})$ is defined. For the case of compact spaces Z_α, the definition is equivalent to that of a "local product" introduced by the author [same Dokl. 150 (1963), 40–43; MR 28 #576]; if all G_α are equal to X, then $P(X, \{Z_\alpha\}, \{G_\alpha\})$ coincides with the cartesian product $X \times \prod Z_\alpha$. Seven theorems are given (without proofs); only some simpler results may be stated here.

For any cardinal number n, let $\mathcal{T}^n$ [D^n] denote the cartesian product of n segments [two-point spaces]. Let $\{G_\alpha\}$ be an open base in $\mathcal{T}^n$ and let Z_α be spaces. Then (1) if n is finite and every Z_α is a discrete space of power τ, then $P(\mathcal{T}^n, \{Z_\alpha\}, \{G_\alpha\})$ is universal for all metrizable spaces of dimension $\leq n$ and of weight $\leq \tau$; (2) if every Z_α is discrete of power τ, then $P(\mathcal{T}^{\aleph_0}, \{Z_\alpha\}, \{G_\alpha\})$ is universal for all metrizable spaces of weight $\leq \tau$; (3) if $n \leq \tau$ and Z_α coincides with D^τ, then $P(\mathcal{T}^n, \{Z_\alpha\}, \{G_\alpha\})$ is universal in the class of all those completely regular spaces which admit of a separating mapping of weight τ [cf. A. Zarelua, ibid. 144 (1962), 713–716; MR 26 #5541]; (4) if R is metrizable of weight τ and $\dim R > 0$, then there exists a space S_R and a mapping f of S_R onto R such that S_R is metrizable, $w(S_R) = \tau$, $\dim S_R = 1$, and f is closed, open, compact, 0-dimensional. *M. Katětov* (Prague)

Bothe, H. G. 6470

Ein eindimensionales Kompaktum im E^3, das sich nicht lagetreu in die Mengersche Universalkurve einbetten lässt.
Fund. Math. 54 (1964), 251–258.

The Menger universal curve $U \subset E^3$ [K. Menger, *Kurventheorie*, Teubner, Leipzig, 1932] is a 1-dimensional curve (i.e., continuous image of [0, 1]) in which every 1-dimensional metric space can be embedded. The author describes a 1-dimensional curve $X \subset E^3$ for which there is no homeomorphism $h: E^3 \to E^3$ such that $h(X) \subset U$. Like U, X is constructed by punching holes through a cube, except that knotted holes are used. Apart from classical spadework, the proof is elementary and proceeds by showing that a certain simple closed curve cannot be freed from X via a small homeomorphism of E^3.

Cook, H. 6471

Concerning connected and dense subsets of indecomposable continua.
Fund. Math. 53 (1963), 21–23.

In this paper it is shown that if the continuum hypothesis is true, every compact metric indecomposable continuum M contains a connected point set K, containing no perfect set, such that each component of M contains one and only one point of K. An early result of P. M. Swingle [Bull. Amer. Math. Soc. 37 (1931), 254–258] is used. The paper is well-organized, with the proofs concise.

L. K. Barrett (Knoxville, Tenn.)

Hudson, Anne L. 6472

Note on pointwise periodic semigroups.
Proc. Amer. Math. Soc. 15 (1964), 700–702.

The author calls an element x of a semigroup S periodic if there is a natural number n such that $x^{n+1} = x$. The least

such n is called the period of x and is denoted by $p(x)$. (Since the main result of the paper concerns the notion of the period of an element, it should be remarked that Poole [Amer. J. Math. 59 (1937), 23–32] and others have called an element x periodic if there are positive integers n and ρ such that $x^{n+\rho}=x^{\rho}$. In this case the least n is the period and ρ the index or preperiod.) The author establishes as a corollary the following. Let S be a pointwise periodic semigroup on an n-cell. Then $p(x)\leq 2$ for all x in S. This answers a problem raised by A. D. Wallace [Bull. Amer. Math. Soc. 68 (1962), 447–448]. The result established is that if S is a compact semigroup which is the union of totally disconnected (compact) subgroups and contains a closed set B such that $S-B$ is a connected manifold dense in S and $\dim B<\dim S$, then $p(x)\leq 2$ for all x in S. This is done by invoking results of the reviewer and Anderson [Math. Ann. 147 (1962), 248–268; MR 26 #4324] to first get $\dim S=\dim E$ and then by using a result of Newman on periodic homeomorphisms [Quart. J. Math. Oxford Ser. 2 (1931), 1–8].

Černavskiĭ, A. V. 6475

Isotopy of elements and spheres in n-dimensional space with $k<\frac{1}{2}n-1$. (Russian)

Dokl. Akad. Nauk SSSR 158 (1964), 62–65.

Let E^n be Euclidean n-space. The author establishes the following results. Theorem 1: If $k<\frac{1}{2}n-1$, then every homeomorphism $E^n\to E^n$ is expressible as a composition h_2h_1, where h_1 is stable (in the sense of Morton, Brown and Gluck) and h_2 is the identity on a k-dimensional hyperplane. Theorem 2: If $k<\frac{1}{2}n-1$, then every locally flat embedding of a k-sphere in E^n is isotopic to the embedding of the boundary of a $(k+1)$-simplex, by an isotopy which is constant outside a bounded open set. Theorem 3: If $k<\frac{1}{2}n-1$, then any two locally flat embeddings of a k-simplex in E^n which coincide on the boundary of the simplex are isotopic, by an isotopy which is the identity on the image of the boundary and outside a bounded open set. The author observes that it follows from a classical result of Alexander that Theorem 1 is equivalent to Theorem 1′: If $k<\frac{1}{2}n-1$, then every locally flat embedding of a k-simplex in E^n is isotopic to the standard semilinear embedding by an isotopy which is the identity outside a bounded open set. Theorem 1 is proved by a small generalization of the Stallings-Zeeman engulfing lemma, and Theorems 2 and 3 are then deduced from Theorem 1′ by applying results of Stallings [Ann. of Math. (2) 77 (1963), 490–503; MR 26 #6946].

The author observes that, if $k\leq\frac{1}{2}n-2$, then his results may be deduced from results of Gluck [Bull. Amer. Math. Soc. 69 (1963), 824–831; MR 27 #5241b] and Greathouse [ibid. 69 (1963), 820–823; MR 27 #5241a]. On the other hand, his results lead in turn to the extension of the results of Gluck and Greathouse to the case $k<\frac{1}{2}n-1$.

King, L. R.; Roberts, J. H.; Rosenstein, G. M., Jr. 6476

Concerning some problems raised by A. Lelek.

Fund. Math. 54 (1964), 325–334.

Let C denote a collection of disjoint subsets of Euclidean n-space E^n, let C^* denote the union of the elements of C, and let $A(C)$ denote the set of all points p such that $p=\lim C_i$, where $C_1,C_2,\cdots$ are elements of C. Lelek [Fund. Math. 51 (1962/63), 87–109; MR 26 #1862] defined a "fixation" of C as a set $Z\subset E^n$ which intersects each element of C, and raised some questions about conditions under which C (I) has a 0-dimensional compact fixation, or (II) has an arc as a fixation, or (III) has, for each ϵ, a fixation which is the union of a finite number of disjoint closed sets of diameter less than ϵ. The authors construct two examples in E^2 to give negative answers to the following three of Lelek's questions. (1) Does (I) hold if C^* is bounded and the elements of C are connected sets whose diameters have a positive lower bound? (2) Does (III) imply (I) if C^* is bounded and the elements of C are connected? (3) Does (II) imply (III) if $\dim A(C)\leq 0$ and the elements of C are connected?

C. E. Burgess (Salt Lake City, Utah)

Mazur, Barry 6477

The method of infinite repetition in pure topology. I.

Ann. of Math. (2) 80 (1964), 201–226.

The object of this paper, as stated by the author, is to present the formal aspects of a method of infinite repetition in topology which, in various guises, has already been capitalized on by the author himself [Bull. Amer. Math. Soc. 65 (1959), 59–65; MR 22 #8469], M. Brown [ibid. 66 (1960), 74–76; MR 22 #8470b], M. Morse [ibid. 66 (1960), 113–115; MR 22 #8470a] and J. R. Stallings [ibid. 66 (1960), 485–488; MR 23 #A2214]. Essentially, the method is embedded in a theory of canonical neighborhoods for arbitrary subspaces of arbitrary topological spaces, and standard applications of the method appear as straightforward corollaries in the formal theory. The author plans to apply the theory to obtain his stable homeomorphism theorem [ibid. 67 (1961), 377–384; MR 24 #A557] in a sequel to this paper.

H. R. Gluck (Cambridge, Mass.)

McMillan, D. R., Jr. 6478

The singular points of a topological embedding.
Duke Math. J. **31** (1964), 711–716.

Let Y be a subset of the space X and let $x \in X$. Following the terminology introduced by Eilenberg and Wilder [Amer. J. Math. **64** (1942), 613–622; MR **4**, 87] the author calls Y locally p-connected at x if for each neighborhood U of x there is a neighborhood V of x such that $V \subseteq U$ and each map of S^p in $V-Y$ is null-homotopic in $U-Y$.

In this paper the author strengthens some of his previous work in characterizing open domains of S^n ($n \neq 4$) which are topologically equivalent to E^n by a study of their connectivity—in the above sense—at their boundaries [see Ann. of Math. (2) **79** (1964), 327–337; MR **28** #4528]. He seems to prefer stating his results in terms of embeddings of S^{n-1} in S^n, as may be witnessed by his Theorem 2. Let Σ be a topological $(n-1)$-sphere in S^n, where $n \neq 4$; let K be a component of $S^n - \Sigma$; and suppose that K is locally 1-connected at each point of $\Sigma - X$, where X is a compact subset of Σ. In either of the following cases K is homeomorphic to E^n: (I) If X is countable; (II) If $\Sigma - X$ is 1-connected and for each open set U of S^n such that $\Sigma \subseteq U$, there is an open set V such that $\Sigma \subseteq V \subseteq U$ and each loop in $V - X$ is null-homotopic in $U - X$.

This result is interesting and useful, but the restriction that the boundary of K is an $(n-1)$-sphere seems somewhat artificial since few properties of the sphere are needed to prove the theorem. Apparently if Σ were only an ANR of the homotopy type of S^{n-1} such that $\Sigma - X$ were 1-connected, the result would still hold.

Poénaru, Valentin 6479

Sur quelques propriétés des variétés simplement connexes à trois dimensions.
Rend. Mat. e Appl. (5) **20** (1961), 235–269.

From the author's introduction: "Le présent travail contient les démonstrations des deux propositions suivantes. Théorème 1: Soit V_3 une variété simplement connexe, compacte à trois dimensions, $B_3 \subset V_3$ une cellule à trois dimensions contenue dans V_3. Il existe alors une application localement topologique: $f\colon (V_3 - \operatorname{int} B_3) \to E_3$. Théorème 2: Soit V_3 une variété simplement connexe, compacte à trois dimensions. Il existe alors un nombre positif, entier, $n(V_3)$ tel que si l'on enlève de V_3, $n(V_3)$ cellules à trois dimensions, deux à deux disjointes $B_3{}^1$, $B_3{}^2, \cdots, B_3{}^{n(V_3)}$ on ait:

$$B_2 \times \left(V_3 - \bigcup_1^{n(V_3)} \operatorname{int} B_3{}^i\right) = B_2 \times \left(S_3 - \bigcup_1^{n(V_3)} \operatorname{int} B_3{}^i\right),$$

où S_3 est la sphère à trois dimensions.

"Le théorème 2 a comme corollaire immédiat: Soit V_3 une variété simplement connexe, compacte à trois dimensions. Il existe un entier positif $n(V_3)$ tel que si $P^1, P^2, \cdots, P^{n(V_3)}$ sont des points distincts de V_3:

$$E_2 \times \left(V_3 - \bigcup_1^{n(V_3)} P^i\right) = E_2 \times \left(S_3 - \bigcup_1^{n(V_3)} P^i\right)."$$

Andrásfai, B. 6480

Graphentheoretische Extremalprobleme.
Acta Math. Acad. Sci. Hungar. **15** (1964), 413–438.

The graphs of this paper are without loops or multiple joins. The valency of a vertex p of a graph G is denoted by $\phi_G(p)$, and the least valency in G by $\phi_0(G)$.

The paper is mainly concerned with the following problem. Suppose the number n of vertices of G and the maximum number τ of independent vertices of G are given. Suppose further that k is an integer such that no odd polygon of G has fewer than $2k+1$ vertices. What is the greatest possible value of $\phi_0(G)$, and for what graphs is it attained?

The case $\tau/n \geq \frac{1}{2}$ is solved easily; $\phi_0(G) \leq n - \tau$, and the equality holds for the complete bipartite graph with τ vertices in one class and $n-\tau$ in the other. The main result of the paper deals with the interval $k/(2k+1) \leq \tau/n < \frac{1}{2}$ and is as follows. Write $n = 2\tau + \delta$. Then if k is even, $(3k+2)\phi_0(G) \leq 6\tau + 4\delta$, and if k is odd, $(k+1)\phi_0(G) \leq 2\tau + 2\delta$. Moreover, the stated upper bound for $\phi_0(G)$ can be attained whenever it is an integer.

The last section of the paper is an interesting survey of some related results and conjectures.

Andreatta, Antonio 6481

Alcuni sviluppi sulla teoria relativa dei singrammi finiti.
Ann. Mat. Pura Appl. (4) **65** (1964), 1–25.

The author investigates the embedding of a graph on a surface, which may be orientable or non-orientable. It is shown that each such embedded graph is obtainable from a cubic graph with a Hamilton circuit lying on the same surface. This leads to a new proof of the Kuratowski criterion for planar graph and also a criterion for a cubic graph with Hamilton circuit to be embeddable in the projective plane.

O. Ore (New Haven, Conn.)

Dirac, G. A. 6482

Valency-variety and chromatic number of abstract graphs.
Wiss. Z. Martin-Luther-Univ. Halle-Wittenberg Math.-Natur. Reihe **13** (1964), 59–63.

In this paper the symbol $\langle k \rangle$ denotes a complete k-graph, and $\Phi(c)$ denotes the join of a pentagon to a $\langle c-3 \rangle$. The valency-variety of a finite graph Γ is the number of different valencies occurring in it. The author studies the relation between the valency-variety w, the total number n of vertices and the chromatic number k of Γ. He finds that $k \leq n - [\frac{1}{2}w]$, equality being possible whenever $n \geq 2$ and $1 \leq w \leq n-1$. If Γ contains no $\langle n - [\frac{1}{2}w] \rangle$, then $k \leq n - [\frac{1}{2}w] - 1$, and the equality can hold whenever $n \geq 4$ and $2 \leq w \leq n-2$, and whenever n is even, $n \geq 4$ and $w = n-1$. If w is odd and Γ contains no $\langle n - [\frac{1}{2}w] - 1 \rangle$ or $\Phi(n - [\frac{1}{2}w] - 1)$, then $k \leq n - [\frac{1}{2}w] - 2$.

The author also considers a regular graph Γ ($w = 1$) in which the valency v satisfies $3 \leq v \leq n-2$. It is known that $k \leq v+1$ in such a graph, with equality only when Γ contains a $\langle v+1 \rangle$. The author shows that if $[\frac{1}{2}n] \leq v \leq n-3$

and $n \equiv v+1 \bmod 2$, then $k \le \min(v, \frac{1}{2}n)$. For $[\frac{1}{2}n] \le v \le n-4$ and $n \equiv v \bmod 2$ he finds that

$$k \le \min(v, (2n-2v-3)n/(3n-3v-4)).$$

If $v = n-2$, then $k = \frac{1}{2}n$. *W. T. Tutte* (Waterloo, Ont.)

Foster, B. L. 6483

Short proof of a theorem of Rado on graphs.

Proc. Amer. Math. Soc. **15** (1964), 865–866.

Radó's theorem is stated here as follows. Given a locally finite graph (G, Γ), a finite set of integers K, and a mapping T of subsets of K into subsets of K; if each finite subgraph (A, Γ_A) admits a function ϕ_A such that $\phi_A(x) \in T(\phi_A(\Gamma_A x))$ for all $x \in A$, then (G, Γ) admits a function ϕ such that $\phi(x) \subset T(\phi(\Gamma x))$ for all $x \in G$. Here a (directed) graph is defined by a (not necessarily single-valued) mapping Γ of a set G into itself.

The author states that the proof of this theorem in Berge's textbook [C. Berge, *Théorie des graphes et ses applications*, deuxième édition, Dunod, Paris, 1963; MR **27** #5246] suffers from inaccuracies. He offers instead a short proof based on König's "Unendlichkeitslemma".

Klee, Victor 6487

A property of d-polyhedral graphs.

J. Math. Mech. **13** (1964), 1039–1042.

A graph is d-polyhedral if it is isomorphic to the 1-dimensional skeleton of a d-dimensional convex polytope. It is known that any d-polyhedral graph is d-connected. The author extends this result and applies it.

Given a graph G and two disjoint sets of its nodes, U and V, U is totally separated by V in G if every path joining a pair of nodes of U intersects some node of V. For $n \ge 0$, $\sigma_n(G)$ is the largest integer m for which there is some set of m nodes in G that is totally separated by some set of n nodes in G. Finally, for $n \ge d+1$, let $\mu(d, n)$ be the maximum number of $(d-1)$-faces of a d-polytope with n vertices. The result is this: $\max_G\{\sigma_n(G) | G$ is d-polyhedral$\} = 1$ if $n \le d-1$, $= 2$ if $n = d$, and $= \mu(d, n)$ if $n \ge d+1$. The result is used to show that for every d there exist d-polyhedral graphs that are not e-polyhedral for any $e \ne d$. *M. L. Balinski* (Princeton, N.J.)

Enumeration of paths in digraphs.

Psychometrika **29** (1964), 153–165.

Author's summary: "The solution of the problem of enumeration of the n-paths in a digraph has so far been attempted through an indirect approach of enumerating the redundant chains. The approach has yielded an algorithm for determination of the general formula for the matrix of redundant n-chains and also a partial recurrence formula for the same. This paper presents a direct approach to the problem. It gives a recurrence relation expressing the matrix of n-paths of a digraph in terms of the matrices of $(n-1)$-paths of its first-order subgraphs. The result is exploited to give an algorithm for computing the matrix of n-paths. The algorithm is illustrated with a 6×6 matrix." *G. Sabidussi* (Hamilton, Ont.)

Sabidussi, Gert 6489

Infinite Euler graphs.

Canad. J. Math. **16** (1964), 821–838.

The author studies infinite Euler graphs, that is, graphs whose local degrees are even or infinite. It is shown that a graph is an Euler graph if and only if it has an edge-disjoint covering by means of finite or infinite circuits, generalising a result by Veblen for finite graphs. The paper also contains criteria for an Euler graph to be coverable by finite circuits. *O. Ore* (New Haven, Conn.)

Cohomologies of a Steenrod algebra. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 1284–1287.

The first three theorems in this paper are concerned with the spectral sequence for extensions of Hopf algebras, similar to some work of Adams [Ann. of Math. (2) **72** (1960), 20–104; MR **25** #4530]. Next, the author announces some results on the cohomology of the Steenrod algebra, as well as applications to stable homotopy groups of spheres. Barratt, Liulevicius, May, and others have made similar calculations, although their work is not yet in print. *D. W. Kahn* (Minneapolis, Minn.)

Hsiang, Wu-yi [Hsiang, Wu-Yi] 6491

On the unknottedness of the fixed point set of differentiable circle group actions on spheres—P. A. Smith conjecture.

Bull. Amer. Math. Soc. **70** (1964), 678–680.

The principal result can be stated without reference directly to knottedness. The assertion is that a differentiable action of S^1 on S^n with an $(n-2)$-dimensional fixed-point set F is equivalent to an orthogonal action if and only if F is an $(n-2)$-sphere for $n > 5$. This implies that if F is S^{n-2}, then this $(n-2)$-sphere is unknotted. An essentially complete argument is presented.

Eckmann, B.; Ganea, T.; Hilton, P. J. 6492

Generalized means.

Studies in mathematical analysis and related topics, pp. 82–92. Stanford Univ. Press, Stanford, Calif., 1962.

A mapping $f: X^n \to X$, where X^n denotes the n-fold Cartesian product, is called an n-mean if it is symmetric in the variables and satisfies $f(x, x, x, \cdots, x) = x$. Such means have been studied by Aumann and Carathéodory [cf. Aumann, Math. Ann. **119** (1944), 210–215; MR **6**, 277] and by Eckmann [Comment. Math. Helv. **28** (1954), 329–340; MR **16**, 503]. Eckmann showed, among other things, that an n-mean of a space is carried over, in an appropriate way, to its homotopy groups. The present paper places the study in a category-theoretic framework. The authors make an appropriate definition of an object with n-mean within the context of a category in which direct products exist. Among the categories considered are $\mathscr{G}$—that of groups and homomorphisms, $\mathscr{A}$—that of abelian groups and homomorphisms, $\mathscr{T}_h$—that of based spaces (of the based homotopy type of polyhedra) and based homotopy classes. Having made appropriate definitions and having shown that a covariant D-functor preserves means, the authors obtain results having as corollaries the following. If $A \in \mathscr{T}_h$ admits an n-mean, then so does A^X, ΩA, the loop space on A, and $\tilde{A}$, the universal covering space of A. If $A \in \mathscr{T}_h$ admits an n-co-mean, then A^X admits an n-mean (for any X).

After considering notions of primitivity and their connections with means and co-means, the authors note that the only objects with an n-co-mean in $\mathscr{G}$, where $n \geq 2$, are the trivial groups. Assuming the spaces considered to be connected and to have the based homotopy type of polyhedra, they show that if $A \in \mathscr{T}$ admits an n-mean, then it admits the structure of a homotopy commutative H-space. It follows that if $n \geq 2$ and $A \in \mathscr{T}$ has the homotopy type of a polyhedron, then A admits a homotopy n-mean if and only if it is contractible. (As was shown by Eckmann, an indecomposable continuum such as the n-adic solenoid may admit an n-mean. Another example of a continuum with n-mean would be any compact connected semi-lattice.)

There are a number of results on n-co-means, contractibility and H'-spaces.

A notion of means in groups, not necessarily abelian, was considered by Scott [Amer. J. Math. **74** (1952), 667–675; MR **13**, 910] and B. H. Neumann [J. London Math. Soc. **38** (1963), 226–227; MR **28** #137].

R. P. Hunter (State College, Pa.)

Brooks, Edgar 6493

Homotopy groups of compact Abelian groups.

Proc. Amer. Math. Soc. **15** (1964), 878–881.

The author computes the homotopy groups of an arbitrary compact abelian group. Let G be such a group. Then $\pi_n(G) = 0$, $n \geq 2$, and $\pi_1(G)$ is isomorphic to $\mathrm{Hom}(G^*, Z)$. Here G^* denotes the Pontrjagin dual of G ($G^* = \mathrm{Hom}(G, T)$, T the group of complex numbers of length 1), and Z is the additive group of integers.

Toda, Hirosi 6494

A survey of homotopy theory. (Japanese)

Sûgaku **15** (1963/64), 141–155.

This survey is a skillful treatise on homotopy theory designed to present some recent developments of the subject, and it consists of a well-organized offering of materials and results.

To begin with, the author comments briefly on three main streams of methods in homotopy theory to be called, say, constructive, cohomological and differentio-topological, respectively, along which the contents of this survey are arranged.

The first half contains some basic notions, such as the homotopy set functors, the space functors, together with their properties and relations. The author gives various examples of homotopy sets admitting some natural group structures, among which are included the K-groups in the sense of Grothendieck, Atiyah and Hirzebruch, and also several exact sequences of importance concerning the above groups.

The second half deals with various types of operations. The operations of cohomotopy type $\Psi: \pi(\ , Y) \to \pi(\ , Y')$ are of special importance, and give, as examples, the usual cohomology operations, the generalized Hopf invariants, the Chern character and the operations in the K-theory. The operation of the second kind is defined as the secondary composition (the so-called Toda bracket). An example is called a functional Chern character, which gives rise to an interesting invariant

$$CH^{n+k}: \pi_{2n+2k-1}(S^{2n}) \to Q/Z.$$

This invariant is closely related to a work of Adams and Dyer.

The last section is for applications and contains the following: a brief indication of the composition method to calculate the homotopy groups of spheres, some topics on the invariant CH^{n+k}, some results on the unstable homotopy groups of unitary groups and on the stable homotopy groups of Moore spaces.

Mimura, Mamoru; Toda, Hirosi 6495a

Homotopy groups of SU(3), SU(4) and Sp(2).

J. Math. Kyoto Univ. **3** (1963/64), 217–250.

Mimura, Mamoru; Toda, Hirosi 6495b

Homotopy groups of symplectic groups.

J. Math. Kyoto Univ. **3** (1963/64), 251–273.

These are two papers of a series planned by the authors on the homotopy of the simple groups.

In the first paper they compile π_i, $G = SU(3)$, $SU(4)$ or $Sp(2)$ up to $i = 23$.

In the second one they study the almost stable groups $\pi_i(\mathrm{Sp}(n))$, $i=4n+2, 4n+3, 4n+4$. Their result here is that

$$\begin{aligned}\pi_{4n+2} &= \mathbf{Z}_{2(2n+1)!}, && n \text{ odd},\\ &= \mathbf{Z}_{(2n+1)!}, && n \text{ even},\\ \pi_{4n+3} &= \mathbf{Z}_2,\\ \pi_{4n+4} &= \mathbf{Z}_2, && n \text{ odd},\\ &= \mathbf{Z}_2+\mathbf{Z}_2, && n \text{ even}.\end{aligned}$$

R. Bott (Cambridge, Mass.)

Porter, Gerald J. 6496

Homotopical nilpotence of S^3.

Proc. Amer. Math. Soc. **15** (1964), 681–682.

The homotopical nilpotence of S^3 (the group of unit quaternions) is shown to be 4. According to Samelson, one has to prove that $[[j,j],j]\neq 0$, $[[[j,j],j],j]=0$, where j is a generator of $\pi_4(Q)$, and $Q=B_{S^3}$, the infinite quaternionic projective space. This is deduced from results of Hilton on iterated Whitehead products in S^4.

Anderson, Peter G. 6497

Cobordism classes of squares of orientable manifolds.

Bull. Amer. Math. Soc. **70** (1964), 818–819.

Theorem: For every orientable manifold N there exists a spin manifold N which is cobordant to $M\times M$ mod 2, i.e., $[N]=[M\times M]\in\mathfrak{N}$. No full proof is given, but there are indications as follows: By a certain algebraic-geometric procedure applied to projective spaces, a family of manifolds V is constructed. With ground field $\mathbf{R}$ one gets manifolds $V_{\mathbf{R}}$, with $\mathbf{C}$ one gets $V_{\mathbf{C}}$, and comparison of Stiefel-Whitney numbers shows $[V_{\mathbf{C}}]=[V_{\mathbf{R}}\times V_{\mathbf{R}}]$. The $V_{\mathbf{C}}$ turn out to be spin manifolds, and among the $V_{\mathbf{R}}$ generators are found for $\mathrm{Im}(\Omega\to\mathfrak{N})$.

Golo, V. L. 6499

Smooth structures on manifolds with boundary. (Russian)

Dokl. Akad. Nauk SSSR **157** (1964), 22–25.

Continuing the work of W. Browder [Colloq. Algebraic Topology, 1962, Mat. Inst., Aarhus Univ., Aarhus, 1962; MR 26 #3565] and S. P. Novikov [Dokl. Akad. Nauk SSSR 143 (1962), 1046–1049; MR 25 #1628; Izv. Akad. Nauk SSSR Ser. Mat. 28 (1964), 365–474; MR 28 #5445], the author studies problems of equivalence for manifolds with boundary. Let $W=W^n$ be a smooth n-manifold (always 1-connected) with boundary ∂W (also 1-connected). Let T_W and $T_{\partial W}$ be the Thom spaces. Define $A\in\pi_{N+n}(T_W, T_{\partial W})$ by setting $\alpha\in A$ if there is a smooth map $f:(D^{N+n}, S^{N+n-1})\to(T_W, T_{\partial W})$, N large, representing α, which is t-regular on W and a diffeomorphism on $f^{-1}(\partial W)$. Let π^+ be the homotopy classes of maps $F:(W,\partial W)\to(W,\partial W)$ which are represented by maps which, when restricted to the boundary, are diffeomorphisms of degree 1 such that $F^*\nu_W=\nu_W$ (ν_W is the normal bundle). Also define $\pi_{SO}=\pi(W, SO_N)$. The author then announces the following results. π_{SO} operates on A with factor space B. π^+ operates on B. (1) If $n\not\equiv 2 \pmod 4$, B/π^+ may be put into 1-1 correspondence with the set of smooth manifolds, which are homotopically equivalent to $(W,\partial W)$ by a map which respects normal bundles and is a diffeomorphism of degree 1 on ∂W, divided into equivalence classes via diffeomorphisms of degree 1. (2) If $n\equiv 2 \pmod 4$, B/π^+ contains a subset in 1-1 correspondence with the set of such manifolds equivalent under diffeomorphism. The author also announces the following theorem: If W with boundary ∂W is such that

$$H_{4k}(W)\otimes Q=0 \quad \text{for } k=1,2,\cdots,$$

then the set of classes of smooth manifolds with boundary ∂W, which are equivalent under diffeomorphism and which satisfy the condition that the pair of the manifold and boundary are homotopy equivalent to $(W,\partial W)$ by a map which is a diffeomorphism of degree 1 on the boundary, is finite.

The methods indicated include Morse theory, results of Smale, and Bott periodicity for $B_{SO(N)}$. An interesting fact arises as a lemma. While a generalization of the Hirzebruch index theorem to manifolds with boundary appears to be unknown, the author generalizes the proposition that cobordant manifolds have the same index to manifolds with boundary. The author excludes manifolds W^n with $n<7$ or $n=14$ at the beginning.

Wall, C. T. C. 6500

Cobordism of combinatorial n-manifolds for $n\leq 8$.

Proc. Cambridge Philos. Soc. **60** (1964), 807–811.

L'auteur compare les groupes de cobordisme orienté Ω_n^d et Ω_n^c [non orienté $\mathfrak{N}_n^d$ et $\mathfrak{N}_n^c$] des variétés différentiables et combinatoires de dimension n. Il remarque tout d'abord que les théorèmes de triangulation de J. H. C. Whitehead permettent de définir des homomorphismes $T_n:\mathfrak{N}_n^d\to\mathfrak{N}_n^c$ et $U_n:\Omega_n^d\to\Omega_n^c$ qui sont en fait injectifs, puisque les nombres de Stiefel-Whitney et de Pontrjagin déterminent complètement Ω_n^d et $\mathfrak{N}_n^c$ et peuvent aussi se définir dans le cas combinatoire.

L'auteur démontre alors que: (a) pour $n\leq 7$, T_n et U_n sont des isomorphismes, (b) $\Omega_8^c=\mathbf{Z}+\mathbf{Z}+\mathbf{Z}_4$ et le rang de $\mathfrak{N}_8^c$ est 6; les nombres de Stiefel et de Pontrjagin ne déterminent pas ces deux groupes. L'affirmation (a) découle du fait que les théorèmes de lissage des variétés combinatoires donnent des obstructions dans les groupes Γ_i des structures différentiables sur les sphères S^i et que $\Gamma_i=0$ pour $i<7$. Un des points importants de la démonstration de (b) est l'existence d'un homomorphisme C_n de Γ_{n-1} dans Ω_n^c/Ω_n^d défini comme suite. Toute sphère

d'homotopie de dimension $n-1$ borde une variété différentiable; on obtient une variété combinatoire en lui collant un n-disque le long de son bord. Les théorèmes de lissage montrent que C_8 est un isomorphisme. Pour déterminer $R_8{}^c$ l'auteur utilise des suites exactes qu'il a établies dans un travail précédent [Ann. of Math. (2) 77 (1963), 1–15; MR 26 #3072]. *A. Haefliger* (Geneva)

Reinhart, Bruce L. 6501

Cobordism and foliations.

Ann. Inst. Fourier (Grenoble) **14** (1964), *fasc.* 1, 49–52.

L'auteur discute certaines relations de cobordisme associées aux feuilletages de codimension un. Il obtient en particulier une relation entre des classes caractéristiques des feuilles compactes d'un feuilletage de codimension un sur une variété V, lorsque leur nombre dépasse le premier nombre de Betti de V.

A. Haefliger (Geneva)

Ise, Mikio 6502

Generalized automorphic forms and certain holomorphic vector bundles.

Amer. J. Math. **86** (1964), 70–108.

Let $X=G/K$ be a bounded symmetric domain, where G is a semi-simple Lie group whose complexification G_c is simply connected and K is a maximal compact subgroup of G. Let Γ be a discrete subgroup of G which acts freely on X and has a compact fundamental set, and ρ an irreducible representation of K. This paper studies the dimension of the space $H(\Gamma,\rho)$ of holomorphic cross-sections of the complex vector bundle E_ρ on X associated to ρ, which are invariant under Γ. This space may be identified with a space of automorphic forms, and also with the 0th cohomology group $H^0(Y,\mathbf{E}_\rho)$ of $Y=\Gamma\backslash X$ with coefficients in the sheaf $\mathbf{E}_\rho$ of germs of holomorphic cross-sections of the bundle on Y canonically associated to ρ. To study it, the author introduces the bundle $E_\rho{}^*$ associated to ρ on $X^*=G^*/K$, where G^* is a maximal compact subgroup of G_c. Generalizing Hirzebruch's proportionality argument [Internat. Sympos. on Algebraic Topology, pp. 129–144, Univ. Nac. Autónoma de México, Mexico City, 1958; MR 21 #2058], he first shows that $\chi(X,\mathbf{E}_\rho)=\chi(Y)\cdot\chi(X^*,\mathbf{E}_\rho{}^*)$, where $\chi(Y)$ is the arithmetic genus of Y and the other terms are the usual Euler characteristics. The groups $H^i(X^*,\mathbf{E}_\rho{}^*)$ are known from Bott's work on homogeneous vector bundles [Ann. of Math. (2) 66 (1957), 203–248; MR 19, 681], and $\chi(Y)$ is discussed by Hirzebruch [loc. cit.; also Seminars on Analytic Functions, Vol. 2, pp. 92–104, Institute for Advanced Study, Princeton Univ. Press, Princeton, N.J., 1957]; there remains therefore the problem of giving a sufficient condition under which the groups $H^i(Y,\mathbf{E}_\rho)$ vanish for $i\geq 1$. The quotient G/T, where T is a maximal torus of K, can be viewed in a natural manner as the total space of a complex analytic fibre bundle over X with fibre K/T. A spectral sequence argument and Bott's results [loc. cit.] imply that $H^i(Y,\mathbf{E}_\rho)\simeq H^i(\Gamma\backslash G/T,\mathbf{F}_\sigma)$, where $\mathbf{F}_\sigma$ is the line bundle associated to the highest weight σ of ρ (for a suitable ordering of the roots). After a discussion of some differential forms, it is then shown that $\mathbf{F}_\sigma$ is positive if σ satisfies certain conditions. [Reviewer's remark: By a completely different method, Langlands [Amer. J. Math. 85 (1963), 99–125; MR 27 #6386] has obtained a formula for $\dim H(\Gamma,\rho)$ under a slightly more restrictive condition for ρ, but allowing elements of Γ to have fixed points.]

A. Borel (Princeton, N.J.)

Andreotti, A.; Vesentini, E. 6503

On deformations of discontinuous groups.

Acta Math. **112** (1964), 249–298.

Let V and M be C^∞ manifolds and let ψ be a C^∞ map of V onto M. The triple (V,ψ,M) is called a C^∞ family of complex manifolds if (1) ψ is of maximal rank at each point, (2) for every point $x\in V$ there exists a neighborhood W [respectively, U] of x [$\psi(x)$] in V [M], an open set S in $\mathbf{C}^n$ and a diffeomorphism $\varphi: U\times S\to W$ such that (α) $\mathrm{pr}_U=\psi\circ\varphi$, ($\beta$) if $\varphi_i: U_i\times S_i\to W_i$ $(i=1,2)$ are any two such diffeomorphisms, then $\varphi_2{}^{-1}\circ\varphi_1$ is an isomorphism of $\varphi_1{}^{-1}(W_1\cap W_2)$ and $\varphi_2{}^{-1}(W_1\cap W_2)$ endowed with the structural sheaves of germs of C^∞ functions holomorphic on the fibers of the projection pr_{U_i} $(i=1,2)$. It follows then that for every $t\in M$, $\psi^{-1}(t)=X_t$ has a natural structure of a complex manifold. Such a family (V,ψ,M) is called a C^∞ deformation of a complex manifold X_0 if we are given $m_0\in M$ and an isomorphism $j: X_0\to\psi^{-1}(m_0)$. Analogously, we define a holomorphic deformation. Following Kodaira and Spencer [Ann. of Math. (2) 67 (1958), 328–466; MR 22 #3009], we define equivalent deformations, locally equivalent deformations, trivial deformations, etc. A C^∞ deformation (V,ψ,M) of X_0 is called rigid at infinity if we can find a compact set $K_0\subset X_0$ and an isomorphism g of $(X_0-K_0)\times M$ onto an open subset of V such that (1) $\psi\circ g=\mathrm{pr}_M$, (2) $\psi|(V-\mathrm{Im}(g))$ is a proper map. Let (V,ψ,M) be a C^∞ family of complex manifolds, and let $\pi:\tilde V\to V$ be the universal covering manifold of V. Then $(\tilde V,\psi\circ\pi,M)$ is a C^∞ family of complex manifolds. The authors say that (V,ψ,M) is a family of uniformizable structures on a complex manifold D_0 if we can find an isomorphism $\sigma:\tilde V\to D_0\times M$ such that $\psi\circ\pi=\mathrm{pr}_M\circ\sigma$. The authors prove the following rigidity theorem for a C^∞ deformation of a complex manifold satisfying the pseudo-concavity introduced by Andreotti and Grauert [Bull. Soc. Math. France 90 (1962), 193–259; MR 27 #343]. Theorem: Let M be the unit open ball in $\mathbf{R}^m$ and (V,ψ,M) a C^∞ deformation of a complex manifold $X_0=\psi^{-1}(0)$ such that (a) (V,ψ,M) is a family of uniformizable structures on a bounded symmetric domain D whose irreducible components are of $\dim_{\mathbf{C}}>1$, (b) (V,ψ,M) is rigid at infinity, (c) X_0 is connected and strongly q-pseudoconcave with $0\leq q\leq\dim_{\mathbf{C}}X_0-2$, and (d) the fundamental group $\pi_1(X_0)$ is finitely generated. Then (V,ψ,M) is trivial. The proof is based on (I) the W-ellipticity (which will not be explained here) of the tangent bundle of D/Γ, where Γ is a properly discontinuous group acting on D without fixed points (Theorem 4), and (II) the fact that if D/Γ is strongly pseudoconcave, then there exists a relatively compact open set $B\subset D/\Gamma$ whose inverse image in D has D as an envelope of holomorphy (Theorem 1). As a corollary of the rigidity theorem, using an unpublished result of A. Borel, the authors assert that there exist, for D as above, only trivial families of discontinuous groups Γ containing the arithmetic group Γ_1 and keeping the part at infinity of D/Γ rigid. On the other hand, the authors prove that any holomorphic family of complex manifolds uniformizable on a bounded (not necessarily symmetric) domain in $\mathbf{C}^n$

is locally trivial (Theorem 2), i.e., holomorphic deformations and C^∞ deformations behave quite differently.

Morgenstern, Dietrich 6504

★**Einführung in die Wahrscheinlichkeitsrechnung und mathematische Statistik.**

Die Grundlehren der Mathematischen Wissenschaften, Band 124.

Springer-Verlag, Berlin-Göttingen-Heidelberg, 1964. x + 224 *pp.* *DM* 34.50.

Das vorliegende Buch ist aus Vorlesungen entstanden, die der Autor an mehreren deutschen Universitäten gehalten hat. Teilweise ist der Vorlesungscharakter noch erhalten geblieben: Das Buch ist lebhaft und pädagogisch geschickt geschrieben. Es werden nur verhältnismässig geringe Vorkenntnisse verlangt "sodass die Darstellung auch Ingenieuren und Interessenten aus den Wirtschaftswissenschaften zugänglich sein sollte. Die Darstellung ist mathematisch vollständig, indem alle Sätze bewiesen werden, auch wenn die Regularitätsvoraussetzungen weggelassen werden" (aus dem Vorwort). Dieser Zielsetzung kommt vielleicht Gnedenkos Buch [*Lehrbuch der Wahrscheinlichkeitsrechnung*, Akademie-Verlag, Berlin, 1962; siehe #6505] am nachsten, doch ist die mathematische Statistik hier viel stärker betont als bei Gnedenko. Im ersten Teil beschränkt sich der Autor auf diskrete Verteilungen und erst im zweiten Teil beschäftigt er sich mit stetigen Verteilungen, welche Verteilungsdichten besitzen. Im Grossen und Ganzen enthält das Buch Standard-Material, doch müssen einige hübsche und originelle Ideen hervorgehoben werden. So wird der Normierungsfaktor im Satz von Laplace ohne Benützung der Stirling'schen Formel mittels der Čebyšev'schen Ungleichung bestimmt. Weiters sei der kurze Beweis des Satzes von Cramér und Wold ohne Benützung der Fourier-Transformierten erwähnt. Dieser Satz wird übrigens mit Recht nach Radon benannt. Geschickt wird dieser Satz zur Definition der mehrdimensionalen Normalverteilung und der Herleitung ihrer wichtigsten Eigenschaften herangezogen. Schliesslich erwähnen wir noch die Beweisanordnung für den Satz von Kolmogoroff über die Verschärfung des Hauptsatzes der Statistik.

Leider enthält das Buch eine Unzahl von kleineren und grösseren Druckfehlern. Der Referent hat nur wenige druckfehlerfreie Seiten gefunden. Manche dieser Druckfehler sind sinnstörend, zum Beispiel bei der Formulierung der Ungleichung von Kolmogoroff (S. 103) und bei der Definition der Konsistenz (S. 62). In der Terminologie ist der Autor inkonsequent. So wird auf Seite 158 zwischen positiv definit und eigentlich positiv definit unterschieden, auf Seite 175 wird aber dann positiv semidefinit benützt.

Auch wenn man auf Angabe der Regularitätsbedingungen verzichtet, müsste man bei den Sätzen von Gnedenko und Kolmogoroff auf die Bedeutung der Stetigkeit der Verteilungsfunction hinweisen. Die Konsistenzaussagen über die Maximum-Likelihood Schätzungen sollten angesichts der bekannten Beispiele von Le Cam, Bahadur und anderen vorsichtiger formuliert werden. Die Effizienz Aussagen berücksichtigen nicht das Phänomen der Super-Effizienz. In der Form der Literaturzitate ist ebenfalls kein System zu erkennen.

Trotz dieser Kritik soll jedoch diesem Werk das Interesse nicht abgesprochen werden. Der Leserkreis, an den es sich hauptsächlich wendet, wird vieles von der Lektüre profitieren, wozu auch die vielen Übungsaufgaben beitragen werden.

★**Lehrbuch der Wahrscheinlichkeitsrechnung.**

Vom Autor neubearbeitete und autorisierte Ausgabe in deutscher Sprache herausgegeben von Hans-Joachim Rossberg. Dritte erweiterte Auflage.

Akademie-Verlag, Berlin, 1962. xiii + 393 *pp.* *DM* 29.50.

Two mistakes in this third German edition should be corrected in any future edition since they are rather subtle at the level of the book. One is in the proof of Satz 3 on p. 255, where the conclusion (5) cannot be drawn on the basis of the uniform convergence of $\varphi^{(k)}$ and the choice of the "Hauptwert" alone without a further argument. One of the ways of rectifying this is given in Loève [*Probability theory*, p. 297, Van Nostrand, Toronto, 1955; MR 16, 598]. The other mistake occurs on p. 279, where neither the statement nor the proof of a well-known proposition makes sense as given. It would be an instructive exercise for the reader to analyze the fallacy there. {The same mistakes are in the second English translation [Chelsea, New York, 1962] of the original Russian version which appeared in 1961 [MR 25 #2622].}

Rend. Mat. e Appl. (5) **23** (1964), 147–155.

The paper refers to the theory of random partitions of the interval [0, 1] obtained by the successive introduction of random points (a point to any moment $t = 1, 2, \cdots$), and especially to some problems treated by B. de Finetti. The author deals particularly with the probability of conservation of the minimum or of the maximum interval by one or more successive introductions of random points. *O. Onicescu* (Bucharest)

Richards, Paul I. 6512

Averages for polygons formed by random lines.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 1160–1164.

New results are given for averages over the set of all polygons formed by a uniform isotropic Poisson field of straight lines in a plane. The average of a function of the distance between two points independently and uniformly chosen inside such a polygon is found, and by specialisation of the function many particular results are obtained. *P. A. P. Moran* (Canberra)

About a generalized stochastic problem of Laplace.

Rend. Sem. Fac. Sci. Univ. Cagliari **33** (1963), 112–116.

The urn scheme of Laplace which leads to the law of succession is discussed in somewhat more generality and detail than in Feller's book [*Introduction to probability theory and its applications*, Vol. I, second edition, pp. 113–114, Wiley, New York, 1957; MR **19**, 466]. *J. W. Lamperti* (Hanover, N.H.)

Castoldi, Luigi 6514

A continuous analogon of Poisson's distribution. (Italian summary)

Rend. Sem. Fac. Sci. Univ. Cagliari **33** (1963), 245–249.

The author proposes, as a "continuous analogue of Poisson's distribution", the distribution with density $e^{-\lambda}\lambda^x/\Gamma(x+1)$ for $x > 0$ and the remaining mass concentrated at the origin. *J. W. Lamperti* (Hanover, N.H.)

Čencov, N. N. 6515

Geometry of the "manifold" of a probability distribution. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 543–546.

Let H denote the set of probability measures P on a measurable space $(\Omega, \mathcal{S})$, which are absolutely continuous with respect to a measure μ. The author defines a differential geometry in H, in which the geodesic line passing through two "points" P_0 and P_1 is the set of measures P_t $(0 \leq t \leq 1)$ such that

$$(1) \qquad \frac{dP_t}{d\mu} = \frac{1}{b(t)} \left(\frac{dP_0}{d\mu}\right)^{1-t} \left(\frac{dP_1}{d\mu}\right)^t,$$

where $b(t)$ is the normalizing factor

$$(2) \qquad b(t) = \int_\Omega \left(\frac{dP_0}{d\mu}\right)^{1-t} \left(\frac{dP_1}{d\mu}\right)^t d\mu.$$

The measure $I_\alpha(P_0, P_1)$ of order α of the information gain (obtained by replacing the measure P_0 by the measure P_1) is given [see A. Rényi, Proc. Fourth Berkeley Sympos. Math. Statist. and Prob., Vol. I, pp. 547–561, Univ California Press, Berkeley, Calif., 1961; MR **24** #A2410] by

$$(3) \qquad I_\alpha(P_0, P_1) = \frac{\log b(\alpha)}{\alpha - 1} \quad \text{for } 0 < \alpha < 1.$$

Shannon's measure of information is the limiting case for $\alpha \to 1$ of (3):

$$(4) \qquad \lim_{\alpha \to 1} I_\alpha(P_0, P_1) = \int_\Omega \left(\log \frac{dP_1}{dP_0}\right) dP_1 = I_1(P_0, P_1).$$

and Fisher's information is obtained as the limit of $2I_1(P_0, P_t)/t^2$ if P_t tends to P_0 along the geodesic line mentioned.

Thus, all these quantities of information can be interpreted geometrically. *A. Rényi* (Budapest)

Kolmogorov, A. N. 6516

Approximation of distributions of sums of independent terms by infinitely divisible distributions. (Russian)

Trudy Moskov. Mat. Obšč. **12** (1963), 437–451.

Let $F_k(x)$ be the distribution functions of the independent random variables X_k, $k = 1, 2, \cdots, n$, and let $H_n(x)$ be the distribution function of $X = X_1 + X_2 + \cdots + X_n$. Let $E(x)$ be the distribution function of the identically zero random variable, and let $\mathcal{D}$ be the collection of all infinitely divisible distribution functions $\{D(x)\}$.

If the X_k are equi-distributed, $F_k(x) = F(x)$, $k = 1, 2, \cdots, n$, the author proves that there exists a positive constant c_1 such that for at least one element $D \in \mathcal{D}$ one has $|H_n(x) - D(x)| < c_1 n^{-1/3}$ for all x. Let $\rho(F', F'') = \sup_x |F'(x) - F''(x)|$ for two distribution functions F' and F'', and in terms of this metric let $\psi(n) = \sup_F \rho(H_n, \mathcal{D})$. The above theorem implies that $\psi(n) = O(n^{-1/3})$, and this improves an earlier work of the author [Teor. Verojatnost. i Primenen. 1 (1956), 426–436; MR **19**, 586], in which it was proved that $\psi(n) = O(n^{-1/5})$, and of Prohorov [ibid. 5 (1960), 103–113; MR **24** #A2425], who showed that $\psi(n) = O(n^{-1/3} \log^2 n)$. In the other direction Meškin

[ibid. 6 (1961), 257–275; MR 24 #A2963] showed that $\phi(n) \geq c_2 n^{-2/3} \log^{-4} n$.

In the general, non-equidistributed case there is a positive constant c_3 such that whenever the $F_k(x)$ satisfy $E(x-l)-\varepsilon < F_k(x) < E(x+l)+\varepsilon$ for all x, for some $\varepsilon > 0$, $L \geq 2l > 0$, and for $k = 1, 2, \cdots, n$, there exists an element $D \in \mathscr{D}$ such that for all x

$$D(x-L) - \delta \leq H_n(x) \leq D(x+L) + \delta,$$

where $\delta = c_3 \max((l/L)(\log L/l)^{1/2}, \varepsilon^{1/3})$.

D. A. Darling (Ann Arbor, Mich.)

Kubik, L. 6517

On the classes of probability distributions closed under decompositions.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. 12 (1964), 397–403.

According to the author, a subclass $\mathscr{T}$ of $\mathscr{Y}$ of probability distribution functions (non-degenerate) is said to be closed under decompositions in the class $\mathscr{Y}$ if the relation that the distributions of random variables X_1 and X_2 belong to $\mathscr{Y}$, the distribution of X belongs to $\mathscr{T}$ and $X = X_1 + X_2$ (X_1 and X_2 being independent) implies that both distributions of X_1 and X_2 belong to $\mathscr{T}$. This is the generalization of the ordinary closure under decompositions in which $\mathscr{Y}$ is the class of all distribution functions. The author is interested in the case in which $\mathscr{Y}$ is the class of infinitely divisible distributions (i.d.d.) and $\mathscr{T}$ is a subclass of $\mathscr{Y}$, which has the property that for any two distributions of $\mathscr{T}$ which have $G_1(u)$ and $G_2(u)$ for $G(u)$ in the Lévy-Khintchine formula for the logarithm of the characteristic function

$$i\gamma t + \int_{-\infty}^{\infty} \left(e^{itu} - 1 - \frac{itu}{1+u^2}\right) \frac{1+u^2}{u^2}\, dG(u),$$

one has that $G_1(u) = aG_2(u)$ for all u, for some $a > 0$. In this case $\mathscr{T}$ is called a class of distributions of the same sort. The author proves that a class $\mathscr{T}$ of distributions of the same sort closed under decompositions in $\mathscr{Y}$ of i.d.d. is the class of normal distributions or the class of Poisson distributions with characteristic function $\exp(ita + \lambda(e^{itb} - 1))$ with the same value of $b \neq 0$. He also shows that the class $\mathscr{Y}$ of the same sort introduced by him [Studia Math. 21 (1961/62), 245–252; MR 26 #1916] is closed under decompositions in a subclass $\mathscr{S}$ of the class of i.d.d. He also discusses the same problem about the class of stable distributions. *T. Kawata* (Washington, D.C.)

Ladohin, V. I. 6518

On non-positive distributions. (Russian)

Kazan. Gos. Univ. Učen. Zap. 122 (1962), kn. 4, 53–64.

Let Ω be the space of real-valued functions $\omega = \xi(\cdot)$ on $T = [0, \infty)$, H the family of Borel cylinder subsets of Ω, and B the smallest σ-algebra containing H. Suppose that there is given a system of set functions $Q_{t_1 t_2 \cdots t_n}$, $t_1, t_2, \cdots, t_n \in T$, $1 \leq n < \infty$, such that $Q_{t_1 t_2 \cdots t_n}$ is σ-additive and of bounded variation over Borel subsets of R^n, where $Q_{t_1 \cdots t_n}(R^n) = 1$, and the $Q_{t_1 t_2 \cdots t_n}$ jointly satisfy Kolmogorov's consistency conditions. Then a finitely additive set function Q over H is determined. Krylov [Dokl. Akad. Nauk SSSR 132 (1960), 1254–1257; MR 22 #9722] constructed such a Q from the fundamental solution of a parabolic equation of order $q > 2$ and deduced a formula of the Feynman-Kac type. The present author shows that although Q cannot be extended to be σ-additive over B, an analogy to the Markov process theory enables one to deduce a known expansion theorem connected with the Feynman-Kac theorem. *G. Maruyama* (Fukuoka)

Iosifescu, Marius 6522

Sur la loi forte des grands nombres pour les systèmes aléatoires homogènes à liaisons complètes à un ensemble quelconque d'états.

C. R. Acad. Sci. Paris 258 (1964), 4421–4423.

For each s in S, $P(s)$ is a p-measure on X and, for each

x in X, $u(x)$ is a mapping of S into S. $P_m^{(n)}$ denotes the distribution of $x_{n+1}, \cdots, x_{n+m}$ when the distribution of x_i, given $x_1, \cdots, x_{i-1}$, is $P(s_i)$, with $s_{i+1} = u(x_i)$ for $i = 1, 2, \cdots$. If there are distributions P_m with

$$\sum n \sup_{s_1, m} \| P_m^{(n)} - P_m \| < \infty,$$

then certain analogues of the theorems of de Moivre-Laplace, Borel-Cantelli, and V. I. Glivenko hold. Proofs will be published in Rev. Roumaine Math. Pures Appl.

James Hannan (E. Lansing, Mich.)

Keilson, J.; Wishart, D. M. G. 6523

A central limit theorem for processes defined on a finite Markov chain.

Proc. Cambridge Philos. Soc. **60** (1964), 547–567.

Let $\mathbf{B}(x) = \{B_{rs}(x)\}$ be for each x an $m \times m$ substochastic matrix, such that $\mathbf{B}(+\infty)$ is stochastic, irreducible, aperiodic, and such that each element of it is positive and monotone non-decreasing in $-\infty < x < +\infty$. The authors consider a vector process $\{R(n), X(n)\}$ ($n = 1, 2, \cdots$; $R(n) = 1, 2, \cdots, m$; $-\infty < X(n) < +\infty$) whose evolution is determined as follows. Let $\mathbf{F}_n(x)$ be a row vector of m components whose rth component is $\Pr\{R(n) = r, X(n) < x\}$ and determine transition probabilities by $\mathbf{F}_{n+1}(x) = \int \mathbf{F}_n(x-y)\mathbf{B}(dy)$. Assuming that each element of the matrix $\int y^2 \mathbf{B}(dy)$ is finite, the authors prove that

$$\lim_{n\to\infty} \mathbf{F}_n(x\sqrt{n} + \mu n, n) = \Phi(x\sigma^{-1})\mathbf{e},$$

where $\Phi(x)$ is the standard normal distribution, μ and σ^2 are constants associated with the first two moments of $\mathbf{B}$, and where $\mathbf{e}$ is the vector satisfying $\mathbf{eB}(+\infty) = \mathbf{e}$. The theorem also shows that $X(n)$ and $R(n)$ are asymptotically independent.

Assuming the entries in the matrix of Fourier transforms $\hat{\mathbf{B}}(z) = \int \exp(izy)\mathbf{B}(dy)$ have a common strip of convergence, there is a "conjugate process" $\{\hat{R}(n), \hat{X}(n)\}$ which permits a discussion of the asymptotic behavior of $\mathbf{F}_n(x)$ near the tails.

Extensions are given to the case when $\mathbf{B}(+\infty)$ is irreducible but not necessarily aperiodic, and to the corresponding process in continuous time.

Petrov, V. V. 6525

Limit theorems for large deviations violating Cramér's condition. II. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), *no.* 1, 58–75.

This paper continues the author's previous work [same Vestnik **18** (1963), no. 4, 49–68; MR **28** #1646] on limit theorems for large deviations without assumption of Cramér's condition. There are eight theorems which are partly generalizations of results obtained by Linnik. The theorems are too complicated to be stated here in detail.

J. E. Cigler (Groningen)

Rjauba, B. 6526

The central limit theorem for sums of series of weakly dependent random variables. (Russian. Lithuanian and English summaries)

Litovsk. Mat. Sb. **2** (1962), *no.* 2, 193–205.

Let $\{X_1^{(n)}, \cdots, X_n^{(n)}, n = 1, 2, \cdots\}$ be a sequence of sets of random variables with finite second moments. If the dependence between the random variables is sufficiently weak in a certain sense, the author shows that the distribution of the sum $(X_1^{(n)} + X_2^{(n)} + \cdots + X_n^{(n)})$, suitably normalized, converges to the normal distribution. The author's sufficient conditions cannot be stated precisely in a short space; they involve various conditional probabilities of "future" events, given the "past".

S. G. Ghurye (Bloomington, Ind.)

Vilkauskas, L. 6527

Two integral theorems on large deviations in the higher-dimensional case. (Russian. Lithuanian and English summaries)

Litovsk. Mat. Sb. **3** (1963), *no.* 2, 53–67.

The integral limit theorem (i.l.t.) is said to hold for a sequence of regions Q_n of s-dimensional space and for a sequence of identically distributed s-dimensional random variables X_n, if $P(X_n \in Q_n)/\Phi(Q_n) \to 1$, where Φ is the standard Gaussian measure in s-dimensional space. In the spirit of Ju. V. Linnik's work on large deviations in one dimension [Teor. Verojatnost. i Primenen. **6** (1961), 145–163; MR **25** #1572; ibid. **6** (1961), 377–391; MR **27** #804] the author first considers the regions $Q_n = \{x \,|\, |x| \gtrsim R_n\}$, where $0 \leq R_n \leq n^\alpha/\rho(n)$, $\rho(n) \to \infty$, $\alpha < \frac{1}{6}$. When the random variables X_n have mean 0 and identity covariance matrix, the s-dimensional analogue of Linnik's condition $\mathrm{E}\exp|X_n|^{4\alpha/(2\alpha+1)} < \infty$ is shown to be sufficient for the i.l.t. to hold. Subsequently the methods are extended to prove the i.l.t. for a larger class of regions Q_n, defined in terms of the asymptotic behavior of their Gaussian measures.

F. L. Spitzer (Ithaca, N.Y.)

Beilinson, A. A. 6528

On the solution of a non-uniform problem in probability for distributed systems. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 519–523.

Author's summary: "A dynamical system is considered which is described by a parabolic equation in a circle of length $2l$ when acted upon by an undistributed stochastic force $f(t)$ (white noise)

$$\frac{\partial W(x,t)}{\partial t} - \frac{\partial^2 W(x,t)}{\partial x^2} = \delta(x) f(t).$$

"The Green's function for this system (a countable additive measure in the phase space) is constructed. This measure is not quasi-invariant. It is proved that almost all profiles $W(x)$ are infinitely differentiable."

J. Chover (Madison, Wis.)

Dudley, R. M. 6529

Singular translates of measures on linear spaces.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **3**, 128–137 (1964).

Let F be the field of real or complex numbers, and let Q be any linear space over F. Let Q^a be the algebraic dual space of Q. For any n-tuple $(q_1, \cdots, q_n)$ of members of Q and Borel set B in n-space F^n, let $S(q_1, \cdots, q_n, B) = \{q' \in Q^a : \langle q'(q_1), \cdots, q'(q_n)\rangle \in B\}$. Let $\mathscr{L}_Q$ be the σ-algebra of subsets of Q^a generated by all such sets. A random linear functional (r.l.f.) on Q is an assignment to each n-tple $(q_1, \cdots, q_n)$ of a Borel probability measure μ on F^n such that for any $q_i, r_j \in Q$ and Borel sets $B \subset F^n$ and $C \subset F^m$, $S(q_1, \cdots, q_n, B) = S(r_1, \cdots, r_m, C)$ implies that $\mu(q_1, \cdots, q_n)(B) = \mu(r_1, \cdots, r_m)(C)$. There is a one-one correspondence between such r.l.f.'s on Q and probability measures P on $\mathscr{L}_Q$ (Theorem 1 reproves this briefly). An r.l.f. μ is called quadratic if $\int_F |x|^2 \mu(q)\,dx < \infty$ for each $q \in Q$. Then its mean

$$m(q) = \int_F x\mu(q)(dx) = \int_{Q^a} q'(q)\,dP(q')$$

is in Q^a. Its covariance

$$B(q, r) = \int_F \int_F x\bar{y}\mu(q, r)(dx, dy) = \int_{Q^a} q'(q)\overline{q'(r)}\,dP(q')$$

defines a topology on Q by the pseudo-norm $\|q\|_P = B(q, q)^{1/2}$. The main result is Theorem 2: If μ is a quadratic r.l.f. corresponding to the measure P on $\mathscr{L}_Q$, and if $z \in Q^a$ is a linear functional on Q which is not continuous in the $\|\ \|_P$ topology, then the measures P and P_z, the translate of P by z, are singular. The proof is brief. The author then applies this result for Q a topological linear space. In particular, when Q is a real Hilbert space he gets a simpler proof of a result of V. N. Sudakov. The author briefly treats the Gaussian case, and also deduces consequences of Theorem 2 for random distributions, and, in particular, stationary ones.

Has'minskii, R. Z. 6530

Diffusion processes with a small parameter. (Russian)

Izv. Akad. Nauk SSSR Ser. Mat. **27** (1963), 1281–1300.

In the present paper the author has studied the asymptotic behavior of some functional of the trajectory of the Markov process $X_\epsilon(t)$ connected with the differential operator

$$L^{(\epsilon)}(x) = \sum_{k=1}^{2} A_k(x)\frac{\partial}{\partial x_k} + V(x) + \epsilon L(x).$$

Here $x = (x_1, x_2)$ denotes the point of the two-dimensional plane and

$$L(x) = \sum_{i,j=1}^{2} a_{ij}(x)\frac{\partial^2 x}{\partial x_i \partial x_j} + \sum_{i=1}^{2} b_i(x)\frac{\partial}{\partial x_i}.$$

Many of the results proven in this paper were already stated by the author [Dokl. Akad. Nauk SSSR **142** (1962), 560–563; MR **26** #477]. *R. G. Laha* (Washington, D.C.)

Kahane, Jean-Pierre 6531

Sur les sommes vectorielles $\sum \pm u_n$.

C. R. Acad. Sci. Paris **259** (1964), 2577–2580.

L'auteur considère la série (1) $V = \sum_1^\infty \varepsilon_n u_n$, où les u_n sont des éléments d'un espace de Banach B, et où les ε_n sont des variables aléatoires de Bernoulli symétriques et indépendantes. Il pose $V_n = \sum_1^n \varepsilon_m u_m$, $S = \sup_n \|V_n\|$. Il démontre les théorèmes suivants. (I) Si (1) est p.s. (presque sûrement) convergente et si $p(\|V\| > r) < \alpha/2$, alors $p(\|V\| > 2r) < \alpha^2$. Si (1) est p.s. bornée et si $p(S > r) < \alpha$, alors $p(S > 2r) < 2\alpha^2$. (II) Soit $T = (a_{nm})$ une matrice telle que $\lim_{n\to\infty} a_{nm} = 1$. Soit $W_n = \sum_{m=1}^\infty a_{nm}\varepsilon_m u_m$. Si W_n existe pour tout n et a une limite dans B [est bornée dans B] quand $n \to +\infty$, on dit que (1) est T-sommable [T-bornée]. Si cette propriété a lieu presque sûrement, la série (1) est p.s. convergente [bornée]. (III) Soit λ_n une suite de nombres complexes tels que $0 \le |\lambda_n| \le 1$. Si (1) est p.s. convergente [bornée], la série $\sum_1^\infty \varepsilon_n \lambda_n u_n$ est p.s. convergente [bornée].

Il en résulte que, si les ω_n sont des variables aléatoires indépendantes équiréparties sur $[0, 1]$, la série (1) et la série $\sum_1^\infty \exp(2i\pi\omega_n)u_n$ sont en même temps p.s. convergentes [bornées]. *J. Bass* (Paris)

Krzyżański, M. 6532

Principe d'extremum relatif aux solutions de l'équation intégro-différentielle du processus stochastique markovien purement discontinu.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **11** (1963), 531–534.

Let A be a Borel set, T_0 a positive number, $\Sigma_0 = (0, T_0) \times A$. The author considers the equation

$$(1)\qquad u_t'(t, x) = p(t, x)\int_A [u(t, z) - u(t, x)]P(t, x, dz),$$

where $p(t, x)$ is a bounded non-negative function on Σ_0 and $P(t, x, dz)$, for $(t, x) \in \Sigma_0$, a probability distribution on A. He shows that every solution $u(t, x)$ of (1), continuous on $[0, T_0] \times A$, is less than a constant M if $u(0, x)$ has this property, and deduces some consequences from this maximum principle. (1) is the Kolmogorov-Feller equation of a purely discontinuous Markov process.

Petr Mandl (Prague)

Lamperti, John 6533

On a class of stochastic processes.

Ann. Math. Statist. **34** (1963), 206–212.

The author studies a stochastic process $\{Y_t\}$ in R^n which can be obtained as a limit, $\lim_{s\to\infty}\{X_{t+s}/f(s)\}$. Here f is a positive function, $\{X_t\}$ is an arbitrary process in R^n, and the convergence is in the sense of convergence of finite-dimensional distributions. He proves that unless $P(Y_t = 0) \equiv 1$, the scaling function f must be $f(s) = e^{\alpha s}M(s)$, where α is real and $M(s)$ is slowly varying as $s \to \infty$. The limiting process then is such that for each fixed u the process $\{Y_{t+u}\}$ has the same finite-dimensional distributions as the process $\{e^{\alpha u}Y_t\}$. Next he assumes that the limiting process is Markovian with stationary transition function, that the state space is R^1, and that Y_t is never 0, and obtains the following additional information about Y_t. For a constant $A > 0$ define $S_t = -1$ if $Y_t < 0$ and $S_t = A$ if $Y_t > 0$. Then S_t is a stationary Markov chain, and for a suitable choice of A the process $\{Y_t\}$ has the same distributions as the process $\{S_t e^{\alpha t} Y\}$, with Y an appropriate position random variable independent of the process $\{S_t\}$. The author also provides converses to these

assertions and gives some discussion of the Markovian situation when the state space is R^n with $n > 1$.

Mandl, Petr 6534

Über die asymptotischen Verteilungen der Erst-Passage-Zeiten.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 475–498. *Publ. House Czech. Acad. Sci., Prague*, 1964.

In this paper first-passage times for one-dimensional diffusion processes are studied. The author considers two cases, diffusion on the real line and on $(0, \infty)$ with a reflecting barrier in 0. Let $P(t, x; E)$ denote the probability that the process assumes some value in E during the time interval $[0, t)$ if it starts at x. It is assumed that for every real-valued twice continuously differentiable function ψ with compact support the function $w(x, t) = \int P(t, x; dy)\psi(y)$ satisfies

$$\frac{\partial}{\partial t} w = \frac{\partial^2}{\partial x^2} w + b(x) \frac{\partial}{\partial x} w.$$

Let $Q(x) = \exp \int_0^x b(s)\, ds$. The author studies the asymptotic behaviour of the probability $F(t, x; Z)$ that the process starting at x assumes values $\geqq Z$ in the time interval $[0, t)$ under various conditions on $Q(x)$.

Shepp, L. A. 6536

The singularity of Gaussian measures in function space.

Proc. Nat. Acad. Sci. U.S.A. **52** (1964), 430–433.

If Ω is the space of all real-valued functions on $[0, T]$, $\mathfrak{B}$ is the σ-field generated by the coordinate functions, and ρ_0, ρ_1 are two real-valued positive definite functions on $[0, T] \times [0, T]$, then two zero mean Gaussian measures μ_0, μ_1 are induced on $\mathfrak{B}$ in the usual way. Jaglom has proved that the Gaussian measures are either mutually singular or equivalent [Proc. Sympos. Time Series Analysis (Brown Univ., 1962), pp. 327–346, Wiley, New York, 1963; MR **26** #5635b]. Using martingale methods, the author proves the following necessary and sufficient condition for singularity. If π is a partition $0 \leqq t_1 \leqq \cdots \leqq t_n \leqq T$ of $[0, T]$, let ρ_i^{π} be the matrix $\{\rho_i(t_j, t_k)\}$. For $0 < \alpha < 1$, let $\rho_\alpha^{\pi} = (1-\alpha)\rho_0^{\pi} + \alpha\rho_1^{\pi}$. Then $\mu_0 \perp \mu_1$ if and only if $\inf_\pi |\rho_0^{\pi}|^{1-\alpha} |\rho_1^{\pi}|^{\alpha} / |\rho_\alpha^{\pi}| = 0$. If ρ_0 and ρ_1 are continuous, then $\inf_\pi$ can be replaced by a sequential limit. A similar theorem holds if mean value functions μ_0 and μ_1 are given.

Takeuchi, Junji 6537

On the sample paths of the symmetric stable processes in spaces.

J. Math. Soc. Japan **16** (1964), 109–127.

The author solves a number of problems concerning the sample functions of symmetric stable processes $x(t)$ of index α, $0 < \alpha \leqq 2$, in N-dimensional space. The first problem concerns the rate of escape to infinity in the transient case, i.e., when $N > \alpha$. A positive non-increasing function $g(t)$ is in the upper [lower] class if $|x(t)| \leqq g(t)t^{1/\alpha}$ for arbitrarily large t with probability one [zero]. It is shown that g is in the upper [lower] class according as the integral of $t^{-1}[g(t)]^{N-\alpha}$ diverges [converges] at infinity. The proof depends on the Borel-Cantelli lemma together with potential-theoretical estimates of hitting probabilities. The second problem concerns the existence of double points. Using results of Blumenthal and Getoor [Illinois J. Math. **4** (1960), 370–375; MR **22** #12610] it is shown that there are infinitely many double points with probability one if $N \leqq 3$ and $N/2 < \alpha \leqq 2$. In all other cases almost every path is free from double points. The final result deals with the N-dimensional Lebesgue measure of the sample path (the set of $x(t)$, $0 \leqq t < \infty$). It is shown to be zero with probability one when $N \geqq \alpha$, and infinite with probability one when $N < \alpha$. All except the case $N = \alpha = 1$ follow easily from the above-mentioned results of Blumenthal and Getoor concerning the Hausdorff measure of the paths; the result as a whole is stated to be a corollary of unpublished work of S. J. Taylor and D. Ray who determined the exact Hausdorff measure.

Takeuchi, Junji 6538

A local asymptotic law for the transient stable process.

Proc. Japan Acad. **40** (1964), 141–144.

The problem solved in the paper reviewed above [#6537] concerning upper and lower classes determining the rate of escape as $t \to \infty$ suggested the present paper which concerns the local behavior as $t \to 0$. When $x(0) = 0$, $\alpha < N$, a positive non-increasing g is in the upper [lower] class according as $|x(t)| \leqq t^{1/\alpha} g(1/t)$ for arbitrarily small positive t with probability one [zero]. The analytic criterion is shown to be exactly the same integral criterion as that established in the previous paper for the case when $t \to \infty$. For Brownian motion this is a well-known consequence of P. Lévy's law of projective invariance ($x(t)/\sqrt{t}$ and $\sqrt{t}\,x(1/t)$ are equivalent processes). No such law is available in general, but the results are those which would follow if $x(t)/t^{1/\alpha}$ and $t^{1/\alpha}x(1/t)$ were equivalent processes. This is not the case. *F. L. Spitzer* (Ithaca, N.Y.)

Tutubalin, V. N. 6539

Compositions of measures on the simplest nilpotent group. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 531–539.

Let G be the group of matrices $g = g(\alpha, \beta, \gamma) = \begin{pmatrix} 1 & \alpha & \gamma \\ 0 & 1 & \beta \\ 0 & 0 & 1 \end{pmatrix}$, α, β, γ real. If μ is a probability measure on G, then α, β, γ can be regarded as random variables. The distance between μ_1 and μ_2 is defined as $\sup_{a,b,c} |(\mu_1 - \mu_2)(\{g : \alpha < a, \beta < b, \gamma < c\})|$. Let μ_1 and μ_2 be such that α, β, γ have variances under either of them. Necessary and sufficient conditions are obtained in order that the distance between the convolutions μ_1^n and μ_2^n should tend to zero as n tends to infinity. Theorem 1: *If α and β have zero means under both distributions, then necessary and sufficient conditions*

are that each of the four quantities α^2, $\alpha\beta$, β^2, γ should have the same expectation under either μ_1 or μ_2. Theorem 2: If one of the means of α or β is different from zero, then necessary and sufficient conditions are that each of the five quantities α, β, α^2, $\alpha\beta$, β^2 should have the same expectation under either μ_1 or μ_2. (There is no condition on γ in the second case.)

Blumenthal, R. M.; Getoor, R. K. 6540

A theorem on stopping times.

Ann. Math. Statist. **35** (1964), 1348–1350.

This note gives, under suitable conditions, a characterization of the Borel field associated with a stopping time T for a strong Markov process. Roughly speaking, the characterization shows that such a field is generated by the random variables of a "stopped process" which agrees with the original one up to time T and remains constant thereafter. *J. W. Lamperti* (Hanover, N.H.)

Molčanov, S. A. 6541

On a problem in the theory of diffusion processes. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 523–528.

Author's summary: "In the paper some Markov processes associated with diffusion processes are discussed. A diffusion process x_t defined on l-dimensional Euclidean space E is considered only at moments when its trajectory belongs to a given set S (a new time is introduced which changes only when the process is in S). If S is a domain with differentiable boundary, the generator $\tilde{\mathfrak{A}}$ of the new process y_t is the same as for x_t at all interior points of S. On the boundary of S non-classical boundary conditions are obtained. These boundary conditions are described in Theorem 1. If S is an $(l-1)$-dimensional surface, we obtain on S a discontinuous process of the Cauchy type. The generator of this process is investigated in Theorem 2."

Nagasawa, Masao 6542

Time reversions of Markov processes.

Nagoya Math. J. **24** (1964), 177–204.

Consider a temporally homogeneous Markov process x and a positive time $T < \infty$. Then the backwards process $x(T-t-0)$ $(0 < t < T)$ is also a temporally homogeneous Markov process if T is a last exit time, as was proved by G. Hunt [Illinois J. Math. **4** (1960), 313–340; MR **23** #A691]; the same is true if T is a killing time, but for constant T the temporal homogeneity is lost. A wider class of times T for which Hunt's result holds under mild technical conditions on the process x is now described: it is the class of all positive Borel functions T of the path, not exceeding the lifetime, such that $T-s=T(w_s^+)$ if either side is positive and $<\infty$, w_s^+ being the shifted path $t\to x(t+s)$. For this class, the backwards transition probabilities depend upon the law of x but not upon T itself. A similar result is proved for the approximate Markov processes of G. Hunt.

Nagasawa, Masao 6543

The adjoint process of a diffusion with reflecting barrier.

Kôdai Math. Sem. Rep. **13** (1961), 235–248.

Let $X(t)$ be a time homogeneous Markov process with state space $\bar{D}$, a compact set in R^n. Under some additional conditions the process $\hat{X}(t)$ obtained by reversing the time direction is also a time homogeneous Markov process. In this case call $\hat{X}$ the adjoint of X. In the present paper the author assumes that $\bar{D}$ is the closure of a domain D with a quite smooth boundary, Bdy D, that X is a diffusion process with infinitesimal generator A, a quite smooth elliptic differential operator, and that the domain of A consists essentially of those functions f in $C^2(\bar{D})$ such that the outer normal derivative of f vanishes on Bdy D. Because of the boundary condition X is called a "reflecting barrier process". He proves that the adjoint process exists in this case, constructs its infinitesimal generator, and shows that the adjoint process is also a reflecting barrier process. For diffusions arising in this way there is another process, $X_{\mathrm{Bdy}\,D}$, called the "process on the boundary". The author considers this also, and shows that (with an obvious notation) $(\hat{X})_{\mathrm{Bdy}\,D}=(X_{\mathrm{Bdy}\,D})^\wedge$.

Existence of diffusions with continuous coefficients.

Mem. Fac. Sci. Kyushu Univ. Ser. A **18** (1964), 89–103.

Es sei B der Raum der reellen beschränkten Baireschen Funktionen auf R^d mit $d \geq 2$. Die Arbeit befaßt sich mit einer auf dem Hille-Yosida'schen Halbgruppentheorem fußenden Konstruktion einer Halbgruppe linearer Transformationen in B und eines Diffusionsprozesses in R^d zu gegebenem Operator $A=\sum_{i,j=1}^d a^{ij}\partial^2/\partial x^i\partial x^j+\sum_{i=1}^d b^i\partial/\partial x^i$ mit überall positiv definiter Matrix (a^{ij}), wenn die Funktionen a^{ij} nur als stetig und die Funktionen b^i als meßbar und auf jeder kompakten Menge beschränkt vorausgesetzt werden. Dies geschieht zunächst lokal in einer Kugel, wobei A durch "glattere" Operatoren approximiert wird. Der so gewonnene Diffusionsprozeß wird dann identifiziert mit dem, den man erhält, wenn man den entsprechenden Prozeß in einer größeren Kugel konstruiert und dann auf die erste Kugel einschränkt. Der Greensche Operator des auf diese Weise global in R^d bestimmten Prozesses bildet dann den Raum C der stetigen und beschränkten Funktionen auf R^d in sich ab, und seine Erzeugende ist eine Einschränkung einer gewissen natürlichen Fortsetzung von A. Sind auch die b^i stetig, so hat die zugehörige Halbgruppe T^t, $0 \leq t < +\infty$, die Eigenschaft: Bei beliebigem $f \in C^2$ mit kompaktem Träger konvergiert $t^{-1}(T^tf-f)$ gleichmäßig auf R^d gegen Af. *K. Krickeberg* (New York)

Vorob'ev, N. N. 6546

On a topologization of the set of interior consistent families of measures. (Russian. English summary)

Teor. Verojatnost. i Primenen. **8** (1963), 444–451.

The author extends to consistent families of interior measures the theorem proved by him and Faddeev earlier [Teor. Verojatnost. i Primenen. **6** (1961), 116–118; MR **27** #779]. The definition of a consistent family in this context is the same as that used by the author earlier [ibid. 7 (1962), 153–169].

Priestley, M. B. 6548

Estimation of the spectral density function in the presence of harmonic components.

J. Roy. Statist. Soc. Ser. B **26** (1964), 123–132.

Let $X_t = Y_t + Z_t$ be a stationary process, where Y_t is a linear process and Z_t is a process of pure harmonic components of the form $Z_t = \sum_{i=1}^k A_i \cos(\omega_i t + \varphi_i)$. Here k and $A_1, \cdots, A_k$ are unknown constants and $\varphi_1, \cdots, \varphi_k$ are independent and uniformly distributed on $[-\pi, \pi]$. The author provides a technique for detecting the presence of such harmonic components and uses this to construct a consistent estimate of the autocovariance function of the Y_t process. Finally he gives a technique which gives a direct estimate of the spectral density of the Y_t process from the sample autocovariance function.

Šmul'jan, Ju. L. 6549

The optimal factoring of non-negative matrix functions. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 382–386.

In der Theorie der stationären n-dimensionalen stochastischen Prozesse mit diskreter Zeit treten, als Spektraldichten regulärer Prozesse, $n \times n$ Matrizen $f(\lambda)$, $-\pi \leq \lambda \leq \pi$, in L_1 auf, die Faktorisierungen der Form $A(e^{-i\lambda})A^*(e^{-i\lambda}) = 2\pi f(\lambda)$ zulassen, wobei A eine im Einheitskreis holomorphe $n \times q$ Matrix der Klasse H_2 bildet. Existiert eine solche Faktorisierung, so hat f fast überall ein und denselben Rang m, und Kreĭn zeigte, daß es dann unter den $n \times m$ Faktorisierungen eine maximale A_0 im folgenden Sinne gibt: (*) $A(z)A^*(z) \leq A_0(z)A_0^*(z)$, $|z| \leq 1$, bei jeder $n \times m$ Faktorisierung A [Ju. A. Rozanov, Teor. Verojatnost. i Primenen. 5 (1960), 399–414; MR **24** #A2432]. Der Verfasser betrachtet nun allgemeiner $n \times q$ Matrizen A der Klasse H_2, wobei nicht notwendig $q = m$, für die $A(e^{-i\lambda})A^*(e^{-i\lambda}) \leq 2\pi f(\lambda)$ gilt, und beweist folgendes: Es ist $A(z) = A_0(z)E(z)$, wobei $E(z)$ holomorph in $|z| \leq 1$ mit $E(z)E^*(z) \leq I_m$ ist; die Ungleichung (*) gilt wiederum, und trifft darin das Gleichheitszeichen in einem Punkt z_0 zu, so trifft es überall zu und man kann E als konstante Matrix so wählen, daß $EE^* = I_m$ wird.

Borovkov, A. A.; Rogozin, B. A. 6551

Boundary-value problems for some two-dimensional random walks. (Russian. English summary)

Teor. Verojatnost. i Primenen. **9** (1964), 401–430.

The first author has been engaged in the study of asymptotic expansions concerning boundary problems for the sums of independent random variables [Borovkov, Sibirsk. Mat. Ž. **3** (1962), 645–694; MR **26** #3099]. Consider now two independent systems of identically distributed independent variables, $\xi_1^{(i)}, \xi_2^{(i)}, \cdots, i = 1, 2$, with $\xi_k^{(2)} \geq 0$, their respective sums $S_k^{(i)}$, $k = 1, 2, \cdots, S_0^{(i)} = 0$, and put $\bar{S}_n = \max_{1 \leq k \leq n} S_k^{(1)}$, $\eta_t = \sup\{k : S_k^{(2)} < t\}$. Assuming that the $\xi_k^{(1)}$'s are lattice variables the authors obtain asymptotic expansions for the joint distribution of $\bar{S}_{\eta_t}, S^{(1)}_{\eta_t+1}, S^{(2)}_{\eta_t+1}$, e.g., an asymptotic expansion of $\mathbf{P}(\bar{S}_{\eta_t} < x, S^{(1)}_{\eta_t+1} = x + y, S^{(2)}_{\eta_t+1} = t + s)$ when $t \to \infty$, $x/t \to 0$. Those expansions are effective to wide ranges of deviations including the limit theorems of Cramér's type. The analytical tools are similar to those in the paper cited above. The results obtained are also applied to get asymptotic expansions for the Kolmogorov-Smirnov test.

Bretagnolle, Jean; Dacunha-Castelle, Didier 6552

Marches aléatoires récurrentes sur R^p.

C. R. Acad. Sci. Paris **259** (1964), 2765–2768.

The authors study recurrent random walk (sums of identically distributed independent random walk) on R^p (Euclidean space of dimension p). The transition probability measure μ is assumed to have an absolutely continuous component, and when $p = 1$ additional conditions are imposed (in order to ensure the success of the Fourier analytical methods employed). Under these conditions the random walk has a potential kernel $U_x = \sum_{n=1}^{\infty} [\mu_x^n - \mu^n]$ (where μ^n is the nth convolution of μ, and μ_x^n the translate of μ^n by x). Just as in the reviewer's work on Z^p, it is shown that $U_{x+y} - U_x$ tends to 0 as $|x| \to \infty$ when $p = 2$, while the limit is $\pm y\sigma^{-2}\lambda$ as $x \to \pm\infty$ when $p = 1$. Here $\sigma^2 \leq \infty$ is the variance of μ, and λ is Lebesgue measure.

Ein Wahrscheinlichkeitsmodell für die symmetrische, lineare Irrfahrt mehrerer Teilchen.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), pp. 405–416. *Publ. House Czech. Acad. Sci., Prague*, 1964.

The author calculates the invariant distribution of a finite Markov chain (irreducible and aperiodic) with continuous time parameter which describes a certain physical model. In this model, when the physical system is of size n, the number of possible states is 2^n and the infinitesimal generator $q_n(i,j)$ is given explicitly. Thus the invariant distribution $P_n(i)$ is the unique non-negative solution of the system of equations

$$\sum_{i=1}^{2^n} P_n(i)q_n(i,j) = 0, \qquad j = 1, 2, \cdots, 2^n,$$

with the normalized condition $\sum_{i=1}^{2^n} P_n(i) = 1$. The author obtains the recurrence formula for $P_n(i)$ and, using it, evaluates expectations of related physical quantities.

Neuts, Marcel F. 6554

Coordinate-wise symmetric random walks in n-space.

Simon Stevin **36** (1962/63), 131–139.

Consider a spatially homogeneous random walk on an n-dimensional Euclidean lattice space, such that one-step transitions occur only to neighboring states. The walk is assumed symmetric in the sense that the probability of a step to the right parallel to any given coordinate axis equals the probability of a step to the left. The author derives a representation for $P_{xy}^{(k)}$ (the k-step transition probability from a lattice point x to a lattice point y), which is similar to the standard inversion formula for the characteristic function of $P_{xy}^{(k)}$. This representation is used to give another proof of the fact that the walk is recurrent in dimensions 1 and 2 [Chung and Fuchs, Mem. Amer. Math. Soc. No. 6 (1951); MR **12**, 722].

Reimann, J. 6556

Unsymmetrical random walk on the plane and in the space with absorbing barriers.

Acta Math. Acad. Sci. Hungar. **15** (1964), 339–354.

Let R be a rectangle of lattice points on the plane and let each lattice point on the boundary be an absorption point. In this paper the author considers an (absorbing barrier) random walk on R, more general than the usual one, for which the points that can be reached in one step from an interior point (i,j) are the starting point itself and 8 neighboring points, $(i\pm1, j)$, $(i, j\pm1)$, and $(i\pm1, j\pm1)$, with certain restrictions on the one-step transition probabilities in diagonal directions. According to the author's opinion, "this increase of the number of neighboring points is important, e.g., from the point of view of the solution of the Poisson differential equation with the lattice method, where it greatly increases the goodness of the approximation for a given lattice density". Using a matrix method, he computes the n-step transition probabilities of such a random walk with application to absorption problems. The three-dimensional case is also discussed.

T. Watanabe (Princeton, N.J.)

Shepp, L. A. 6557

Recurrent random walks with arbitrarily large steps.

Bull. Amer. Math. Soc. **70** (1964), 540–542.

A random walk $S_n = X_1 + \cdots + X_n$ (the X_i are identically distributed independent random variables with distribution function F) is recurrent if $P[|S_n| < 1$ for infinitely many $n = 1, 2, \cdots] = 1$. It is shown that the distribution F of a recurrent random walk (rec.r.w.) may have arbitrary large tails, viz., given $\varepsilon(x)$, $x \geq 0$, with $\varepsilon(x) \to 0$ as $x \to \infty$, there exists a rec.r.w. with d.f. F, such that for some x_0, $1 - F(x) = F(-x) \geq \varepsilon(x)$, $x \geq x_0$. Under additional assumptions on $F(x)$ (such as convexity for x sufficiently large) such a transient random walk cannot exist [the author, Trans. Amer. Math. Soc. **104** (1962), 144–153; MR **25** #2648].

Sherman, S. 6558

Fluctuation and periodicity.

J. Math. Anal. Appl. **9** (1964), 468–476.

Some connections are deduced between the distribution of certain functionals of random walk on the integers and an identity due to Witt concerning the dimension of certain subspaces of a free Lie algebra. Specifically, the Witt identity in the context of free semigroups deals with "words" and their permutations, and this suggested analogous identities concerning permutations of random walk paths. The characteristic function of the least concave polygon majorizing a random walk path of length n (defined somewhat differently than in the work of Sparre Andersen) is shown to satisfy an identity formally identical to that of the maximum M_n of a path of length n. Similar methods, also based on the Witt identity, lead to a new proof of known facts concerning M_n.

Tanaka, Hiroshi 6559

Note on continuous additive functionals of the 1-dimensional Brownian path.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **1** (1962/63), 251–257.

Let $a(t)$, $t \geq 0$, be a continuous additive functional of Brownian motion in R^1. The author proves that if I is any bounded interval in R^1 and T is the first time the Brownian motion leaves I, then for each $t \geq 0$, $a(\min(t, T))$ has finite moments of all orders. This result gives the author enough finiteness to obtain the representation $a(t) = f(x(t)) - f(x(0)) + \int_0^t g(x(s))\,dx(s)$ ($x(s)$ is the Brownian motion in question) for any such functional. (In this representation f is continuous, g satisfies some finiteness restrictions, and the integral is a stochastic integral.) The author comments that this representation has been obtained by others using different methods. The most noteworthy reference is to A. D. Ventcel' [Dokl. Akad. Nauk SSSR **142** (1962), 1223–1226; MR **27** #4265].

Fieger, Werner 6560

Zwei Verallgemeinerungen der Palmschen Formeln.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 107–122. *Publ. House Czech. Acad. Sci., Prague*, 1964.

For a call process $x(t)$ Palm has shown that we have

$$p(x(a+t)-x(a) = 0) = 1-\lambda\int_0^t \varphi_0(\tau)\,d\tau,$$

$$p(x(a+t)-x(a) = k) = \lambda\int_0^t \varphi_{k-1}(\tau)\,d\tau-\lambda\int_0^t \varphi_k(\tau)\,d\tau$$

$(k=1, 2, \cdots)$ for $0\leqq a<+\infty$, $0\leqq t<+\infty$, where

$$\varphi_i(t) = \lim_{\tau\searrow 0} p(x(t+\tau)-x(\tau) = i\,|\,x(\tau)\geqq 1),$$
$$i = 0, 1, 2, \cdots,$$

if the process is (1) stationary and (2) ordinary. Condition (1) implies that $\lim_{t\searrow 0}[p(x(t)\geqq 1)/t] = \lambda<+\infty$. Define

$$v_k(t) = p(x(t) = k), \qquad \psi_k(t) = p(x(t)\geqq k) = \sum_{i=k}^{\infty} v_i(t).$$

Condition (2) implies that if there exists a $\delta>0$ for an arbitrary $t>0$ and $\varepsilon>0$ so that for $0\leqq t_1<t_2\leqq t_1+\delta<t$, then $\psi_2(t_1, t_2)\leqq\varepsilon\psi_1(t_1, t_2)$, where

$$\psi_k(t_1, t_2) = p(x(t_2)-x(t_1)\geqq k) = \sum_{i=k}^{\infty} v_i(t_1, t_2)$$

and

$$v_k(t_1, t_2) = p(x(t_2)-x(t_1) = k).$$

In the paper it is shown that the Palm formula is applicable also in case only one of the two conditions (1) or (2) is fulfilled. *S. Ekberg* (Stockholm)

Mott, J. L. 6561

The distribution of the time-to-emptiness of a discrete dam under steady demand.

J. Roy. Statist. Soc. Ser. B **25** (1963), 137–139.

This note gives a simple combinatorial proof of the discrete analogue of Kendall's result [same J. **19** (1957), 207–212; discussion, ibid. **19** (1957), 212–233; MR **19**, 1092] for the probability of first emptiness of a dam subject to random integral inputs and steady unit demand.

J. Gani (E. Lansing, Mich.)

Yeo, G. F.; Weesakul, B. 6562

Delays to road traffic at an intersection.

J. Appl. Probability **1** (1964), 297–310.

Authors' summary: "A model for road traffic delays at intersections is considered where vehicles arriving, possibly in bunches, in a Poisson process in a one-way minor road yield right of way to traffic, which forms alternate bunches and gaps, in a major road. The gap acceptance times are random variables, and depend on whether or not a minor road vehicle is immediately following another minor road vehicle into the intersection or not. The transforms of the stationary waiting time and queue size distributions and the mean stationary delay for minor road vehicles are obtained by substitution of determined service time distributions into results for a generalisation of the $M/G/1$ queueing system. Some numerical results are given to illustrate the increase in the mean delay for variable gap acceptance times for a Borel-Tanner distribution of major road traffic, and a partial solution is given for a two way major road."

This is the most general model for the major-minor road intersection considered so far although it is closely related to the work of Gaver [Operations Res. **11** (1963), 72–87]. Any further generalizations of this are likely to be quite cumbersome to solve exactly.

Bartholomew, D. J. 6563

An approximate solution of the integral equation of renewal theory.

J. Roy. Statist. Soc. Ser. B **25** (1963), 432–441.

Author's summary: "An approximation is given to the solution of the integral equation for the renewal density. The approximation is of particular value when the renewal distribution has a high degree of positive skewness. For an important class of such distributions it also provides an upper bound to the renewal density. Some numerical comparisons are given for renewal processes in discrete time. Other methods of obtaining an approximate solution to the equation are briefly reviewed and compared with the new method." *G. Weiss* (Bethesda, Md.)

Davis, A. W. 6564

On the characteristic functional for a replacement model.

J. Austral. Math. Soc. **4** (1964), 233–243.

Consider a system of n "ancestors" existing at time $t=0$, with ranked ages $0\leqq x_1<x_2<\cdots<x_n$. At successive instants (regeneration points) one individual in the system (the ith with probability p_i) is replaced by another of age zero. The author gives a scheme for computing the characteristic functional of $N(u, t)$, the number of individuals of age $\leqq u$ at time t. This is used in the evaluation of the characteristic function of $N(x, t)$ (fixed x), and the age distribution of the ith ranked individual at any time t. Limit distributions (as $t\to\infty$) are given.

★Probabilities and life.

Translated from the French by Maurice Baudin.

Dover Publications, Inc., New York, 1962. vi+87 *pp.* \$1.00.

This is a new translation of the fourth edition of *Les probabilités et la vie* [Presses Universitaires de France, Paris, 1943].

Kristiansson, Lars 6567

On the semi-Markov process and its block diagram representation with applications to aircraft mission analysis.

Saab Tech. Notes TN 55 (1964), 16 *pp.*

Author's summary: "The semi-Markov process is defined as a stochastic process in which the time is the independent variable and the dependent variable can assume only an enumerable number of discrete values ('states'), and where transition from one given state to another depends on the length of time spent in the given state. Provided that the process is described with the aid of frequency functions $d_j(t)$ which specify the probability of a certain state j being reached in the time interval $(t; t+\Delta t)$, simple process equations are obtained. These equations can readily be represented by means of block diagrams. There is perfect correspondence between the process and the electrical network with positive feedback. The utility of the process is illustrated by means of an example concerned with aircraft mission analysis."

★Introduction to statistical method.

McGraw-Hill Series in Probability and Statistics.

McGraw-Hill Book Co., New York-Toronto-London. 1964. x + 533 *pp.* $9.75.

This introductory text is designed for mature undergraduates in science and engineering programs. It gives a substantial background in statistical inference, with illustrative examples and exercises drawn from a variety of applications. *W. H. Fleming* (Providence, R.I.)

Fabian, Václav 6569

A new one-dimensional stochastic approximation method for finding a local minimum of a function.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 85–105. *Publ. House Czech. Acad. Sci., Prague,* 1964.

Let $R(x)$ be a real-valued function of a real variable and suppose for each x there is an observable random variable Y_x with $E[Y_x] = R(x)$. There has been a good deal of literature in the last ten years on the problem of finding sampling schemes which asymptotically locate the extrema of the function $R(x)$. In this paper the author discusses a method which in some cases converges to the set of local minima of the function $R(x)$. *J. R. Blum* (Albuquerque, N.M.)

Bhat, B. R. 6570

On the distribution of certain quadratic forms in normal variates.

J. Roy. Statist. Soc. Ser. B **24** (1962), 148–151.

The author considers a general vector normal variate $\mathbf{X}$, mean $\boldsymbol{\mu}$ and covariance matrix $\boldsymbol{\Sigma}$, and derives the following principal theorems. Theorem 2: Let $\mathbf{G}_0 = \mathbf{I}, \mathbf{G}_1, \cdots, \mathbf{G}_k$ be $k+1$ real, symmetric, linearly independent $n \times n$ matrices such that $\mathbf{G}_i\mathbf{G}_{i'} = c\mathbf{G}$ $(i, i' = 0, 1, 2, \cdots, k)$, where $\mathbf{G}$ is either the zero matrix or some $\mathbf{G}_i$ and c is some constant. Let $Q_i = \mathbf{X}'\mathbf{A}_i\mathbf{X}$ $(i = 1, 2, \cdots, l)$ be l quadratic forms, where $\mathbf{A}_i$ are linear functions of $\mathbf{G}_j$ $(j = 0, 1, \cdots, k)$, distributed independently as $c_i\chi^2(n_i)$ such that $\sum n_i = n$. Then $\boldsymbol{\Sigma}$ is also a linear function of $\mathbf{G}_j$. If $k+1 = l$ and $\mathbf{A}_i$ are linearly independent, $\boldsymbol{\Sigma}$ is a linear function of $\mathbf{A}_i$. (Here $\chi^2(n)$ denotes a non-central χ^2 variate with n degrees of freedom.) Theorem 3: If Q_1 and Q_2 are two real symmetric non-negative or non-positive quadratic forms, then a quadratic form or a linear form is distributed independently of $Q_1 + Q_2$ if and only if it is distributed independently of Q_1 and of Q_2. *P. Whittle* (Manchester)

Park, John H., Jr. 6571

Variations of the non-central t and beta distributions.

Ann. Math. Statist. **35** (1964), 1583–1593.

Let X be a normal variate with mean ξ and variance 1, and let Y be an independent non-central chi variate. Consider the variates $U_1 = X/Y$ and $U_2 = X/(X^2+Y^2)^{1/2}$. Their distributions are doubly non-central t and beta distributions, respectively, whose densities can be expressed as difficult integrals [or as double series]. The author derives simple asymptotic expressions for the densities, their modes, means, and variances. When Y has 1 degree of freedom, the densities of U_1 and U_2 can be represented fairly simply in terms of the error function. *S. W. Nash* (Vancouver, B.C.)

Siromoney, Gift 6572

Entropy of logarithmic series distributions.

Sankhyā Ser. A **24** (1962), 419–420.

Author's summary: "The logarithmic series distribution was introduced by Fisher and Williams. We show that there are two types of logarithmic series distributions, which we shall call Type I and Type II. We evaluate the entropies of the two distributions and present the corresponding interpretations."

Saunders, Sam C. 6573

On the use of a distribution-free property in determining a transformation of one variate such that it will exceed another with a given probability.

Sankhyā Ser. A **24** (1962), 239–250.

Author's summary: "Let X and Y be independent random variables, with continuous distributions $F \in \mathscr{F}$ and $G \in \mathscr{G}$, on the sample space $\mathscr{X}$. Let ω be a homeomorphism from $\mathscr{X}$ onto itself and define

$$H(\omega) = \int F(\omega)\, dG.$$

From samples of X and Y we form $\hat{F}$ and $\hat{G}$ which are estimates of F and G, respectively, and define an estimate of H, say $\hat{H}$,

$$\hat{H}(\omega) = \int \hat{F}(\omega)\, d\hat{G}$$

for $\omega \in \Omega$, a class of homeomorphisms linearly ordered by H. Interpreting $\omega(Y)$ as the strain under use ω and X as the strength (of some device), then $H(\omega) = P[X < \omega(Y)]$ represents the unreliability and $\hat{H}(\omega)$ is an estimate of it. If we use $\hat{H}$ to determine a use $\hat{\omega}$, then what is the probability that the true unreliability $\hat{H}(\omega)$ is too large? We examine this problem under the assumptions that $\hat{F}(F^{-1})$ and $\hat{G}(G^{-1})$ are distribution-free with respect to $\mathscr{F}$ and $\mathscr{G}$, respectively. This provides an answer in some cases and allows one to obtain stochastic bounds in others."

Doss, S. A. D. C. 6574

On uniqueness and maxima of the roots of likelihood equations under truncated and censored sampling from normal populations.

Sankhyā Ser. A **24** (1962), 355–362.

Author's summary: "It is shown that when estimating from truncated and censored samples both the parameters of normal populations jointly or only one of them, the other being known, the maximum likelihood estimating equations possess a unique solution and that solution provides the absolute maximum of the likelihood function for all samples of any size."

Atiqullah, M. 6575

On the randomization distribution and power of the variance ratio test.

J. Roy. Statist. Soc. Ser. B **25** (1963), 334–347.

Author's summary: "A particular matrix representation is given for the usual sum of squares of treatments in some commonly used designs. This representation simplifies appreciably the calculation of randomization moments under null and non-null hypotheses. Fisher's Z-transformation is applied to study the randomization distribution of the F-criterion. The behavior of power curves under randomization and normal theory conditions is studied." *J. Kiefer* (Ithaca, N.Y.)

Birch, M. W. 6576a

A new proof of the Pearson-Fisher theorem.

Ann. Math. Statist. **35** (1964), 817–824.

Birch, M. W. 6576b

Acknowledgment of priority.

Ann. Math. Statist. **36** (1965), 344.

From the author's summary: "This paper is concerned with the theorem that the χ^2 goodness of fit statistic for a multinomial distribution with r cells and with s parameters fitted by the method of maximum likelihood is distributed as χ^2 with $r-s-1$ degrees of freedom. . . . In this paper the theorem is proved under more general conditions than the combined conditions of Rao and Cramér [Rao, Sankhyā **20** (1958), 211–218; MR **21** #6059; and Cramér, *Mathematical methods of statistics*, Princeton Univ. Press, Princeton, N.J., 1946; MR 8, 39]." {The author considers his approach to contain two points of novelty. First, appropriate differentiability is assumed only at the "true" parameter value. (The second paper acknowledges Rao's prior use [Sankhyā Ser. A **23** (1961), 25–40; MR **25** #718] of a sufficient statistic for this.) The reviewer wonders how this weaker assumption is ever to be used, in view of the fact that this "true" value can be any point of the parameter space. Secondly, the author uses what he calls a "slightly unconventional" definition of maximum likelihood to include the case where the supremum of the likelihood is not attained, a definition which has in fact been used by several previous authors. The paper contains a large number of unclear passages; for example, in the statement of the theorem reference is made to the multinomial probability vector $\pi(\theta)$ at points θ of the compactification of the parameter space where π has not been defined.} *J. Kiefer* (Ithaca, N.Y.)

Fraser, D. A. S. 6577

On local unbiased estimation.

J. Roy. Statist. Soc. Ser. B **26** (1964), 46–51.

The concept "local unbiasedness" is introduced and investigated: A statistic $h(x_1, \cdots, x_n)$ is locally unbiased for θ at θ_0 if

$$Eh((x_1, \cdots, x_n)\,|\,\theta_0\} = \theta_0 \text{ and } dE\{h(x_1, \cdots, x_n)\,|\,\theta\}/d\theta_0 = 1.$$

The statistic $S(\mathbf{x}) = \sum_{i=1}^n \partial \log f(x_i\,|\,\theta)/\partial\theta_0$ is termed locally sufficient, and it is shown that $\theta_0 + S(\mathbf{x})/nI(\theta_0)$ (a misprint omits the n in the denominator), where $I(\theta)$ is Fisher's information, is the minimum-variance locally unbiased estimate at θ_0. The discussion is extended to vector-valued parameters. It is shown that the locally unbiased estimates with minimum variance "piece together" to form a single overall estimate only if the population distributions form an exponential family. An estimation programme is suggested in which the parameter space is split into small neighbourhoods.

H. D. Brunk (Columbia, Mo.)

Fraser, D. A. S. 6578

Local conditional sufficiency.

J. Roy. Statist. Soc. Ser. B **26** (1964), 52–62.

Consider a family of distributions $F(x\,|\,\theta)$ stochastically increasing in the neighbourhood of a parameter value θ_0. A linearizing transformation is introduced, yielding a random variable $\ell(x)$ which is locally translation-invariant. The vector of differences in observed values of ℓ is treated as an ancillary statistic. Local sufficiency, conditioned on this ancillary statistic, is introduced and studied. The large sample distribution of the local conditionally sufficient statistic is found to be normal. The conditional large sample variance is discussed.

H. D. Brunk (Columbia, Mo.)

Giri, N.; Kiefer, J. 6579

Minimax character of the R^2-test in the simplest case.

Ann. Math. Statist. **35** (1964), 1475–1490.

Authors' summary: "In the first nontrivial case, dimension $p=3$ and sample size $N=3$ or 4 (depending on whether or not the mean is known), it is proved that the classical level α normal test of independence of the first component from the others, based on the squared sample multiple correlation coefficient R^2, maximizes, among all level α tests, the minimum power on each of the usual contours where the R^2-test has constant power. A corollary is that the R^2-test is most stringent of level α in this case." *E. L. Lehmann* (Berkeley, Calif.)

Miller, Rupert G., Jr. 6580

A trustworthy jackknife.

Ann. Math. Statist. **35** (1964), 1594–1605.

A method for the reduction of bias in a parametric situation was introduced by Quenouille [J. Roy. Statist. Soc. Ser. B **11** (1949), 68–84; MR **11**, 262] and referred to by Tukey as a "jacknife". The author examines this method in a variety of situations, pointing out where it is effective and where it is of little use.

M. Rosenblatt (La Jolla, Calif.)

Shenton, L. R.; Bowman, K. 6581

Higher moments of a maximum-likelihood estimate.

J. Roy. Statist. Soc. Ser. B **25** (1963), 305–317.

Authors' summary: "For a distribution depending on a single parameter the first four sampling moments of the maximum-likelihood estimate to orders N^{-2}, N^{-3}, N^{-3} and N^{-4}, respectively, are given. Expressions for the measures of skewness γ_1 and γ_2 are also given. Several illustrative examples are included as a check on the heavy algebra. The paper extends earlier work by Haldane and Smith." *H. D. Brunk* (Columbia, Mo.)

Tallis, G. M. 6582

Further models for estimating correlation in discrete data.

J. Roy. Statist. Soc. Ser. B **26** (1964), 82–85.

Author's summary: "This note considers the distribution of the sum of n identically distributed multinomial variates X_i, the correlation coefficient for X_i and X_j being ρ for all i, j, $i \neq j$. The initial model, with n and $\mathbf{p}' = (p_1, p_2, \cdots, p_k)$ fixed, is generalized by allowing first n, then $\mathbf{p}$ and finally both n and $\mathbf{p}$ to be random variables." *H. E. Reinhardt* (Missoula, Mont.)

Halperin, Max 6583

Confidence interval estimation in non-linear regression.

J. Roy. Statist. Soc. Ser. B **25** (1963), 330–333.

The results of this paper are related to those of Williams [same J. **24** (1962), 125–139; MR **25** #1597], which are clearly applicable to a regression function with only one parameter entering non-linearly. In this paper it is shown that the procedure of Williams is applicable to a quite large class of functions in which more than one parameter enters non-linearly. The discussion implies that the regions or intervals obtained are confidence regions and intervals. *P. S. Dwyer* (Ann Arbor, Mich.)

Kabe, D. G. 6584

Multivariate linear hypothesis with linear restrictions.

J. Roy. Statist. Soc. Ser. B **25** (1963), 348–351.

This paper features a normal multivariate linear regression model and gives a criterion for the simultaneous testing of a set of linear estimable parametric functions. The introductory section states the problem and cites recent articles which the paper generalizes. The evaluation of three general integrals, useful in the derivation of the sections following, is presented in the second section. The third and fourth sections establish the criterion, its hth moment, and allied results. *P. S. Dwyer* (Ann Arbor, Mich.)

Wilk, M. B.; Gnanadesikan, R. 6585

Graphical methods for internal comparisons in multiresponse experiments.

Ann. Math. Statist. **35** (1964), 613–631.

The authors, who believe that "the objectives of statistical analysis are neither so narrow nor so formal as described and implied by some statistical theories of estimation and testing hypotheses", propose a procedure for graphical analysis of multivariate data which is an analogue and extension of the method of half-normal plotting due to Daniel [Technometrics **1** (1959), 311–341; MR **22** #A3009]. *S. G. Ghurye* (Bloomington, Ind.)

Mardia, K. V. 6586

Some results on the order statistics of the multivariate normal and Pareto type 1 populations.

Ann. Math. Statist. **35** (1964), 1815–1818.

The author finds the distribution of the vector of smallest order statistics in a random sample of size n from a k-variate Pareto type 1 population [see the author, same Ann. **33** (1962), 1008–1015; MR **27** #871]. He then derives the distributions of the vectors of ranges in random samples of sizes $n = 2, 3$ from k-variate Pareto type 1 and k-variate normal populations. *S. W. Nash* (Vancouver, B.C.)

★Contributions to order statistics. 6587

Edited by Ahmed E. Sarhan and Bernard G. Greenberg. *John Wiley & Sons, Inc., New York-London*, 1962. xxv + 482 *pp*. $11.25.

The editors state in a preface that "the first aim of this monograph has been to assemble scattered materials to help applied research workers learn to use the tools of order statistics. A secondary aim is to provide materials and references that will facilitate further research in methodology". It is indicated that the contributors were asked to prepare articles following an outline of planned contents. The emphasis is less in the direction of (for example) rank-order methods than in that of asymptotically efficient estimation of scale and location parameters using linear combinations of order statistics. The latter developments are introduced in Chapters 3–5 by E. H. Lloyd, J. Jung, G. Blom, and J. Ogawa, after an introduction by H. A. David and a chapter on distributions and moments by Ogawa.

The remainder of Part I (the "theoretical part") of the book consists of a chapter on extreme values by E. J. Gumbel; a section on short-cut tests in normal theory by H. A. David, and a short one on the closest two out of three observations by J. Lieblein; a chapter on nonparametric confidence intervals and tolerance regions by J. E. Walsh; and one on multiple decisions and multiple comparisons by H. A. David.

There is little new theoretical development in these chapters; for the most part, they survey known results in chosen areas. The level of rigor and ratio of statements to detailed proofs varies from chapter to chapter. It would have been more useful if one comprehensive article had replaced the closely related and somewhat overlapping efforts of the four authors of Chapters 3–5, especially since this work is much less well known than the rest of Part I.

Part II ("specific applications") is concerned mostly with the normal distribution (H. Ruben, D. Teichroew, Sarhan and Greenberg, Ogawa, W. J. Dixon), but there are also chapters on the exponential distribution (Sarhan and Greenberg, B. Epstein, Ogawa) and on "other distributions", including the rectangular, gamma, and extreme value (Sarhan and Greenberg, Lieblein, Gumbel, S. Gupta, Lloyd). Typically, moments of order statistics are given and computations are made which implement the theory of Part I, for example, in the determination of optimum coefficients for the estimators discussed in Chapters 3–5. A major value of the book is in the 75 tables and numerous charts, many gathered from previous publications. There is also an extensive bibliography.

The practical worker will certainly find this a useful handbook and reference work, although he will be

disappointed if he seeks either detailed proofs of all developments or, perhaps more important, many detailed practical examples of a less than routine nature.
J. Kiefer (Ithaca, N.Y.)

Rosengard, Alex 6588
Indépendance limite uniforme d'un quantile et des valeurs extrêmes d'un échantillon.
C. R. Acad. Sci. Paris **259** (1964), 2955–2956.
The author continues his study of "asymptotic uniform independence" of certain order statistics from a sample of independent observations [same C. R. **258** (1964), 5786–5788]. He shows that the extreme values and the sample quantile of order k, $0<k<1$, are asymptotically uniformly independent. The result is more general and the proof much simpler than that in an earlier, unpublished paper of the reviewer. *S. M. Berman* (New York)

Sugiura, Nariaki 6589
The bivariate orthogonal inverse expansion and the moments of order statistics.
Osaka J. Math. **1** (1964), 45–59.
Denote by $X_{r/n}$ the rth member in ascending order of magnitude in a random sample of size n from a distribution function with mean μ and finite variance. In a previous paper [same J. **14** (1962), 253–263; MR **26** #859] the author derived bounds for $\mathrm{E}(X_{r/n})$. For $1\leqq r<s\leqq n$, he now uses bivariate extensions of his earlier techniques to derive similar bounds for $\mathrm{E}(X_{r/n}X_{s/n})$; and for symmetric distributions with $\mu=0$, bounds are also derived for $\mathrm{E}(X_{r/n}^i X_{s/n}^j)$ when $i,j=1,2$. Some numerical comparisons are made with exact values available when $i=j=1$.
R. L. Plackett (Newcastle upon Tyne)

Takács, Lajos 6590
The use of a ballot theorem in order statistics.
J. Appl. Probability **1** (1964), 389–392.
The author's generalized ballot theorem [Ann. Math. Statist. **33** (1962), 1340–1348; MR **25** #4580; J. Appl. Probability **1** (1964), 69–76; MR **28** #5495] is applied to obtain the exact distribution of

$$\sup_{\alpha\leq F(u)\leq\beta}[F_n(u)-\gamma F(u)]G(u)\quad\text{for } 0\leqq\alpha<\beta\leqq 1\leqq\gamma,$$

in the two cases $G(u)\equiv 1$ and $G(u)=1/F(u)$, where F_n is the empirical d.f. of n independent random variables with common continuous d.f. F. For special values of α,β,γ the problem had been considered by many authors beginning with Smirnov, but this is the first general treatment.
J. Kiefer (Ithaca, N.Y.)

Takács, Lajos 6591
Fluctuations in the ratio of scores in counting a ballot.
J. Appl. Probability **1** (1964), 393–396.
Suppose that in a ballot candidate A scores a votes and candidate B scores b votes and that all the possible $\binom{a+b}{b}$ voting records are equally probable. Denote by α_r and β_r the number of votes registered for A and B, respectively, among the first r votes recorded. Let μ be a non-negative integer. Denote by $P_j(a,b)$ the probability that the inequality $\alpha_r>\mu\beta_r$ holds for exactly j subscripts $r=1,2,\cdots,a+b$. Special results have been obtained by many authors, going back to the 19th century. The author previously [Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **2** (1963), 118–121; MR **28** #3490] determined $P_j(a,b)$ for $a>\mu b$, and here obtains the complete result. This result is based on a combinatorial calculation of the distribution of the number of r $(1\leq r\leq M)$ for which $\nu_1+\cdots+\nu_r<r$, where the ν_i are interchangeable non-negative lattice random variables.
J. Kiefer (Ithaca, N.Y.)

Dayhoff, Eugene 6592
On the equivalence of polykays of the second degree and Σ's.
Ann. Math. Statist. **35** (1964), 1663–1672.
Hooke introduced bipolykays to apply to sampling from a two-way array [same Ann. **27** (1956), 55–79; MR **17**, 868]. Wilk and Kempthorne introduced a set of functions, denoted by Σ's, in connection with certain structural patterns in the analysis of variance [J. Amer. Statist. Assoc. **52** (1957), 218–236; MR **19**, 474]. These were extended to include all balanced population structures by Zyskind [Sankhyā Ser. A **24** (1962), 115–148; MR **26** #1973], who conjectured the equivalence of extended polykays with the set of Σ's for all balanced structures. In this paper the theory of "n-way polykays" is developed so as to apply to all balanced structures, and the equivalence of these with the Σ's is established. *P. S. Dwyer* (Ann Arbor, Mich.)

Atkinson, F. V.; Church, J. D.; Harris, B. 6593
Decision procedures for finite decision problems under complete ignorance.
Ann. Math. Statist. **35** (1964), 1644–1655.
The authors contribute to the axiomatization of decision-making under complete ignorance as to the state of nature, a continuation of the earlier work of Chernoff [Econometrica **22** (1954), 422–443; MR **16**, 271] and Milnor [*Decision processes*, pp. 49–59, Wiley, New York, 1954; MR **16**, 605]. Let the element a_{ij} of the matrix A be the loss under decision i if state j prevails. Since the individual can mix strategies, he can achieve any loss vector in $C(A)$, the convex hull of the rows of A. Let $Q(A)$ be the set of chosen loss vectors in $C(A)$. The authors present a set of desirable properties for $Q(A)$. $Q(A)$ must be non-null and convex, and each element must be admissible. If $A_1=\lambda A_0+C$, where each row of C is the same vector, c, then $Q(A_1)$ is the image of $Q(A_0)$ under the linear transformation, $\lambda x+c$. The concept of complete ignorance (all a priori distributions over states of nature have equal status) is rendered by the following assumption (combining two of the authors'). If A_1 and A_2 are two matrices, and if the convex hull of the columns of A_1 is the same as that of A_2, then the chosen strategies (rows) of the two matrices are the same. It is also assumed that $Q(A_1)=Q(A_2)$ if the admissible extreme points of $C(A_1)$ and $C(A_2)$ are the same, and, finally, that the point-to-set mapping $Q(A)$ is upper semi-continuous (the last property does not hold, for example, for the minimax of regret criterion). It is not assumed that the choice of decisions is transitive. The main result is the exhibition of a class of decision procedures satisfying these criteria, modifying an earlier result of Milnor's. Let $\{\varepsilon_i\}$ be a positive sequence approaching zero. For given A, define inductively the sequence of sets

$\{Q_k\}$, as follows. Let $Q_1 = O(A)$, $d(x, y) = \max_i |x_i - y_i|$, $v_i^{(k)} = \min_{x \in Q_k} x_i$, $v^{(k)}$ the vector with components $v_i^{(k)}$, $z_k = \min_{x \in Q_k} d(v^{(k)}, x)$, and $Q_{k+1} = \{x \in Q_k : d(v^{(k)}, x) \leq z_k + e_k z_1\}$. The sets Q_k have an intersection $Q(A)$, which is the desired procedure, satisfying all the conditions and, in fact, consisting of a single point. *K. J. Arrow* (Stanford, Calif.)

Hannan, E. J. 6594

Systematic sampling.

Biometrika **49** (1962), 281–283.

The author considers the estimate of the population mean of a stationary process obtained from observations distributed over an interval. He compares the variances of estimates based upon regularly spaced and randomly distributed observations, and derives recommendations for a preferable procedure in terms of the spectral density function of the process. The generalisation of the calculation to several dimensions is indicated.

Hanumantha Rao, T. V. 6595

An existence theorem in sampling theory.

Sankhyā Ser. A **24** (1962), 327–330.

Author's summary: "A (1, 1) correspondence is established here, between sampling designs and sampling schemes, for sampling from a finite population. This result enables us to search for optimum sampling procedures in any particular case, through a unified general set-up."

Hanurav, T. V. 6596

Some sampling schemes in probability sampling.

Sankhyā Ser. A **24** (1962), 421–428.

Author's summary: "In this paper we give a sampling scheme for finite populations, resulting in a given set of inclusion probabilities. Also, we give another scheme with the property that it can be stopped at any stage without distorting the proportionate values of the inclusion probabilities."

Matérn, Bertil 6597

★Spatial variation: Stochastic models and their application to some problems in forest surveys and other sampling investigations.

Meddelanden Fran Statens Skogsforskningsinstitut, Band 49, *Nr.* 5, *Stockholm*, 1960. 144 *pp*. 8.00 *kr*.

The author is concerned with stationary stochastic processes $\{z(x)\}$ in several dimensions (very often on a plane in physical space) with the ultimate aim of discussing the design and accuracy of forest surveys.

In Chapter 2 special attention is paid to the correlation function $c(v)$ of an isotropic process, for which some interesting representations and inequalities are presented. The variance of the integral of $z(x)$ over a region is discussed.

The author considers a number of special models in Chapter 3; these are largely derived from a Poisson process by the association of a weight function or a geometrical region with each "event", but lead to an interestingly large class of correlation functions. For some processes which divide the space R_n into random sets, $c'(0)$ is found to be relatable to the expected set boundary-content per unit volume of R_n. A corollary of this result is that the expected length of the level curves of a Gaussian process is related to $\sqrt{-c''(0)}$.

The author now considers the estimation of a local mean of $z(x)$ (in R_2) by stratified sampling (i.e., by random sampling within a "stratum" which consists of a spatial region of prescribed geometric shape). He gives an asymptotic argument to show that the circle is the optimal stratum shape for all $c(v)$, and conjectures that the regular hexagon will be optimal if it is required that the strata should fill R_2. Numerical comparisons are given.

The same problem is also examined for the case of systematic sampling and an investigation made of the optimal configuration of sample points. Numerical studies seem to indicate the hexagonal lattice as having a uniform advantage. Edge effects are considered briefly. Consideration is also given to the total distance travelled in taking the sample, which will sometimes be a component of sampling cost. If it is the only component of cost, then the optimal scheme is to sample continuously along parallel straight lines.

The final chapter is devoted to a number of topics important for sample surveys in R_1 and R_2: estimation of sampling error, the use of a two-phase sample (e.g., the combination of visual observations and more exact measurements), and the optimal location of observations confined to curves in R_2 (when the circle appears to be the best closed curve, a straight line the best open one).

Murthy, M. N. 6598

Almost unbiased estimators based on interpenetrating sub-samples.

Sankhyā Ser. A **24** (1962), 303–314.

Author's summary: "In this paper a technique is given for estimating unbiasedly any non-linear function of estimable parameters. The technique consists in estimating the bias of the usual estimator using estimates based on interpenetrating sub-samples and then correcting the estimator for its bias."

Murthy, M. N. 6599

A note on determination of sample size.

Sankhyā Ser. A **25** (1963), 381–382.

Author's summary: "In this note a procedure of determining the sample size is proposed, where the idea is to fix the sample size in such a way that the probability (P) of the length (L) of the confidence interval (associated with a specified confidence coefficient) for the parameter (μ) being less than a given value ($k\mu$) is a pre-specified quantity."

Särndal, Carl-Erik 6600

★Information from censored samples.

Almqvist & Wiksell, Stockholm-Göteborg-Uppsala, 1962. 120 *pp*. *Sw. Kr.* 18.00.

From a purely theoretical point of view, the author studies the properties of linear unbiased estimates of α_1 and α_2, where $F[(z-\alpha_1)/\alpha_2]$ is a continuous distribution function with a location parameter α_1 and a scale parameter α_2, by censored sample from that population (having

$F[(x-\alpha_1)/\alpha_2]$ as the distribution function). He distinguishes between two different types of censoring. One is natural censoring that arises when, by the nature of the experiment, the individual values of observations with certain known ranks are not available; another is elective censoring where the observations which are to be deleted are by choice, whereas in natural censoring they are involuntarily lost. In the latter case, it is an important problem to determine the optimum spacing of observations. He defines evaluation of the loss (efficiency of the estimators). In Chapter I, he gives a review of well-known results in the theory of linear estimation, with fundamental definitions, conditions and prerequisites. Then in Chapter II he gives the measures of information and loss of information due to censoring and studies them in some cases of censoring in the unit interval when the size of the sample n is large. In Chapter III, he treats the case of small samples as a complement to the large-sample theory of the previous chapter. In Chapter IV, which is the most important part of this book, he studies the spacing of observations (elective censoring) in the case of no natural censoring in the original sample. Here he defines a function $f^*(x)$ by which the spacings are generated; he refers to it as the generating function. Thus, he derives some theorems on the efficiency of estimators by $f^*(x)$ and requires the generating function of optimum spacing which maximizes the efficiency. In Chapter V, he gives optimum and nearly optimum spacing, for small samples, corresponding to Chapter IV. In Chapter VI, he treats the problems on spacing of observations when part of the original sample is naturally censored (the information of the available sample has been already lost by natural censoring). In the last chapter, some applications to the problem of grouping of observations and that of stratification in sample survey are briefly described.

C. Hayashi (Tokyo)

Pathak, P. K. 6601

On simple random sampling with replacement.

Sankhyā Ser. A **24** (1962), 287–302.

Author's summary: "In simple random sampling with replacement, Basu [Sankhyā **20** (1958), 287–294; MR **21** #4517] and Des Raj and Khamis [Ann. Math. Statist. **29** (1958), 550–557; MR **20** #1377] showed that for estimating the population mean, the average of distinct units is more efficient than the overall sample mean. In this paper, a detailed treatment of the above problem is given, and the exact expression for the variance of above estimator is derived. The relative efficiency of the above estimator with other estimators is also considered. An improved estimator of the population variance is obtained. Finally, a comparison between the two simple random sampling schemes (with and without replacement) is made."

Pathak, P. K. 6602

On sampling with unequal probabilities.

Sankhyā Ser. A **24** (1962), 315–326.

Author's summary: "This paper deals with the problem of deriving improved estimators in sampling schemes with unequal probabilities of selection. The improved estimator of the population total Y [D. Basu, Sankhyā **20** (1958), 287–294; MR **21** #4517] is derived. In addition, two sets of estimators of Y and Y^2 are given. The first set of estimators is unwieldy to compute, while the second set is simple. The second set of estimators, though less efficient than the first, is more efficient than the usually employed estimators. It is proved in subfield terminology that if $\mathcal{S}_1$ and $\mathcal{S}_2$ are two sufficient subfields and K is a set common to $\mathcal{S}_1$ and $\mathcal{S}_2$, then $\mathcal{S}_1K+\mathcal{S}_2K'$ is also a sufficient subfield. Hence the subfield $\mathcal{S}_1K+\mathcal{S}_2K'$ can be used to derive improved estimators by Rao-Blackwell theorem. Generalisation of this is also given in case of a countable number of subfields. Application of this result to sampling with unequal probabilities is given."

Ruben, Harold 6603

Studentisation of two-stage sample means from normal populations with unknown variances. II. Confidence estimation for the mean of a stratified population.

Sankhyā Ser. A **24** (1962), 251–254.

Author's summary: The two-stage sampling procedure discussed in the first paper of the present series [Sankhyā Ser. A **24** (1962), 157–180; MR **27** #3045] is used to obtain confidence intervals of predetermined length and confidence coefficient for the mean of a stratified population with normal components. The efficiency of the procedure in relation to the confidence estimation with fixed sample sizes, when the variances of the component strata are known, is discussed briefly."

Ruben, Harold 6604

Studentisation of two-stage sample means from normal populations with unknown variances. III. Joint confidence estimation of a set of means.

Sankhyā Ser. A **24** (1962), 255–258.

Author's summary: "Confidence regions of predetermined dimensions and confidence coefficient are obtained for the joint estimation of the means of a finite set of unconnected and unknown normal populations. The confidence estimation procedure is shown to be conservative in character, and its efficiency in relation to the corresponding estimation procedure with fixed sample sizes, when the variances of the populations are known, is discussed briefly. The paper concludes with a short discussion of the possibility of increasing the efficiency of the two-stage sampling procedure (utilised in the current paper as well as in the preceding two papers of this series [Sankhyā Ser. A **24** (1962), 157–180; MR **27** #3045; see also #6603 above]), and of some other matters."

Tukey, John W.; McLaughlin, Donald H. 6605

Less vulnerable confidence and significance procedures for location based on a single sample: Trimming/Winsorization. I.

Sankhyā Ser. A **25** (1963), 331–352.

Authors' summary: "The vulnerability of Student's t, insofar as efficiency and power are concerned, leads to consideration of substitutes. Among the most promising are ratios of trimmed means to square roots of suitable quadratic forms involving the same order statistics. Matching, across underlying distributions, of ratios of average of denominator to variance of numerator leads to selection of the Winsorized sum of squared deviations as the basis for a denominator. The resulting trimmed t

should prove more useful when the amount of trimming is made to depend on the individual sample in a suitably prescribed manner. Exact critical values for the resulting tailored t seem to require Monte Carlo computation, but use of a simple modified denominator for trimmed t allows us to use the conventional t tables as a reasonable approximation."

Rao, J. N. K.; Tintner, G. 6606

The distribution of the ratio of the variances of variate differences in the circular case.

Sankhyā Ser. A **24** (1962), 385–394.

Authors' summary: "In time series analysis, the variate difference method is used to test the order of the finite difference at which the trend or the systematic part in the time series is approximately eliminated. There is no exact test available in the literature except for the one proposed by Tintner based on a method of selection which uses only a portion of the observations. In this paper, the statistic V_{k+1}/V_k is proposed to test that the trend is approximately eliminated at the kth finite differencing of the series, where V_k is the variance of the series of the kth differences. Its exact distribution assuming that the observations are $NI(0, \sigma^2)$ is derived under a circular definition of the universe. The lower 5% and 1% points of the statistics V_2/V_1 and V_3/V_2 are tabulated for various values of N, the size of the sample. In practice, one uses the non-circular statistic with these percentage points for the circular statistic as an approximation, especially with long time series."

★Iterative methods for the solution of equations.

Prentice-Hall Series in Automatic Computation.

Prentice-Hall, Inc., Englewood Cliffs, N.J., 1964. xviii + 310 *pp*. $12.50.

Consider the problem of approximating a real root of a real equation $f(x) = 0$. If $x_i, x_{i-1}, \cdots, x_{i-n}$ are $n+1$ approximants of α, and ϕ is a real function of $n+1$ variables, then $x_{i+1} = \phi(x_i, \cdots, x_{i-n})$ gives rise to an iteration algorithm; and particular interest centers, of course, around iteration functions (I.F.) ϕ for which the process converges to α. This is a very old problem and a great variety of such iteration algorithms have been discovered and rediscovered.

This book aims at a systematization of known I.F. and at classifying them according to the efficiency of the algorithm and the amount of computational labor involved. Although basic convergence theorems are included, the stress is almost exclusively on methods for constructing I.F. and on determining their principal properties. Except for Chapter 11, only the special case is considered where f is a real function of one real variable and α an isolated real root. Moreover, except for Chapter 7, α is even assumed to be a simple root in many discussions.

In Chapter 1 the general classification of I.F. is introduced. A basic distinction is made between old and new information by considering I.F. where at the points $x_i, \cdots, x_{i-k}$ new data are used while at $x_{i-k-1}, \cdots, x_{i-n}$ old information is reused. Special cases are named as follows: $n = k = 0$, one-point I.F.; $n > k$, $k = 0$, one-point I.F. with memory; $n = k > 0$, multipoint I.F., and the general case is called a multipoint I.F. with memory. The classification of I.F. is further based on the "informational efficiency", $\mathrm{Eff} = p/d$, of the algorithm. Here p is the order of convergence of the iteration and d the total number of new derivative evaluations of f per iteration ($f = f^{(0)}$).

Chapter 2 begins with the basic contraction mapping theorem and a discussion of linear and superlinear convergence. Then the so-called iteration calculus is introduced, consisting of a number of fundamental theorems on I.F. without memory, as for example, theorems comparing the order of different I.F., etc.

Chapter 3 treats difference relations, including particularly the asymptotic behavior of the solution of certain difference equations. Later, these results form the basis for the order analysis of one-point I.F.

Chapter 4 provides the fundamental material for much of the remainder of the book by introducing interpolatory I.F. These are I.F. generated by direct or inverse hyperosculatory interpolation. The major results of this chapter concern the convergence and order of these interpolatory I.F.

Chapter 5 discusses one-point I.F. Generally, an infinite sequence of I.F. is called basic if its pth member is of order p. A basic sequence of one-point I.F., E_s, is obtained by inverse interpolation. Other techniques for finding one-point I.F. include the use of direct interpolation and the application of rational approximations to E_r. An important result for all one-point I.F. states that always $\mathrm{Eff} \leq 1$. Accordingly, a one-point I.F. is called optimal if $\mathrm{Eff} = 1$.

Chapter 6 studies two classes of one-point I.F. with memory, namely, interpolatory I.F. and so-called derivative estimated I.F. These are I.F. obtained by estimating the $(s-1)$st derivative of an optimal one-point I.F. of order s with the aid of one new and n old values of the first $s-2$ derivatives. For these two types of I.F. it is shown that the old information adds always less than unity to the order.

Throughout Chapters 4–6 the root α was mostly assumed to be simple. Chapter 7 now generalizes the results to multiple roots. Every E_s turns out to be of linear order for non-simple roots, and a new basic sequence with multiplicity-independent order has to be introduced. Then further techniques for constructing one-point I.F. with memory for non-simple α are discussed.

Chapters 8 and 9 turn to multipoint I.F. These have various computational advantages; e.g., there is no limit for Eff, some of them have free parameters permitting sampling at desirable points, etc. Various techniques for generating multipoint I.F. are introduced. One is based on a special type of interpolation formula, others use recursively defined I.F., the composition of I.F., and the estimation of the highest derivative in a one-point I.F. Then two particular families of multipoint I.F. are investigated in detail.

Chapter 10 contains a brief discussion of various material on I.F. which involve no derivatives, and Chapter 11 presents an introduction to the case where f is replaced by a system of equations. Inverse interpolation

techniques are again employed and error estimates for some vector-valued I.F. are given.

Chapter 12 contains a very valuable compilation of all I.F. discussed in the book, listing in each case the formula, the order and asymptotic error constant, and the relevant section in the previous chapters.

The book concludes with 6 appendices and an extensive bibliography. Among the appendices, the first one brings a summary of results on hyperosculatory interpolation, and the fifth one provides a selection of the author's computer experimentation with various I.F.

Although the mathematical treatment is rigorous throughout, attention is definitely focused on the computational aspects of the topic. There is a vast amount of material in the book and a great deal is either new or presented in a new form. Many examples are provided to show how well-known I.F. are special cases of the general results. The style is terse and tends to make for somewhat uninspired reading, and yet the author has certainly succeeded in presenting a systematic account of a large class of known I.F., and this makes the work an interesting basic text as well as a valuable reference book for this field. *W. C. Rheinboldt* (Silver Spring, Md.)

Quadratwurzeln von 1–1000 nebst Reziproken auf 20 Dezimalstellen sowie deren summatorische Funktionen.
Wiss. Z. Ernst-Moritz-Arndt-Univ. Greifswald Math.-Natur. Reihe **12** (1963), *no.* 3/4, *Beilage,* 41 *pp.*

The first article is an introduction to the tables which are in the second. Apart from historical and bibliographical remarks, it includes an asymptotic expression for $\sum^n k^{-1/2}$ and describes situations in lattice energy studies where many-decimal tables of $k^{-1/2}$ are convenient.

The tables give $n^{\pm 1/2}$ for $n = 1(1)1000$ to 20D, with an indication as to whether the rounding was up or down. The sum functions $\sum_1^n k^{\pm 1/2}$ are also given; those final digits which may have suffered from the rounding in the primary tables are given in small type.
John Todd (Pasadena, Calif.)

Klopfenstein, R. W. 6611
Conditional least squares polynomial approximation.
Math. Comp. **18** (1964), 659–662.

The basic problem of polynomial least squares curve fitting on an automatic computer is effectively solved by the generation of orthogonal polynomials by recurrence, as described by Forsythe [J. Soc. Indust. Appl. Math. **5** (1957), 74–88; MR **19**, 1079]. In the present paper, the author shows, briefly and clearly, how constraints may be imposed upon the fitting polynomial. He seems to be unaware, however, of Forsythe's work, and of the more recent papers on the subject; in particular, there appears to be nothing in the paper that was not earlier given, in rather greater generality, by Cadwell and Williams [Comput. J. **4** (1961/62), 260–264; MR **23** #B2571].

A note on extension of the Lagrange inversion formula.
Comm. Pure Appl. Math. **17** (1964), 137–146.

The author extends the Lagrange-Burmann formula [for the one-dimensional case, see Whittaker and Watson, *A course of modern analysis*, fourth edition, Cambridge Univ. Press, Cambridge, England, 1927] to the case for a function of n variables. The method he develops for the reversion of series is done so that it can be adapted to large-scale digital computers. Although the analysis is quite nice, the details are such that they cannot be given here. *J. T. Day* (Zürich)

Brown, K. M.; Henrici, P. 6613
Sign wave analysis in matrix eigenvalue problems.
Math. Comp. **16** (1962), 291–300.

The paper deals with the power method in case of a dominant pair of simple, conjugate complex roots, $\lambda_1 = \rho e^{i\varphi}$, $\lambda_2 = \rho e^{-i\varphi}$, with a non-derogatory starting vector. Let $x_\nu^{(n)}$ denote the νth component of the nth iterated vector, and let $r_\nu e^{i\varphi_\nu}$ denote the νth component of some eigenvector to λ_1. If $r_\nu \neq 0$, then a classical result is that ρ^2 is approached by the quotient $\Delta_\nu^{(n+1)}/\Delta_\nu^{(n)}$ of successive 2×2 Hankel determinants $\Delta_\nu^{(n)} = (x_\nu^{(n)})^2 - x_\nu^{(n-1)}x_\nu^{(n+1)}$. This is supplemented by the following interesting result about the phase φ: the sequence of average distances of iterations between sign-changes from minus to plus in the sequence $x_\nu^{(n)}$ approaches $2\pi/\varphi$. Thus, the sign waves in the iteration sequence give additional information about the phase. This method is numerically stable even for very small absolute values of φ (whereas the determination of λ from a quadratic equation is unstable in this case); however, the smaller φ is, the more iterations will be necessary in order to produce a sign change. A similar result holds for the determination of the relative phase angles $\varphi_\nu - \varphi_1$ in an eigenvector. *F. L. Bauer* (Munich)

Brudno, A. L. 6614

ε-solutions of linear algebraic systems. (Russian)

Problemy Kibernet. No. 8 (1962), 187–190.

A rather labored examination of the question, under what conditions will an approximate solution x^* of the linear system $Ax+b=0$ satisfy $|Ax^*+b|\leq\varepsilon|Ax^*|$, where the inequality and the bars are to be interpreted elementwise. *A. S. Householder* (Oak Ridge, Tenn.)

Descloux, Jean 6615

Bounds for the spectral norm of functions of matrices.

Numer. Math. 5 (1963), 185–190.

Let $A=(a_{i,j})$ be any $n\times n$ complex matrix with eigenvalues $\mu_1, \mu_2, \cdots, \mu_n$, and denote the distinct eigenvalues of A by $\lambda_1, \lambda_2, \cdots, \lambda_m$ of respective multiplicities $n_1, \cdots, n_m$. Let $f(z)$ be any function for which the values $f^{(i)}(\lambda_j)$, $0\leq i\leq n_j-1$, $1\leq j\leq m$, exist. If

$$\sigma(A)\equiv\sup_{x\neq 0}\left[\left(\frac{x^*A^*Ax}{(x^*x)}\right)\right]^{1/2},\qquad \|A\|\equiv\left(\sum_{i,j}|a_{i,j}|^2\right)^{1/2},$$

$\Delta(A)\equiv(\|A\|^2-\sum_i|\mu_i|^2)^{1/2}$, and $g(z_1, z_2, \cdots, z_i)$ denotes the $(i-1)$st divided difference of a real- or complex-valued function $g(z)$ at the points $z_1, z_2, \cdots, z_i$, then the author proves that $\sigma(f(A))\leq\sum_{k=0}^{n-1}\delta_k(\Delta(A))^k$, where

$$\delta_{k-1}\equiv\max_{1\leq i_1<i_2<\cdots<i_k\leq n}|f(\mu_{i_1}, \mu_{i_2}, \cdots, \mu_{i_k})|$$

for $1\leq k\leq n$. This generalizes a result of Henrici [Numer. Math. 4 (1962), 24–40; MR 24 #B1751] for the function $f(z)=z^k$, and makes use of Henrici's notion of "departure from normality". *R. S. Varga* (Cleveland, Ohio)

Lavrov, S. S. 6616

Application of barycentric coordinates to the solution of certain numerical problems. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. 4 (1964), 905–911.

The author introduces barycentric coordinates to transform a function of degree m in n variables $F(x_0, x_1, \cdots, x_n)$ by $x_i=\sum\mu_k M_i^{(k)}$, $\sum\mu_k=1$, in a homogeneous form in μ_k. Taking the values of the function in the points $P(k_1/m, k_2/m, \cdots, k_n/m)$, one disposes of exactly as many values as there are coefficients in the form, and by a solution of a system of linear equations the transformation of the form is effected. Applications are given for the solution of a system of functions and for the determination of extreme values of a single function, by replacing given functions by linear or quadratic approximations in these barycentric coordinates. It might be of use to remark here that the author obtained fractions in his solutions because of the omission of a factor $m!$, which is used in the Clebsch-Weitzenböck symbolical method. The form is generally transformed from $(a'x)^m$ into

$$\sum\frac{m!}{i_0!i_1!\cdots i_n!}(a'M^0)^{i_0}\cdots(a'M^n)^{i_n}\mu_0^{i_0}\mu_1^{i_1}\cdots\mu_n^{i_n}$$

and the symbolical method gives for the values and the coefficients with m different indices the relation

$$(a_1'+a_2'+\cdots+a_l')^m=\sum\frac{m!}{s_1!s_2!\cdots s_n!}a'_{1\cdots 1 2\cdots 2 \cdots l\cdots l}.$$

From this fundamental relation the formulas for coefficients with equal indices are directly obtained. This corresponds to the choosing of the different points P by the author for $k_i\neq 1$ in a procedure which remains unchanged for arbitrary changes by linear transformation of the basic point set. *E. M. Bruins* (Amsterdam)

Lynn, M. Stuart 6617

Some infra-max bounds for the spectral radii of splittings of H-matrices.

Numer. Math. 5 (1963), 152–174.

Let $A=(a_{i,j})$ be an $n\times n$ matrix. A splitting $\{B, C\}$ of A is any pair of $n\times n$ matrices B and C such that $A=B-C$ and B is nonsingular. For the matrix equation $Ax=k$, a splitting $\{B, C\}$ of A then defines a natural iterative method for solving this equation: $Bx^{(n+1)}=Cx^{(n)}+k$. Previously, the reviewer [*Boundary problems in differential equations*, pp. 121–142, Univ. Wisconsin Press, Madison, Wis., 1960; MR 22 #12704] introduced the notion of a regular splitting $\{B, C\}$ of A, i.e., a splitting of A for which B^{-1} and C have only non-negative real entries ($B^{-1}\geq 0, C\geq 0$). Moreover, it was shown that if $A^{-1}\geq 0$, and $\{B, C\}$ is a regular splitting of A, then $\rho(B^{-1}C)<1$ and the iterative method defined above is necessarily convergent. Based on Ostrowski's well-known work [Comment. Math. Helv. 10 (1937), 69–96] on H-matrices and M-matrices, the author introduces here the related notion of an M-splitting $\{B, C\}$ of A, i.e., if $B=(b_{i,j})$ and $C=(c_{i,j})$, then $|a_{i,j}|=|b_{i,j}-c_{i,j}|=|b_{i,j}|+(-1)^{\delta_{i,j}}|c_{i,j}|$, $1\leq i, j\leq n$. For an H-matrix A, which in general does not possess regular splittings, the author shows that an M-splitting $\{B, C\}$ of A is convergent, $\rho(B^{-1}C)<1$, and obtains upper bounds less than unity for $\rho(B^{-1}C)$. On the other hand, it is shown that if A is an M-matrix and $\{B, C\}$ is an M-splitting of A, then $\{B, C\}$ is necessarily a regular splitting of A. Conversely, if A is an M-matrix and $\{B, C\}$ is a regular splitting of A with $b_{i,j}\leq 0$, $i\neq j$, then $\{B, C\}$ is also an M-splitting of A. Consequently, for most applications to elliptic difference equations, M-splittings and regular splittings are the same, and the author is able to rederive many known results in this area.

Working with partitioned matrices, the author then uses basic results of Ostrowski [J. Math. Anal. Appl. 2 (1961), 161–209; MR 24 #A421] to extend the previous results of M-splitting theory to partitioned matrices. Finally, defining restrictive splittings of a matrix A, applications are made to successive overrelaxation methods with relaxation factors ω slightly greater than unity. *R. S. Varga* (Cleveland, Ohio)

Niethammer, Wilhelm 6618

Relaxation bei komplexen Matrizen.

Math. Z. 86 (1964), 34–40.

First the author rediscovers independently a result recently published by Lynn [Comput. J. 7 (1964), 72–75], that if in the system $AX=C$ the matrix A has Property A, then symmetric successive overrelaxation with the factor $1+d$ is equivalent to successive overrelaxation with the factor $1-d^2$, and he extends this to show that unsymmetric overrelaxation with factors $1+d_1$ and $1+d_2$ is equivalent to successive overrelaxation with the factor $1-d_1d_2$. Thereafter he applies results found in a previous paper [Math. Z. 85 (1964), 319–327; MR 30 #705] to obtain optimal factors in the complex cases when $B=A-I$ is Hermitian, skew-Hermitian, and complex symmetric. *A. S. Householder* (Oak Ridge, Tenn.)

Price, Charles M. 6619

The matrix pseudo-inverse and minimal variance estimates.

SIAM Rev. **6** (1964), 115–120.

Author's summary: "This paper reviews and applies certain results concerning the matrix pseudo-inverse to the general theory of estimable functions and minimal variance estimates. The paper is divided into two sections. The first section reviews certain known results concerning the matrix pseudo-inverse. This section is essentially non-statistical. The second section uses results in the first section to state and prove a generalized version of the Gauss-Markoff theorem concerning unbiased linear estimates having minimal variance."

The first section is very useful in that it provides a handy reference. It succinctly lists the properties of the pseudo-inverse, the relations it satisfies, and the basic relevant theorems.

A new theorem is given which, for the non-zero eigenvalues, relates the eigensystems of a matrix A and its pseudo-inverse.

{The second footnote on page 116 has a misprint: for A^2, read A'.} *E. R. Hansen* (Palo Alto, Calif.)

Richards, Paul I. 6620

Symmetry in numerical matrix calculations.

SIAM Rev. **5** (1963), 234–248.

Cord and Sylvester [J. Soc. Indust. Appl. Math. **10** (1962), 632–637; MR **27** #3651] showed that if an ordinary differential equation defined on a finite open interval of the real line possesses mirror-type symmetry (i.e., the differential equation is unchanged when the independent variable is reflected about the midpoint of the interval), then a finite-difference approximation to this differential equation yields an $n\times n$ matrix $A=(a_{i,j})$ which has the property of cross-symmetry: $a_{i,j}=a_{n+1-i,n+1-j}$. If $n=2m$, then all the eigenvalues and eigenvectors of A can be obtained by finding the eigenvalues and eigenvectors to two lower-order matrices of order m. This implies a possible factor of four in reducing computing effort. The author, using the theory of group representations, generalizes these results by considering the group of all such symmetry transformations. An example of a 10×10 matrix is included, where saving factors from 4 to 40 are possible. *R. S. Varga* (Cleveland, Ohio)

Rutishauser, Heinz 6621

Une méthode pour le calcul des valeurs propres des matrices non symétriques.

C. R. Acad. Sci. Paris **259** (1964), 2758.

From a given matrix $A=A_0$, a sequence of equivalent matrices A_i is computed. Each step consists of a Jacobi rotation transformation of A_i with the axis (p,q) such that the (p,q)-element of the commutator $C_i=A_iA_i^H-A_i^HA_i$ is made zero, followed by a suitable diagonal transformation. A sweep consists of $\frac{1}{2}n(n-1)$ steps, where (p,q) are taken in the order $(1,2),(1,3),\cdots,(1,n),(2,3),\cdots,(2,n),(3,4),\cdots,(n-1,n)$. The algorithm is said to approximate a normal matrix in the sense that the norm of C_i approaches zero. *F. L. Bauer* (Munich)

Ostrowski's iteration method [Parts I–VI, cf. Arch. Rational Mech. Anal. **1** (1958), 233–241; ibid. **2** (1958/59), 423–428; MR **21** #427; ibid. **3** (1959), 325–340; MR **21** #4541a; ibid. **3** (1959), 341–347; MR **21** #4541b; ibid. **3** (1959), 472–481; MR **21** #6691; ibid. **4** (1959), 153–165; MR **22** #8654] which determines a sequence

$$l_k=y'_{k-1}Ay_{k-1}/y'_{k-1}y_{k-1}$$

tending to the eigenvalue m of a real symmetric matrix A, where the recurrent vector sequence

$$y_k=(A-l_kI)^{-1}y_{k-1}$$

approximates by its direction that of an eigenvector of A at m, is discussed from the point of view of programming for an electronic computer. *H. Schwerdtfeger* (Montreal, Que.)

Wachspress, Eugene L. 6623

Extended application of alternating direction implicit iteration model problem theory.

J. Soc. Indust. Appl. Math. **11** (1963), 994–1016.

The author extends his algorithm [same J. **10** (1962), 339–350; MR **27** #921] for determining optimum acceleration parameters for alternating direction implicit (ADI) iterative methods. In the commutative case ($HV=VH$), where H and V are real, symmetric and positive definite, consider the solution of the matrix problem $(H+V)\underline{z}=\underline{s}$ by means of the iterative method

$$(H+\omega_{k,H}I)\underline{z}^{(k+1/2)}=(\omega_{k,H}I-V)\underline{z}^{(k)}+\underline{s},$$

$$(V+\omega_{k,V}I)\underline{z}^{(k+1)}=(\omega_{k,V}I-H)\underline{z}^{(k+1/2)}+\underline{s}.$$

If the smallest intervals containing the eigenvalues of H and V are, respectively, $[a,b]$ and $[c,d]$, an algorithm is given for the 2^{m+1} optimum parameters $\omega_{k,H}$, $\omega_{k,V}$, $1\leq k\leq 2^m$, which minimize

$$\max_{\substack{\lambda\in[a,b]\\ \gamma\in[c,d]}}\prod_{k=1}^{2^m}\left|\frac{\lambda-\omega_{k,V}}{\lambda+\omega_{k,H}}\right|\cdot\left|\frac{\gamma-\omega_{k,H}}{\gamma+\omega_{k,V}}\right|.$$

In other words, the algorithm previously given for the "square" model problem is generalized to the "rectangular" model problem. Next, the combination of ADI iterations with Lanczos' method is applied to matrix problems for which $HV\neq VH$, but for which there exists a matrix $M=M_1+M_2$, where $M_1M_2=M_2M_1$, and M_1 and M_2 are real, symmetric, and positive definite. Unfortunately, such problems have application only to elliptic difference equations defined on rectangular domains. Numerical results of such combined iterations are included.

In this paper is found a most interesting appendix which describes W. B. Jordan's complete solution of the problem of determining m optimum acceleration parameters for the model problem for general m, using the theory of elliptic functions. In the special case $m=2^k$, the algorithm proposed by the author for determining the optimum parameters is probably the most efficient numerically. *R. S. Varga* (Cleveland, Ohio)

Robinson, Raphael M. 6624

Algebraic equations with span less than 4.

Math. Comp. **18** (1964), 547–559.

By the span of an algebraic equation all of whose roots are real is meant the difference between its largest and smallest roots. The author considers irreducible equations with integer coefficients and leading coefficient equal to 1, such that the roots form a set of conjugate algebraic integers with span less than 4. There are only finitely many such equations of span less than $4-\varepsilon$. Two such equations are considered equivalent if they are of the same degree and if the roots of one are obtainable from the roots of the other by adding a fixed integer or by changing signs. The representative of such an equivalence class is the one whose average root lies between 0 and $\frac{1}{2}$. The author has searched for all representative polynomials of degree n, completely for $2 \leq n \leq 6$ and nearly completely for $n = 7, 8$, and has found just 96 such polynomials, 19 being the familiar Chebyshev polynomials whose roots are the doubled cosines of rational multiples of 2π. The 77 other equations are distributed as to degree as follows.

Degree	2	3	4	5	6	7	8
No. of equations	1	3	10	14	13	15	21

Table 1 gives for each of the 96 equations the maximum and minimum distances between roots and the largest and smallest roots to 4D, their coefficients and their discriminant and its factorization. The 19 Chebyshev cases are conspicuous for the roundness of their discriminants. The other 77 discriminants are often primes. Table 2 gives all 96 sets of roots to 10D.

Stroud, A. H. 6628

Approximate integration formulas of degree 3 for simplexes.

Math. Comp. **18** (1964), 590–597.

Formulas for numerical integration with equal weights and order three are developed for the n-simplex. These formulas involve evaluation at $n(n+1)$ points. For $n \leq 8$ all points of evaluation may be taken in the simplex; for $n \geq 9$ it seems that all points must be exterior to the simplex. The formulas are shown to be related to certain orthogonal polynomials. An example is presented for $n = 3$ comparing with previously derived formulas of the author and of the author in collaboration with P. C. Hammer and O. J. Marlowe [the author, Math. Comp. **15** (1961), 143–150; MR **22** #12717; the author, the reviewer, and O. J. Marlowe, Math. Tables Aids Comput. **10** (1956), 130–137; MR **19**, 177].

On the computational solution of two-point boundary-value problems.

Boll. Un. Mat. Ital. (3) **19** (1964), 121–123.

One method of solving systems of linear two-point boundary-value problems of the form

$$(*) \qquad x'' + A(t)x = 0; \qquad x(0) = c,\ x(1) = d,$$

replaces (*) by an initial-value problem, i.e., the boundary condition at $t = 1$ is replaced by the initial condition $X'(0) = g$, where $g = X_2(1)^{-1}[d - X_1(1)c]$ and X_1 and X_2 are matrix solutions of the differential equation satisfying $X_1(0) = I$, $X_1'(0)$, $X_2(0) = 0$, and $X_2'(0) = I$. It is assumed that $X_2(1)$ is nonsingular. Since $X_2(1)^{-1}$ may be difficult to compute accurately, the authors describe an iterative procedure for the construction of a sequence of vectors $\langle g_n \rangle_{n=1}^{\infty}$ which, under certain conditions, converges to g.

Étude du comportement d'un système à retour non linéaire au voisinage d'un cas critique de Lyapunov.

C. R. Acad. Sci. Paris **258** (1964), 6069–6072.

To find the solutions of a polynomial equation

$$(1)\qquad \sum_{i=2}^{n} a_i y^i = z,$$

the authors have been experimenting with a differential system (2) $y''' + by'' + cy' + dy + \sum_{i=2}^{n} e_i y^i = 0$, where the equilibrium points of (2) are related to the solutions of (1). For $n > 2$, the analogue computations of (2) have exhibited in certain situations an oscillation with a small amplitude. The authors use the method of the small parameter in ordinary differential equations to investigate periodic solutions of (2), and the results coincide with experiment. *J. K. Hale* (Providence, R.I.)

Lancaster, P. 6632

Bounds for latent roots in damped vibration problems.
SIAM Rev. **6** (1964), 121–125.

This paper is concerned with obtaining bounds on the natural frequencies and rates of decay of the free vibrations of lightly damped systems of the type $A\ddot{\mathbf{q}} + \varepsilon B\dot{\mathbf{q}} + C\mathbf{q} = 0$, where ε is a scalar parameter and (1) $\mathbf{q}$ is a real n-column vector; (2) A, B and C are real symmetric $n \times n$ matrices, A is positive definite and B and C are at least non-negative definite. The problem is reduced to that of obtaining bounds on the latent roots of the algebraic equations $(\lambda^2 I + \varepsilon\lambda\beta + w^2)\mathbf{p} = 0$, where $\beta = \varphi' B\varphi$, $w^2 = \varphi' C\varphi$, φ being the real congruent matrix which simultaneously diagonalizes A and C and which is normalized so that $\varphi' A\varphi = I$. Using the well-known Geršgorin theorem, the author shows that (i) $-\varepsilon\beta_n \leq \operatorname{Re} \lambda_r \leq 0$, $r = 1, 2, \cdots, n$. In the case where ε is sufficiently small, and the undamped natural frequencies, w_{r0}, are all distinct, nonzero, and well-separated, the author shows that $\lambda_r = iw_{r0} - \frac{1}{2}\varepsilon\beta_{rr} + O(\varepsilon^2)$, $r = 1, 2, \cdots, n$. If the latent roots are all complex, the author is able to show that the eigen-equation yields sharper bounds than the Geršgorin theorem, namely, (ii) $-\frac{1}{2}\varepsilon\beta_n \leq \operatorname{Re} \lambda_i \leq 0$, $i = 1, 2, \cdots, n$; (iii) $|\lambda_i| \leq w_{n0}$, where β_n is the largest eigenvalue of β and w_{n0} is the largest undamped natural frequency.

It should be pointed out that the technique used by the author is capable of yielding even sharper bounds, in fact, (ii) and (iii) should read (iia) $-\frac{1}{2}\varepsilon\beta_n \leq \operatorname{Re} \lambda_i \leq -\frac{1}{2}\varepsilon\beta_1$; (iiia) $w_{10} \leq |\lambda_i| \leq w_{n0}$, $i = 1, 2, \cdots, n$, where β_n and β_1 are the largest and smallest eigenvalues of β, and w_{n0} and w_{10} are the largest and smallest undamped natural frequencies of the system. *T. ★Numerical aspects of the one-dimensional diffusion equation. (Dutch summary)
Proefschrift ter Verkrijging van de Graad van Doctor in de Technische Wetenschappen aan de Technische Hogeschool te Delft. Delft, 1964. vii + 88 *pp.*

A special analog computer is introduced and applied to solve the quasi-linear parabolic system $\partial z_i/\partial t - a_i\partial^2 z/\partial x^2 = f_i(x, t, z_1, z_2, \cdots, z_n)$, $a_i > 0$, $z_i(0, t) = \phi_i(t)$, $z_i(1, t) = \eta_i(t)$, $z_i(x, 0) = \gamma_i(x)$, $i = 1, 2, \cdots, n$. The quasi-linear equations are transformed to a difference form based on the concepts of "external" and "internal" solutions. The x-external solution z_e (generalization of the "steady state solution") for the homogeneous parabolic problem $z_t - z_{xx} = 0$, $z(0, t) = \phi(t)$, $z(1, t) = \eta(t)$, and $z(x, 0)$ is defined by

$$z_e(x, t) = \sum_{0}^{\infty} \{g_k(x)\phi^{(k)}(t) + g_k(1-x)\eta^{(k)}(t)\},$$

where the $g_k(x)$ are odd polynomials in $(1-x)$ of degree $2k+1$. Since the external solution is not generally the solution of the problem, the difference between the solution and the external solution is defined as the "internal" solution.

The choice of a finite-difference approximation is discussed via a general Crank-Nicolson implicit method [see Forsythe and Wasow, *Finite-difference methods for partial differential equations*, p. 119, Wiley, New York, 1960; MR **23** #B3156]. The error in various approximations is computed. For small values of u in the growth factor $g_n = [1 + (1-a)u](1 - au)^{-1}$, the difference expression of Crank-Nicolson (with $a = \frac{1}{2}$) is the best one. For large values of $|u|$ the Laasonen system ($a = 1$) is best. Other special forms are also considered.

Gunn, James E. 6636

The numerical solution of $\nabla \cdot a\nabla u = f$ by a semi-explicit alternating-direction iterative technique.
Numer. Math. **6** (1964), 181–184.

In the numerical solution of Dirichlet's problem for Poisson's equation on a rectangle by the standard five-point difference scheme, one is led to an (unusually large) system of linear equations $A_0 u = f$, where A_0 is a positive-definite symmetric matrix. One of the most effective methods for the solution of this linear system is the alternating direction method of Peaceman-Rachford. For

more general elliptic equations (self-adjoint) one obtains a linear system $Au=f$ for which the full force of the Peaceman-Rachford method has not been analyzed. E. G. D'jakonov [Dokl. Akad. Nauk SSSR **138** (1961), 522–525; MR **25** #767] proposed the iterative scheme $A_0u^{n+1}=A_0u^n-\rho(Au^n-f)$, where ρ is a positive constant and u^{n+1} is approximated by the Peaceman-Rachford process, essentially carried to completion. For this iterative process there is a $\rho>0$ such that a norm of the error is reduced by a factor ε in $O(h^{-2}(\log h)^2 \log \varepsilon)$ arithmetic operations, where h is the mesh spacing. In this paper the author shows that there is a $\rho>0$ such that if only one cycle of the Peaceman-Rachford process is performed in the calculation of u^{n+1}, then a norm of the error is reduced by a factor ε in $O(h^{-2}\log h^{-1}\log \varepsilon)$ arithmetic operations. An estimate is also given for the percentage increase in arithmetic operations over that needed to solve $A_0u=f$. *M. Lees* (Pasadena, Calif.)

Gunn, James E. 6637

On the two-stage iterative method of Douglas for mildly nonlinear elliptic difference equations.

Numer. Math. **6** (1964), 243–249.

The transformation $v=a^{1/2}u$ reduces the elliptic differential equation $-\nabla\cdot a(x)\nabla u+\phi(x,u)=0$ to the elliptic equation

$$-\Delta v+\frac{\Delta a^{1/2}}{a^{1/2}}v+a^{-1/2}\phi(x,va^{-1/2})=0,$$

where Δ is the Laplace operator. In this paper the author describes a discrete version of this reduction and investigates an iterative method for solving the resulting nonlinear difference equations for rectangular regions. The iterative method is an important generalization of a two-level iterative method proposed by Douglas [Numer. Math. **3** (1961), 92–98; MR **23** #B2177], in which the inner iteration is of the alternating direction type. An estimate of the arithmetic operations is included. Some weaker results are given for the case of non-rectangular regions.

★Nuclear reactor calculations with the group diffusion equations on digital computers. (Dutch summary)

Proefschrift ter Verkrijging van de Graad van Doctor in de Technische Wetenschappen aan de Technische Hogeschool te Delft, Delft, 1964. x+140 *pp.*

This dissertation deals with the numerical solution of multi-group diffusion equations. There is not a great deal new in these 140 pages, and it is apparent that the writer and his advisors were not too well acquainted with the work that has been carried out at the many atomic energy laboratories.

A standard derivation has been given of the Boltzmann equation and the resulting multi-group diffusion equations. A nine-point finite difference operator is derived as an approximation to the two-dimensional Laplace operator. A discussion of the eigenvalue problem associated with the nine-point operator is presented. The most notable feature of this operator is that it does not possess Young's property A. A computer program for the Burroughs 220 based on the nine-point operator was prepared for a medium sized 2-D multi-group problem.

W. Sangren (San Diego, Calif.)

Lynch, R. E.; Rice, J. R.; Thomas, D. H. 6640

Tensor product analysis of partial difference equations.

Bull. Amer. Math. Soc. **70** (1964), 378–384.

Using tensor products, the authors analyze separable partial difference equations for two-dimensional regions. This allows them to give a compact finite Fourier series type formula for the solution of such difference equations, closely related to the results of Egerváry [Acta Math. Acad. Sci. Hungar. **11** (1960), 341–361; MR **24** #B2559] and J. Heller [J. Soc. Indust. Appl. Math. **8** (1960), 150–173; MR **22** #12705]. Comparisons are then made between the direct (i.e., noniterative) evaluation of this formula and standard iterative methods (SOR and ADI) applied to this separable problem. As is well known, the existing analyses of alternating direction methods depend strongly on the commutativity of two matrix operators H and V: $HV=VH$. The authors then state (without proof) a very interesting necessary and sufficient condition that $HV=VH$ in terms of tensor products, which extends the results of Birkhoff, Varga and Young [Advances in Computers, Vol. 3, pp. 189–273, Academic Press, New York, 1962; MR **29** #5395]. *R. Ein Verfahren zur numerischen Behandlung fastlinearer partieller Differentialgleichungen in Zylinderbereichen. (English and Russian summaries)

Z. Angew. Math. Mech. **43** (1963), 523–532.

Let u denote the solution of an almost linear second-order partial differential equation in a cylindrical region in R^N. Let x_N denote the coordinate in the direction of the axis of the cylinder. Assume that it is possible to choose n linearly independent solutions v_i of the homogeneous adjoint equation. Then

$$u\approx U=\sum_{k=1}^{m}A_k(x_N)w_k(x_1,\cdots,x_N),$$

where w_k, $k=1,\cdots,m$, are known C^1 functions and A_k, $k=1,\cdots,m$, are unknown functions. Equations for the determination of A_k, $k=1,\cdots,m$, are derived with the aid of v_j, $j=1,\cdots,n$, and Green's Theorem. Convergence is discussed and an example is given to demonstrate the procedure. *J. R. Cannon* (Upton, N.Y.)

Sobolev, S. L. 6642

Some new problems in the theory of partial differential equations.

Differential Equations and Their Applications (Proc. Conf., Prague, 1962), pp. 167–177. *Publ. House Czechoslovak Acad. Sci., Prague; Academic Press, New York,* 1963.

Two problems arising in numerical analysis, of determining the value of the integral of a given function $f(x)$ and of finding an approximate procedure for evaluation

of $f(x)$ at a given point from its values on a set of N points, are shown to be adjoint problems. It is possible to consider the error estimation in these numerical procedures as a minimax problem on some functional space. The part of this problem concerned with finding a maximum of the error over the unit sphere in the particular function space considered leads to an extreme function which is the solution of a partial differential equation of elliptic type. In three particular function spaces it is indicated how to derive the differential equation and its solution. The author's purpose is to exhibit "the deep lying connections existing between the theory of partial differential equations and numerical analysis".

Stetter, Hans J. 6643

Maximum bounds for the solutions of initial value problems for partial difference equations.

Numer. Math. **5** (1963), 399–424.

Most of the recent literature on the general stability problem for difference approximations to initial-value problems for partial differential equations is concerned with stability relative to the L^2-norm. In this paper the author investigates the general stability problem, relative to the maximum norm, for multi-step partial difference equations. The results are restricted, essentially, to difference equations with constant coefficients. A sufficient condition (too complicated to state here) for stability in the maximum norm is given in terms of properties of the eigenvalues of the amplification matrix. The results are applied to a number of standard difference schemes for parabolic and hyperbolic differential equations. Results of numerical experiments performed in verification of the theory are also included.

Suschowk, Dietrich 6645

Difference analogues of Green's identities for grids in R^n.

Numer. Math. **6** (1964), 200–210.

Im n-dimensionalen $(x_1, \cdots, x_n)$-Raum R^n sei ein Gitter der Maschenweite h gewählt; $f_{x_j}(P)$ bzw. $f_{\bar{x}_j}(P)$ bezeichnen den vorwärtigen bzw. rückwärtigen Differenzenquotienten einer Gitterfunktion f im Punkte P. Es bedeute $F(u, v)=\sum_{j,k=1}^{n} a_{jk}u_{x_j}v_{x_k}$ für zwei Gitterfunktionen u, v bei gegebenen Gitterfunktionen a_{jk}. $E(u, v)$ entsteht aus $F(u, v)$ durch Hinzunahme von bilinearen Gliedern, die in u, v und ihren ersten Differenzenquotienten linear sind, aber keine Produkte von Differenzenquotienten enthalten. Nach sorgfältiger Festlegung des "Randes" eines zusammenhängenden "Gitterbereiches" G werden die finiten Analoga zu den beiden bekannten Greenschen Formeln aufgestellt, die eine Umformung von $\sum_{P\in G} E(u, v)(P)$ und von Summen über Ausdrücke $u(a_{kj}v_{x_j})_{\bar{x}_k}-v(a_{jk}u_{x_j})_{\bar{x}_k}$ gestatten.

An Figuren im R^3 wird erläutert, welche Gitterpunkte jeweils in den Greenschen Identitäten auftreten.

Tee, G. J. 6646

A novel finite-difference approximation to the biharmonic operator.

Comput. J. **6** (1963/64), 177–192.

The author considers the solution by finite-difference methods of problems involving the biharmonic equation where the values of the solution and of its normal derivative are specified on the boundary of a region in two dimensions. He considers three finite-difference representations of the biharmonic operator, including the usual 13-point representation, as well as two 17-point representations. Both of the 17-point representations lead to matrices having Property A [the reviewer, Trans. Amer. Math. Soc. **76** (1954), 92–111; MR **15**, 562]. This greatly facilitates the use of the successive overrelaxation iterative method (S.O.R. method) for solving the linear system arising from the difference equation. However, the author does not appear to be aware of Kahan's results which show that even without Property A one can use the S.O.R. method effectively, provided that the diagonal elements of the matrix are positive and all other elements are nonpositive. (Kahan's work is unpublished, but a very brief summary is given on page 407 in a chapter (by the reviewer) of the book, *A survey of numerical analysis* [pp. 380–438, McGraw-Hill, New York, 1962; MR **24** #B2123].) Actually, however, in all three cases considered by the author the matrices do not satisfy Kahan's properties.

One of the 17-point representations was considered by Henrici in 1960 in an unpublished memorandum. The other was introduced by the author in order to achieve stronger diagonal dominance, but at the cost of using mesh points more distantly placed from the center point. For his procedure the author shows that, under certain assumptions, the local truncation error, the convergence rate of the S.O.R. method, and the truncation error of the finite-difference solution are all of order $O(h^2)$ as $h\to 0$. The 13-point formula leads to somewhat smaller truncation errors, but based on numerical experiments, the convergence of the S.O.R. method appears to be several times slower. The convergence rate of the S.O.R. method using the author's 17-point representation appears to be slightly faster than that obtained using the other 17-point representation.

Some remarks on the stability of iteration processes. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 745–748.

The stability of the iterative process

(1) $$X^{(n+1)} = AX^{(n)} + B$$

for the solution of the finite linear system $X = AX + B$ with respect to round-off error is studied. All numbers involved are assumed to be fixed point fractions, s digits in length, with radix b. It is also assumed that the row norm $\|A\|$ of the matrix A is less than or equal to one, and that (1) converges if $\|A\| = 1$. The process (1) is said to be really stable if s_1 digits of each component of the result of the mth iteration can be guaranteed to be accurate for some m, with $0 < s_1 < s$. Simple conditions for real stability involving m and the order n of A are given, and applied to find a lower bound for the mesh length for the solution of the Dirichlet problem for Poisson's equation for which the Liebmann method will be really stable. *L. Generalization of Steffensen's method for operator equations.

Comment. Math. Univ. Carolinae **5** (1964), 47–77.

Das Verfahren von Steffensen

$$x_{n+1} = Fx_n + \delta F(Fx_n, x_n)(x_{n+1} - x_n),$$

eine Zusammenfassung von gewöhnlicher Iteration und der Regula falsi, wird derart verallgemeinert, daß es zur iterativen Lösung von Fixpunktgleichungen $x = Fx$ im Banachraum geeignet ist. Dabei wird die zur Beschreibung des Verfahrens benötigte Steigung δF in der vom Referenten vorgeschlagenen Weise [J. W. Schmidt, Z. Angew. Math. Mech. **43** (1963), 1–8; MR **26** #5442; ibid. **43** (1963), 97–110; MR **27** #616] als linearer beschränkter Operator erklärt, der gewissen Forderungen genügt. Es werden verschiedene Sätze angegeben, welche neben der Existenz einer Lösung die Konvergenz des Verfahrens sichern und eine Fehlerabschätzung erlauben. Man kann ablesen, daß die Konvergenzgeschwindigkeit quadratisch ist. Die stets geforderte Kontraktionsbedingung an F läßt sich vermutlich noch abschwächen. Als Abschluß wird ausführlich auf die Anwendung der allgemeinen Theorie auf Systeme von nichtlinearen Gleichungen und auf nichtlineare Integralgleichungen eingegangen. *J. W. Schmidt* (Dresden)

Miellou, Jean-Claude 6650

Un procédé récurrent de calcul de la solution des problèmes aux limites variationnels elliptiques, linéaires, sous-forme d'un développement en série.

C. R. Acad. Sci. Paris **256** (1963), 1438–1440.

Let H be a Hilbert space with inner product $(\cdot,\cdot)$ and the associated norm $|\cdot|$. Let V be a linear subspace dense in H. On V, let a second inner product $((\cdot,\cdot))$ and its associated norm $\|\cdot\|$ be given, such that the two norms are topologically equivalent on V. Let B be a bilinear form (not necessarily symmetric) defined on $V \times V$ such that $|B(u,v)| \le c_1\|u\|\cdot\|v\|$ and $B(v,v) \ge c_2\|v\|^2$ for all $u, v \in V$. Given $f \in H$, in order to find $u \in V$ satisfying (1) $B(u,v) = (f,v)$ for all $v \in V$, the author observes that from any basis of V, another basis $\{e_i\}$ of V can be constructed such that $B(e_i, e_i) = 1$ and $B(e_i, e_j) = 0$ for $i > j$. Then the expansion of the solution u of (1) in the basis $\{e_i\}$ can be obtained by solving an infinite lower triangular system of linear equations. *Ky Fan* (Evanston, Ill.)

Miellou, Jean-Claude 6651

Remarques sur l'application de la méthode de Galerkin aux problèmes aux limites elliptiques variationnels, linéaires.

C. R. Acad. Sci. Paris **256** (1963), 3946–3948.

Let V be a closed linear subspace of the Sobolev space $H^m(\Omega)$ such that V contains all infinitely differentiable functions on Ω with compact support. Let B be a bilinear form defined on $V \times V$ such that $|B(u,v)| \le c_1\|u\|\cdot\|v\|$ and $B(v,v) \ge c_2\|v\|^2$ for all $u, v \in V$. Consider a basis $\{w_n\}$ of V and denote by V_n the linear subspace spanned by $\{w_1, w_2, \cdots, w_n\}$. For $f \in L^2(\Omega)$, let u_n be the unique vector in V_n satisfying $B(u_n, v) = (f, v)$ for all $v \in V_n$. The main result states that $\{u_n\}$ converges strongly to the unique $u \in V$ satisfying $B(u,v) = (f,v)$ for all $v \in V$. Several estimates of the error $\|u - u_n\|$ are also given. *Ky Fan* (Evanston, Ill.)

Petryshyn, W. V. 6652

On the generalized overrelaxation method for operation equations.

Proc. Amer. Math. Soc. **14** (1963), 917–924.

The well-known necessary and sufficient condition for the convergence of the Gauss-Seidel iterative method ($\omega = 1$) due to Reich [Ann. Math. Statist. **20** (1949), 448–451; MR **11**, 136] was generalized by Ostrowski [Rend. Mat. e Appl. (5) **14** (1954), 140–163; MR **16**, 1155] who analogously gave a necessary and sufficient condition for the successive overrelaxation iterative method ($0 < \omega < 2$). More recently, Kreĭn and Prozorovskaja [Voronež. Gos. Univ. Trudy Sem. Funkcional. Anal. **5** (1957), 35–38; MR **20** #2081] extended Reich's result to operator equations of the form $(D - S - S^*)u = f$ in a Hilbert space. Although apparently unaware of Ostrowski's work, the author similarly extends Ostrowski's result by giving a necessary and sufficient condition that the successive overrelaxation method be convergent in a Hilbert space, using the notions of K-positive definite operators and K-symmetric operators introduced by the author [Trans. Amer. Math. Soc. **105** (1962), 136–175; MR **26** #3180]. *R. S. Varga* (Cleveland, Ohio)

Poljak, B. T. 6653

Some methods of speeding up the convergence of iterative methods. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 791–803.

Consider the functional equation $P(x) = 0$, where P is an operator on a Banach space B with range in B. Most methods for solving this equation consist in forming a sequence $x^n \in B$ which converges to the desired solution x^* as $n \to \infty$. Continuous analogues of these methods are also known, whereby a trajectory $x(t)$ in B is obtained such that $x(t) \to x^*$ as $t \to \infty$. The present paper deals with the convergence of two such methods. The first, discrete, method generates the sequence $\{x^n\}$ by a k-step iteration of the form

(1) $$x^{n+1} = \sum_{i=0}^{k-1} \alpha_i x^{n-i} + \sum_{i=0}^{k-1} T_{i+1} P(x^{n-i}),$$

where α_i are numerical constants satisfying $\sum_{i=0}^{k-1} \alpha_i = 1$, and T_{i+1} are continuous linear operators. The second method defines the trajectory $x(t)$ as a solution of a kth-order differential equation in B,

$$(2)\quad d^k x/dt^k = T_1(d^{k-1}x/dt^{k-1}) + \cdots + T_{k-1}(dx/dt) + T_k P(x).$$

The main result relating to (1) is as follows. Let x^* be a solution of $P(x) = 0$, and let P be Fréchet-differentiable at x^*, with derivative $U = P'(x^*)$. Assume, moreover, that the operators $T_1, \cdots, T_k$ commute with each other, and with U. Denote by $\rho_1, \cdots, \rho_k$ the roots of the algebraic equation $\rho^k = \sum_{i=0}^{k-1} (\alpha_i + \lambda_{i+1}\lambda)\rho^i$, where λ is in the spectrum $\sigma(U)$ of U, and λ_i in $\sigma(T_i)$. Let

$$\sup_{\lambda, \lambda_i} \max_s |\rho_s| \leq q < 1,$$

where the supremum is taken over the respective spectra. Then, for arbitrarily small $\varepsilon > 0$, one has $\|x^n - x^*\| = O((q+\varepsilon)^n)$ as $n \to \infty$, provided the initial elements $x^0, x^1, \cdots, x^{k-1}$ are sufficiently close to x^*. An entirely analogous result is obtained for (2). In the special case of a linear equation $Ax - b = 0$ (A a continuous linear operator), convergence can be established for arbitrary initial elements. More detailed results are presented for the case where P is the gradient of a functional in a Hilbert space, and the methods have the special form

$$x^{n+1} = x^n - \alpha P(x^n) + \beta(x^n - x^{n-1}),$$

$$d^2x/dt^2 = \alpha_1(dx/dt) + \alpha_2 P(x).$$

Convergence of these two-step methods ($k = 2$) is shown in certain situations to be substantially faster than the convergence of corresponding one-step methods.

Tihonov, A. N.; Glasko, V. B. 6654

An approximate solution of Fredholm integral equations of the first kind. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 564–571.

The method of regularization developed by A. N. Tihonov [Dokl. Akad. Nauk SSSR **151** (1963), 501–504; MR **28** #5576; ibid. **153** (1963), 49–52; MR **28** #5577] is applied numerically to the Fredholm equation of the first kind,

$$\int_{-1}^{1} K(x, s)z(s)\,ds = u(x), \qquad -1 \leqq x \leqq 1,$$

with

$$K(x, s) = \frac{1}{\pi}\{(x-s)^2 + 1\}^{-1}.$$

Using the case with known solution $z(s) = (1-s^2)^2$, the optimum value of the regularization parameter for minimum error is determined experimentally. Without regularization, the error in the numerical solution is about 10^6 in magnitude, even though the residue is 10^{-8} in magnitude. Use of regularization with the optimum parameter reduces the error to about 10^{-3}. The effect of perturbation of $u(x)$ on the error is studied empirically for the original equation, and also for the case that the integration extends over some smaller interval $-k \leqq s \leqq k$ with $k < 1$. In the latter case, the conclusion is that the numerical solution is unstable with respect to errors in $u(x)$ even for optimum regularization.

L. B. Rall (Madison, Wis.)

Twomey, S. 6655

On the numerical solution of Fredholm integral equations of the first kind by the inversion of the linear system produced by quadrature.

J. Assoc. Comput. Mach. **10** (1963), 97–101.

This paper has been listed by title in MR **26** #5757. The numerical solution of linear Fredholm integral equations of the first kind presents great difficulties and severely limits the usefulness of such equations in describing physical phenomena. Upon use of a quadrature formula the original equation is approximated by a system of linear algebraic equations, $Ax = g$, but frequently the exact solution of this system, x, has properties which conflict with our a priori knowledge. For example, the components of x may oscillate wildly, whereas the solution of the original integral equation may be quite smooth, even monotone. The author (and in an earlier paper D. L. Phillips [J. Assoc. Comput. Mach. **9** (1962), 84–97; MR **24** #B534]) suggests replacing the linear algebraic system by various minimization problems, e.g.,

$$\min_x [(x - c, x - c) + \lambda(Ax - g, Ax - g)],$$

where c is a preliminary estimate of x, and several values of the parameter λ are to be examined.

The point is that we should incorporate all of our knowledge of the physical situation before attempting to solve a system of possibly ill-conditioned linear algebraic systems. For a further discussion, in which the components of x are determined sequentially using dynamic programming, reference may be made to a report by Bellman, the reviewer and Lockett [RAND Rep. RM-3815-PR (1963)].

Olver, F. W. J. 6656

Error analysis of Miller's recurrence algorithm.

Math. Comp. **18** (1964), 65–74.

This paper is concerned with a device for computing accurately, from a second-order linear homogeneous recurrence relation, a solution which diminishes to zero as the argument becomes infinite, from a given starting value and in the presence of another solution that increases indefinitely relatively to the desired solution.

The method is to use the recurrence relation in the reverse direction, with more or less arbitrary starting values (but chosen in such a way that the desired solution is not swamped by the unwanted one), at an argument large enough so that, on working backwards, the unwanted solution dies away to relative insignificance before any argument is reached for which a final solution is desired.

The author discusses the error analysis of this process, with particular attention to the rounding-errors inevitable at every stage of the process, and the final normalisation whereby the results of backward recurrence are collated with the given "starting" value, which is in general at the final argument reached.

Büchi, J. Richard 6660

Regular canonical systems.

Arch. Math. Logik Grundlagenforsch. 6, 91–111 (1964).

The systems of the title are those involving rules of production of the form $aP \to bP$ only. The author studies the sets of words derivable from finitely many axioms, together with finitely many such rules of production. One of his main results is that such sets are the accepted sets of automata. (His other results are mainly concerned with alternate characterizations of such sets.) Chomsky [Information and Control 2 (1959), 137–167; MR 21 #4107] showed that a one-sided linear language is equivalent to an accepted set; a footnote in the paper under review, however, fixes the original publication of this material (as a report of the University of Michigan) at the same time. [The printers seem to have applied a semi-Thue system to the text, and the editors seem to have taken the result as an accepted set; on p. 93, e.g., in Definition 1 the union and intersection symbols should be switched, in line 12 the u_i, should be u_{i+1}, and in line -6 all arrows should be translated one symbol to the right, etc.]

R. M. Baer (Berkeley, Calif.)

Cyprus, Joel Howard 6661

Optimal synthesis of the Boolean functions of four variables with majority logic.

Rice Univ. Studies 50 (1964), no. 2, v+110 pp.

The author considers the synthesis of Boolean functions by majority and minority logic. Restricting attention to four or fewer variables, these functions are decomposed into equivalence classes under the group consisting of complementations and permutations of the variables and functional complementation. Under this group, the 65,536 Boolean functions of four variables fall into 222 equivalence classes. For each class the author finds an optimal realization of a representative function by an exhaustive search using a digital computer.

The more difficult problem of efficiently determining if a given function is equivalent to a representative is sidestepped by listing all the functions of fewer than four variables with their equivalent representatives.

The extensive tables (57 pages) will prove useful to logical designers, while the lucid discussion may be of interest to those interested in programming logical problems.

M. A. Harrison (Berkeley, Calif.)

Lindamood, George E.; Shapiro, George 6662

Magnitude comparison and overflow detection in modular arithmetic computers.

SIAM Rev. 5 (1963), 342–350.

Modular arithmetic, in which an integer is represented by its residues with respect to a set of relatively prime moduli, would permit addition and multiplication to be executed in digital computers with comparative ease and speed, since "carry's" do not have to be performed. Unfortunately, other operations are more cumbersome in modular arithmetic than in the conventional radix notation. Two such operations are magnitude comparison and overflow detection. In this paper, the authors present methods for performing these two operations using only the basic modular arithmetic operations of addition, subtraction, multiplication and comparison of residues.

Magnitude comparison is effected by the rather interesting technique of converting the residue representation of an integer x with respect to moduli $r_0, \cdots, r_{n-1}$ into a "mixed radix" representation of the form

$$x = a_n(r_{n-1} \cdots r_0) + a_{n-1}(r_{n-2} \cdots r_0) + \cdots + a_1 r_0 + a_0,$$

with $0 \le a_i < r_i$. *E. K. Blum* (Middletown, Conn.)

Using machine code within an ALGOL system.

Nordisk Tidskr. Informations-Behandling 4 (1964), 115–117.

Author's summary: "The use of machine code within programs run in the GIER ALGOL system is made possible through the provision of standard procedures which transfer the control of the machine to the instruction held as a variable of the ALGOL program. The paper describes these and some associated standard procedures."

F. L. Bauer (Munich)

Naur, Peter 6664

The design of the GIER ALGOL compiler. I, II.

Nordisk Tidskr. Informations-Behandling 3 (1963), 124–140; *ibid.* 3 (1963), 145–166.

A detailed, clear and instructive description of the ALGOL compiler for the Danish computer GIER, a medium size computer with a core store of only 1024 words of 42 bits

and a backing magnetic drum of 12,800 words. The resulting multipass compiler has 9 passes and occupies 5199 words; organization of these passes is nearly optimal under the conditions given by the non-homogeneous store. Parsing techniques and especially questions of the running system: storage allocation, addressing, procedure calling are thoroughly discussed; whenever possible, reasons for the solution adopted are given and connections to methods used elsewhere are mentioned. Thus, this study is exemplary in its presentation, and the GIER ALGOL compiler demonstrates the practicability of ALGOL translation even for a smaller computer. *F. L. Bauer* (Munich)

★Computer programming: A mixed language approach.
Academic Press, New York-London, 1964. xiv + 459 *pp.* $11.50.

This book is a text on digital computer programming. The authors take the view that it is logically and pedagogically sound to begin such a text with a discussion of machine language programming. Accordingly, they do this with the CDC 1604 as the machine for illustration. They proceed through the usual elementary chapters on (1) Number systems, (2) Machine organization, (3) Elementary coding, (4) Fixed and floating point arithmetic, (5) Nonarithmetic operations, in some 214 pages. This brings them to the first sophisticated idea in programming, the subroutine, which they treat in a quite ad hoc and inadequate fashion in a twenty-page Chapter 6. In Chapter 7, "Input-output" is treated briefly. Chapter 8 is entitled "Assembly of complete programs," Chapter 9, "FORTRAN; mixed language programs"; there is a further discussion of subroutines.

The reviewer questions the authors' suggestion that the book is suitable for the "junior, senior, and early graduate level". Certainly, material as elementary as this can and should be presented at lower levels. There are aspects of programming that are appropriate for the higher levels, but these are not approached in this text.

Stein, P. R.; Ulam, S. M. 6666

Non-linear transformation studies on electronic computers.
Rozprawy Mat. **39** (1964), 66 *pp.*

This is a paper in the field of experimental mathematics using arithmetic. Experimental mathematics has always been widely practiced, but essentially only the arithmetic branch, centered around number theory, has achieved any status worth mentioning. The modern electronic computer is a handy sorcerer's apprentice for those who would enter the field.

The paper considers mainly the three-dimensional iteration transformations

$$x_i = P_i(x_1, x_2, x_3), \qquad i = 1, 2, 3,$$

where the P_i are cubics in x_1, x_2, x_3. Some related transformations are also discussed. Many photographs of cathode ray tube displays are given, a fondness for citing large numbers of iterations and machine time used is revealed, and a crude classification of the limited results is offered, but there appear to be no firm new results of general mathematical interest.

It is an attractive idea that computers can produce many specific cases of mathematical situations from which we can obtain insight, but usually (though not always) it is the insight, not the specific cases, that has been the criterion for public presentation. One can only wonder what will happen to mathematics if we allow the undigested outputs of computers to fill our literature. The present paper shows only slight traces of any digestion of the computer output.

GENERAL APPLIED MATHEMATICS

Comstock, Craig 6667

On the autocorrelation of random inhomogeneities.
J. Acoust. Soc. Amer. **36** (1964), 1534–1536.

The author treats singularities at the origin of temperature fluctuation autocorrelation functions. The usual autocorrelation function $N(\rho)$ is decomposed into two functions $N(\rho|a)$ and $g(a)$, the former representing the autocorrelation function for scattering regions of fixed size a while $g(a)$ is a probability density function for the inhomogeneity size a. By a particular choice of form of $N(\rho|a)$ and $g(a)$, both analytic at the origin, it is shown that a family of functions $N(\rho)$, none of which is analytic at the origin, may be constructed. By suitable choice of $g(a)$, a useful $N(\rho)$ may be generated which, the author concludes, will shed light on the physics of the process involved. *G. E. Lord* (Seattle, Wash.)

On the dynamic stability of a sinusoidal arch. (Russian. Armenian summary)

Izv. Akad. Nauk Armjan. SSR Ser. Fiz.-Mat. Nauk 17 (1964), no. 4, 23–33.

Die Differentialgleichungen für die Biegeschwingungen eines Trägers mit sinusförmig gekrümmter Mittellinie und sinusförmiger Belastungwerden aufgestellt und durch einen Separationsansatz vereinfacht. Bei periodisch wechselnder Last führt die Berechnung des Zeitverhaltens auf eine Differentialgleichung vom Mathieu'schen Typ, deren Beiwerte aus den Randbedingungen zu bestimmen sind. Für zwei spezielle Fälle werden sie ausgerechnet: für einen beidseitig gelenkig gelagerten und für einen beidseitig fest eingespannten Träger. Dabei wird das Galerkin'sche Näherungsverfahren verwendet, um kritische Belastungen und Eigenfrequenzen zu erhalten. Diese Näherungswerte erlauben die Bestimmung der Grenzen der instabilen Bereiche. Der Vergleich mit bekannten Ergebnissen, die für Träger mit parabolisch gekrümmten Mittellinien erhalten wurden, zeigt nur geringe Unterschiede für beide Trägerformen. *K. Magnus* (Stuttgart)

The effect of high-frequency perturbations on the resonance vibrations in a non-linear system. (Russian)

Leningrad. Politehn. Inst. Trudy No. 226 (1963), 7–17.

Consider the equation

$$(1)\qquad \ddot{x}+g(\dot{x})+f(x) = F(t),$$

where x denotes the displacement, $g(\dot{x})$ the dissipative force, $f(x)$ the restoring force and $F(t)=A\sin\nu t+B\sin\omega t$, $\omega\gg\nu$, the external force. Following the method of harmonic linearization the solution of (1) is sought in the form (2) $x=x_0+b\sin(\omega t+\varphi)$, where x_0 is a slowly varying function. Upon substitution of (2) into (1) and separation of the slowly varying terms from the first harmonics of vibration with frequency ω, two equations are obtained. The influence of high-frequency perturbations on resonance vibrations is investigated for several particular systems, such as, for example, a system with linear elastic characteristic and dry friction, a system with viscous friction and cubic characteristic, and so on.

Nonlinear theory of simple micro-elastic solids. I. (French, German, Italian and Russian summaries)

Internat. J. Engrg. Sci. 2 (1964), 189–203.

Authors' summary: "The present work is concerned with the formulation of the basic field equations, boundary conditions and constitutive equations of what we call 'simple micro-elastic' solids. Such solids are affected by the 'micro' deformations and rotations not encountered in the theory of finite elasticity.

"The theory, in a natural fashion, gives rise to the concept of stress moments, inertial spin and other types of second-order effects and their laws of motion. The mechanism of the surface tension is contained in the theory. In a forthcoming paper (Part II) explicit expressions of constitutive equations of several simple micro-elastic solids will be given and applied to some special problems."

Boundary-value problems for the vibration of an infinite, two-dimensional, non-homogeneous, elastic isotropic body. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR 35 (1964), 531–538.

In this paper (following earlier work by V. D. Kupradze,

M. O. Bašeleĭšvili and others), a proof is given of the existence theorem for problems of the vibration of an infinite, plane, piecewise inhomogeneous, isotropic, elastic body. The techniques used involve applications of potential theory, and no restriction is placed upon values of either the frequency or elastic constants.

H. G. Hopkins (Sevenoaks)

Bašeleĭšvili, M. O. 6677

Solution of the third and fourth boundary-value problems in the statics of an anisotropic elastic body. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **35** (1964), 277–284.

This paper concerns the same problems discussed in an earlier paper by the author [same Soobšč. **34** (1964), 283–290; MR **29** #5437], their solutions now being derived by means of different techniques involving Fredholm integral equations. Thus, existence theorems are proved for the solutions of the third and fourth boundary-value problems for simply connected finite and infinite regions. It is stated that the extension to multiply connected regions involves no analytical difficulty. Furthermore, it is stated that similar analysis can be developed for the theory of bending of anisotropic plates. *H. G. Hopkins* (Sevenoaks)

Kvinikadze, G. P. 6678

Existence theorems for the exterior third and fourth dynamics problems of elasticity theory. (Russian. Georgian summary)

Soobšč. Akad. Nauk Gruzin. SSR **33** (1964), 293–300.

The third and fourth boundary-value problems of the dynamic plane theory of elasticity, as defined by V. D. Kupradze in his book, *Boundary problems of the theory of vibrations and integral equations* (Russian) [GITTL, Moscow, 1950; MR **15**, 318] are discussed for the case when

$$\sqrt{r}\,u_j = O(1), \quad \sqrt{r}\,(\partial u_j/\partial r - ik_j u_j) = o(1), \qquad j = 1, 2,$$

as $r \to \infty$. Uniqueness of the solutions is proved and the problems are reduced to singular integral equations, the solutions of which are studied.

Parasjuk, E. N. 6680

On a theorem of Tamarkin type and its application to the second fundamental problem of two-dimensional elasticity theory. (Russian)

Ukrain. Mat. Ž. **16** (1964), 537–538.

The following theorem is proved and discussed with regard to elasticity. Suppose that for the equation

$$(1) \qquad u(x, \lambda) - \int_S K(x, y; \lambda) u(y, \lambda)\, d_y S = f(x, \lambda)$$

(S = a surface) the following conditions are satisfied: (a) The kernel $K(x, y; \lambda)$ and the function $f(x, \lambda)$ are analytic functions of λ in a domain D of the λ-plane; (b) The kernel $\partial K/\partial\lambda$ is of the same type as K, in particular, an integral operator with this kernel is bounded in some Banach space; (c) For each $\lambda \in D$, (1) has a unique solution. Then each solution of (1) for $\lambda \in D$ is an analytic function of λ in D. *J. Nowinski* (Newark, Del.)

Zorski, Henryk 6682

On the equations describing small deformations superposed on finite deformation.

Second-order Effects in Elasticity, Plasticity and Fluid Dynamics (Internat. Sympos., Haifa, 1962), *pp.* 109–128. *Jerusalem Academic Press, Jerusalem; Pergamon, Oxford,* 1964.

Conditions of ellipticity and strong ellipticity are derived and discussed for the field equations appropriate to the theory of small deformations superposed on large deformations of elastic isotropic solids. The particular finite deformations of simple shear, extension, and torsion of a circular cylinder are used as examples to show what sort of restrictions the assumed existence of superposed displacements will impose on the strain energy function and the initial finite deformation field. The results are presented in the form of inequalities, and for the case where the material is a Mooney material or, more generally, where the strain energy function depends only on the first powers of the principal strain invariants, it is shown that simple, physically meaningful restrictions appear.

General questions of uniqueness, existence and stability are briefly treated, and requirements sufficient to insure each of these properties are compared.

On finite thermal deformations. (Polish and Russian summaries)

Arch. Mech. Stos. **16** (1964), 103–108.

The authors present a differential-geometric discussion concerning the deformations in a material which are induced by an arbitrary temperature field without treating the thermodynamic aspects of the problem. They recall that in the usual linear theories treating thermal deformations the total (compatible) strain is represented as the sum of two incompatible strains; the thermal strain and the elastic strain. Since this decomposition is not generally possible in the nonlinear theories, the authors introduce a model for treating the incompatible deformations, which has found application in the continuum theory of dislocations. Finally, the authors remark that the stress state of a thermally deformed body is described, in general, by the stress tensor field σ^{ij} and the couple stress tensor field τ^{ijk}, and briefly mention the equations which are available in order to find the unknown deformations in any given problem. *R. L. Fosdick* (Chicago, Ill.)

Verma, P. D. S. 6686

Electrical conduction in finitely deformed isotropic materials. (Polish and Russian summaries)

Arch. Mech. Stos. **15** (1963), 3–6.

An attempt is made to write down the form taken by the constitutive equation for electrical conduction in deformed isotropic materials, in the special case of a spherically symmetrical deformation. It is unaccountably assumed that only one strain component is different from zero in such a deformation. Consequently, the attempt fails. *A. C. Pipkin* (Providence, R. I.)

Note sur l'équilibre élastique d'un milieu indéfini percé d'une cavité cylindrique sous pression. (English summary)

Ann. Ponts Chaussées **134** (1964), 473–521.

Author's summary: "Faisant suite à une précédente étude qui portait sur une cavité cylindrique percée en milieu semi-indéfini et soumise à une pression constante, l'auteur

étudie ici l'état de contrainte et de déformation d'un milieu indéfini au voisinage d'une cavité cylindrique soumise à une pression non constante, mais présentant une symétrie de révolution par rapport à l'axe de la cavité. La solution de ce problème s'exprime par des séries ou intégrales de Fourier faisant intervenir des fonctions de Bessel modifiées. Elle s'applique plus généralement au cas de plusieurs milieux annulaires concentriques de caractéristiques mécaniques différentes. On peut étendre cette solution aux cas réels de galeries souterraines sous pression moyennant, d'une part une certaine approximation, d'autre part des précautions dans le choix des paramètres des séries de Fourier."

Guz', O. M. 6693
Representation of solutions of three-dimensional axisymmetric problems of elasticity theory for a transversely isotropic body. (Ukrainian. Russian and English summaries)
Dopovidi Akad. Nauk Ukraïn. RSR **1963**, 1592–1595.

In the problem of the title displacements and stresses are expressed by derivations of two functions satisfying the following differential equations of second order:

$$(\partial^2/\partial r^2 + r^{-1}\,\partial/\partial r + \nu_j^2\,\partial^2/\partial z^2)\varphi_j = 0 \qquad (j = 1, 2).$$

In the case of real parameters ν_j, the functions φ_j become harmonic in two different regions obtained by affine transformation of the region considered. No illustrative examples are given. *Z. Kączkowski* (Warsaw)

Herrmann, L. R. 6694
Stress functions for the axisymmetric, orthotropic, elasticity equations.
AIAA J. **2** (1964), 1822–1824.

The author extends Southwell's stress function solution of the torsionless axisymmetric problem of isotropic and homogeneous linear elasticity to the case of cylindrical orthotropy with body force and temperature effects. The resulting solution is in terms of two stress functions which must satisfy a pair of coupled second-order partial differential equations. It follows from the method of introduction of the stress functions that the solution is complete in regions which meet certain convexity requirements.

Attia, M. S.; Nassif, M. 6695
Transverse bending of a thin circular plate eccentrically loaded and supported along a concentric circle.
Bull. Calcutta Math. Soc. **54** (1962), 131–150.

Complex potentials are used to solve the biharmonic equation for the deflection of an elastic plate, simply supported and subjected to a point load.

For a circular plate supported round a concentric circle, the result is given as a Fourier series. For the simpler case of an infinite plate the result appears in closed form.
J. W. Craggs (Melbourne)

Tomar, J. S. 6696
On flexural vibrations of isotropic elastic thin square plates.
Bull. Calcutta Math. Soc. **55** (1963), 1–10.

Author's summary: "A solution for flexural vibrations of isotropic elastic plates under conditions which are more general than those of the Timoshenko theory given by the author himself is worked out. Here we include the effects of rotatory inertia and shear but do not assume that the displacements are according to a linear law as was assumed by Timoshenko in his one-dimensional theory of bars. Numerical solution for the case of a simply supported thin square plate for various ratios of thickness to the side are obtained and compared with Mindlin's result for the same plate."

Koltunov, M. A. 6697
On the analysis of flexible shallow orthotropic shells with linear heredity. (Russian. English summary)
Vestnik Moskov. Univ. Ser. I Mat. Meh. **1964**, *no.* 5, 79–88.

Author's summary: "The equations are developed and a method is proposed for solving problems dealing with flexible shallow orthotropic shells whose material possesses linear heredity."

La Tegola, Antonio 6698
Premesse alla teoria non lineare per le volte a doppia curvatura di forma qualsiasi. (English summary)
Rend. Accad. Sci. Fis. Mat. Napoli (4) **30** (1963), 181–215.

Concerning the shells of double curvature and referring to the lines of principal curvature, the author deals with the calculus of the strain components and of the first and second order changes of curvature and twist in terms of the displacements of the shell's middle surface. Results are particularized for cylindrical shells and for plane plates. Relations to other results in this direction are discussed. *P. P. Teodorescu* (Bucharest)

Roth, Robert S.; Klosner, Jerome M. 6699
Nonlinear response of cylindrical shells subjected to dynamic axial loads.
AIAA J. **2** (1964), 1788–1794.

This is primarily an extension, to include dynamic effects when the loading is applied suddenly, of the 1950 Donnell and Wan [J. Appl. Mech. 17 (1950), 73–83] static study of the buckling of thin elastic cylinders with imperfections under uniform axial compression. Only radial inertia effects are considered. The initial imperfection is assumed to be a sinusoidal radial deviation with an amplitude of 1, 0.5, 0.1 or 0 times the thickness, and wave lengths the same as the primary term of the buckling deflection. The dynamic critical loading is taken as that at which there is a sudden large increase in the first maximum value, with time, of the amplitude of this primary term. The buckling deflection has four terms like those originated by von Kármán and Tsien [J. Aeronaut. Sci. 8 (1941), 303–312; MR 4, 63] but with time-dependent coefficients, the wave lengths being constant with time and chosen to minimize the critical loading.

The dynamic critical loading is found to have the classical static value for zero initial imperfection and to decrease with increasing imperfections, much as in the 1950 static study. Initial radial velocities, rather than displacements, are found to produce similar effects, but the magnitude of them needed to produce an appreciable effect

leads the authors to conclude that initial imperfections play the dominant role in practical cases. The dynamic critical loading is found to reach a minimum for a duration of loading of $60R(E/\rho)^{-1/2}$, where R is the radius, E is the Young's modulus and ρ is the mass density of the material. Removal of the load before this time progressively increases the critical loading.

Suvernev, V. G. 6700

Small eigen-vibrations of three-layer shells of revolution. (Russian)

Izv. Sibirsk. Otd. Akad. Nauk SSSR Ser. Tehn. Nauk **1964**, *no.* 2, 93–98.

This paper is a generalisation for thick shells of results obtained previously for elastic thin shells by Grigoljuk and Čulkov [Dokl. Akad. Nauk SSSR **150** (1963), 1012–1014]. In the present work each layer is assumed to be transversely isotropic. The special cases of cylindrical and spherical shells are discussed, and the frequencies of vibration corresponding to various values of the geometric and elastic parameters are displayed graphically.

J. Hubert Wilkinson (Battersea)

Nowacki, Witold 6701

★Dynamics of elastic systems.

Translated from the Polish by Henryk Zorski.

John Wiley & Sons, Inc., New York, 1963. 396 *pp.* $15.75.

The aim of this book, which the reviewer believes to have been achieved, is to present "a wide class of dynamics problems occurring in Civil Engineering" in a form suitable for "designers . . . and students, as an auxiliary book in the Theory of Structures". A unified approach to the subject is made in which the dynamics of bar structures forms a link between the vibrations of strings and beams and the vibrations of plates and shells. Problems of wave propagation are discussed in detail, and thermoelastic effects are considered in some problems. Since anelastic effects are of increasing importance in practical analysis, consideration has also been given to materials whose mechanical behaviour is linearly viscoelastic.

The main mathematical tool, which is used throughout the book, is the method of integral transforms. An introduction to Operational Calculus is given in Chapter 13, and fifteen pages of Tables of relevant integral transforms are given in Chapter 14. The mathematical knowledge required of the reader is not beyond that normally taught to undergraduate engineering students.

Chapter 1 is a very readable introduction to the linear theory of elasticity (and thermoelasticity) in which are presented the main concepts: stress and deformation tensors, principal axes, invariants; equations of motion in rectangular and curvilinear coordinates and in terms of displacements; work, energy and uniqueness theorems. A very adequate introduction to linear viscoelasticity is given in Chapter 2. The reviewer regrets that no mention is made of direct numerical solutions of the viscoelastic equations using experimentally determined creep (or other material) functions. Although simple spring-and-dashpot models are useful in giving a qualitative picture of viscoelastic behaviour, their introduction into a numerical solution may be an unnecessary complication.

The remainder of the book is devoted to solutions of particular dynamical problems. Vibrations of strings are treated in Chapter 3, and Chapters 4–6 deal, respectively, with longitudinal, torsional, and transverse vibrations of rods. Free and forced vibrations of continuous beams and of frame structures are considered in Chapters 7 and 8. Chapters 9 and 10 deal with transverse vibrations of plates and shells.

The basic equations of elastic wave propagation are given in Chapter 11, together with the solutions of Rayleigh, Lamb and Pochhammer, the solutions of other elastic wave problems, and the theory of thermoelastic and viscoelastic waves. Chapter 12 deals with approximate methods of analysis for structures.

In summary, the book achieves its main aims, although a set of unworked problems would have increased its worth as a teaching text. It is a worthwhile addition to the existing literature in its field.

F. J. Lockett (Teddington)

Sensenig, Chester B. 6702

Instability of thick elastic solids.

Comm. Pure Appl. Math. 17 (1964), 451–491.

The author investigates stability of equilibrium of several homogeneous isotropic compressible elastic solids using a special form of strain energy function. A non-linear three-dimensional theory of elasticity, equivalent to the theory of small deformations superposed on a large deformation, is used, with no restrictive assumptions concerning the thickness of the bodies. Values of the parameter (critical strain, critical pressure, etc.) are found at which families of buckled solutions branch off from the family of exact simple solutions of the non-linear theory, together with the corresponding modes of buckling.

The thermal buckling of a thin plate in the form of a minimal surface. (Polish and Russian summaries)

Arch. Mech. Stos. **16** (1964), 81–92.

By considering the case of very thin plates, the bending stresses are neglected and the problem of thermal buckling reduces to the determination of a surface. Since the bending stresses are neglected, the plate buckles for any non-linear temperature distribution in the plate's middle surface.

This paper considers surfaces (minimal surfaces) whose mean curvature is zero everywhere, and the corresponding temperature to cause this surface to buckle. A procedure is given by which it is possible to determine from a specified temperature field if such a minimal surface results.

A solution is given for a plate which is heated along one edge, and an experimental verification of the theory is included. The agreement of the analytical predictions and measured values of displacements is encouraging.

Čerenkov radiation in a perfect elastic conductor in a magnetic field of anisotropic action, excited by a moving impulse. (Polish and Russian summaries)

Proc. Vibration Problems **4** (1963), 301–315.

In these two papers the author is interested in information about discontinuity surfaces for elastic media in the state described by the titles. In the linearized theory as applied to an unstressed solid, the steady motion of a point source of energy will result in the presence of Mach cones for dilatation waves if the source velocity V is in the range $V^2>(\lambda+2r)/\rho$ and for both shear and dilatation waves if the velocity is in the range $(\lambda+2\mu)/\rho>V^2>\mu/\rho$. When electromagnetic effects are included in the linearization, the resulting equations indicate the possibility of three types of discontinuity surface, two of them are essentially modifications of the purely elastic Mach cones, and the third is a modification of the Čerenkov cone, set up when a charge moves with sufficiently high speed through a material. The author is interested in finding the degree of coupling between the various effects; in the first paper there is an external magnetic field directed normally to the plane of motion, and in the second it is directed parallel to the plane of motion.

Thermal stresses in a viscoelastic cylinder with temperature dependent properties.

AIAA J. **2** (1964), 1642–1644.

An approximate method of solution is proposed for the transient thermal stress problem of a hollow circular cylinder composed of thermo-rheologically simple viscoelastic material. The approximation consists of employing a constant Poisson's ratio instead of the time-dependent Poisson's ratio (which is a consequence of viscoelastic response in shear and elastic response in dilatation) based on the fact that the deviation of the time-dependent Poisson's ratio from its mean value is small in comparison with the sum of the mean value and unity.

Surfaces caractéristiques des équations de l'équilibre plastique pour un milieu rigide-parfaitement plastique.

J. Mécanique **2** (1963), 313–340.

For a rigid, perfectly plastic material the authors study the characteristic surfaces for three-dimensional stress distributions. It is shown that when the plastic potential is strongly convex, real characteristic surfaces exist only when the deformation is plane. A proof is given that for a material that satisfies Mohr's criterion, real characteristic surfaces exist even for non-plane deformation. A systematic study of this last case is made and applied to problems of symmetry of revolution.

Transformation relative aux solutions des équations du mouvement d'un fluide.

C. R. Acad. Sci. Paris **259** (1964), 1295–1298.

Let $\mathbf{v}(x_i, t)$, $p(x_i, t)$ be the velocity and pressure fields arising from a solution of the Navier-Stokes equations. If a rigid body transformation, relative to fixed axes Ox_i, is applied to the system consisting of the fluid and the axes Ox_i, then the velocity field relative to the fixed axes is not in general a solution of the Navier-Stokes equations. For it to be a solution, $\mathbf{v}$ has to satisfy a further equation involving the instantaneous rotation vector for the axes Ox_i. If this equation is satisfied then, by this transformation process, it is possible to derive from $\mathbf{v}$ further solutions of the Navier-Stokes equations. An application to the motion of a solid in a fluid is given.

Conical flows of an ideal incompressible fluid. (Russian. English summary)

Vestnik Leningrad. Univ. Ser. Mat. Meh. Astronom. **19** (1964), *no.* 2, 107–115.

Solutions are found for the incompressible potential flow of a fluid past a rigid half-cone. At large distances from the axis of the cone the flow behaves like a uniform stream, in planes perpendicular to the axis, plus a non-zero axial component. If the cone is slender (i.e., small included angle), the axial component vanishes. In addition, there is a brief discussion of the flow past a cone, the two halves of which include different angles, and of the class of flows which are independent of the radial distance from the vertex.

Uldrick, J. P.; Siekmann, J. 6719

On the swimming of a flexible plate of arbitrary finite thickness.

J. Fluid Mech. **20** (1964), 1–33.

The swimming of sea animals as simulated by an infinitely thin two-dimensional waving plate is treated by developing a complex velocity potential method and taking into account the thickness of the animal. The measure of the thickness enters through the conformal mapping function which transforms the profile of the fish onto the unit circle. For the basic configuration the symmetric Joukowski profile is employed to represent the profile of the fish. The thrust is assumed to be generated by displacements forming a train of travelling waves of small amplitude which pass down the body of the fish, and the envelope of these waves varies arbitrarily along the length of the fish. The amplitude of these displacement waves is taken as a harmonic function of time. The unsteady boundary conditions are satisfied by introducing a source distribution on the circle, and the problem is linearized by assuming a small unsteady perturbation theory. The velocity induced by the source distribution possesses a singularity in the physical plane, and this is removed by introducing a fluctuating vortex distribution along the wake streamline of the steady base flow in such a way that the induced velocities of the source and vortex distributions combined vanish at the wall. From the base, source and vortex potentials the pressure is calculated from Bernoulli's equation. Numerical results are given from which the authors make the following observations: (1) The thickness of two-dimensional fish tends to reduce the available thrust generated by the swimming motion; (2) The

thickness effect is more pronounced at higher reduced frequencies than at smaller ones; (3) The argument of the Theodorsen function is increased by an amount depending upon the thickness of the fish (this results from the slowing-up effect of fluid particles in the wake); (4) The present theory yields identical results for the lift-moment and thrust with existing thin-plate theories when the thickness parameter vanishes.

The initial-value problem for long waves of finite amplitude.

J. Fluid Mech. **20** (1964), 161–170.

From the author's summary: "A set of four partial differential equations that govern the propagation of an arbitrary, long wave disturbance of small but finite amplitude are derived. The equations reduce to that of Boussinesq when the assumption is made that the disturbance is propagating in one direction only. The equations are hyperbolic with characteristic curves of constant slope. The initial-value problem can be solved very rapidly by numerical integration along characteristics. Some examples are given."

D. G. Hurley (Nedlands)

Rubatta, Antonello 6723

L'onda cilindrica generata da un battente piano.

Atti Accad. Sci. Ist. Bologna Cl. Sci. Fis. Rend. (11) **10** (1962/63), *no.* 1, 103–118.

The author considers the gravity waves generated by a plane wave-maker at one end of a tank of rectangular cross-section of depth h and whose motion is described by

$$x=f(y,t)=(E_1+F_1y/h)\sin kt+(E_2'+F_2'y/h)\sin 2kt+(E_2''+F_2''y/h)\cos 2kt.$$

The tank extends to infinity and no incoming waves are allowed. The author formulates the problem for an inviscid fluid, proposes solving it approximately by a perturbation series and writes out the conditions to be satisfied by the first two terms. He then assumes irrotationality and solves explicitly through the second order. The asymptotic form of the surface is given by

$$\begin{aligned} y=\eta(x,t) &= h+(E_1+F_1)A_0\cos(kt-m_0x) \\ &+(E_1+F_1)^2A_0^2\frac{m_0^2g}{4k^2}\left(\frac{3m_0^2g^2}{k^4}-1\right)\cos 2(kt-m_0(k)x) \\ &+\{(E_1+F_1)^2B_0'+(E_2'+F_2')A_0'\}\cos(2kt-m_0(2k)x) \\ &+\{(E_1+F_1)^2B_0''-(E_2''+F_2'')A_0''\}\sin(2kt-m_0(2k)x), \end{aligned}$$

where $m_0(k)$ is defined by $k^2=m_0g\tanh m_0h$. Graphs are given which allow computation of A_0, A_0', A_0'', B_0', B_0'' as functions of appropriate parameters. The author calls attention to the fact that the part of the velocity potential associated with the last two terms above contributes a mass transport just cancelling the mass transport known to be associated with the third term. It is this which seems to distinguish the present treatment of the problem from a much more thorough one of Fontanet [Houille Blanche **16** (1961), 3–31; ibid. **16** (1961), 174–197; MR **22** #B107], who imposes a vorticity distribution which just cancels mass transport locally.

Bhatnagar, P. L. 6724

Superposability and harmonic analysis of a viscous liquid in the presence of magnetic fields.

Calcutta Math. Soc. Golden Jubilee Commemoration Vol. (1958/59), *Part I, pp.* 205–216. *Calcutta Math. Soc., Calcutta,* 1963.

Incompressible magnetohydrodynamic flows with constant viscosity ν and finite, constant electrical conductivity σ are introduced in the first section of this paper. The two remaining sections, which are totally independent of one another, discuss, respectively, the superposability and the harmonic analysis of such flows, generalizing the purely hydrodynamic results of Ballabh [Proc. Banaras Math. Soc. (N.S.) **2** (1940), 69–79; MR **3**, 283] in the first case and of Kampé de Fériet [Quart. Appl. Math. **6** (1948), 1–13; MR **9**, 631] in the second.

Two flows of the same fluid are called superposable if there exists a third flow of this fluid whose velocity vector V, magnetic field vector $H=\mu^{-1}B$, and (scalar) potential Ω of external forces are each equal to the sum of the corresponding quantities for the two original flows. The following pair of vector equations is found to be necessary and sufficient for the flows indicated by the subscripts 1 and 2 to be superposable:

$$\operatorname{curl}[V_1\times B_2+V_2\times B_1]=0,$$

$$\operatorname{curl}[V_1\times\bar\omega_2+V_2\times\bar\omega_1+(4\pi\rho)^{-1}\{(H_1\cdot\nabla)B_2+(H_2\cdot\nabla)B_1\}]=0.$$

Here ρ denotes the fluid density and $\bar\omega$ the vorticity. Three special cases, involving flows which are irrotational and/or free from magnetic field, are discussed in detail.

The section on harmonic analysis is much less fruitful, being confined mostly to straightforward Fourier transformations of the flow equations and derivation of the

spectral function $\gamma(\bar{k}, t)$ for the kinetic energy (K.E.). The inequality

$$\gamma(\bar{k}, t) \leq (\tau/8\pi^3)\,(\mathrm{K.E.})$$

is obtained; τ denotes the total volume of the flow region. The special case of a flow filling all of space is treated separately; the author writes down the transform equations and suggests an iterative procedure by which they may possibly be solved.

Bretherton, F. P. 6725

Inertial effects on clusters of spheres falling in a viscous fluid.

J. Fluid Mech. **20** (1964), 401–410.

Author's summary: "A compact cluster of 3 to 6 rigid equal spheres is falling under gravity in a viscous liquid. The small effects of inertia on a horizontal regular polygonal configuration are that the polygon expands as it falls and small perturbations from this configuration die out, although when the polygon is large enough it becomes weakly unstable. This is an extension of the analysis of Hocking [same J. **20** (1964), 129–139] which was applied to the experiments of Jayaweera, Mason and Slack [ibid. **20** (1964), 121–128]."

Childress, Stephen 6726

The slow motion of a sphere in a rotating, viscous fluid.

J. Fluid Mech. **20** (1964), 305–314.

From the author's summary: "The uniform, slow motion of a sphere in a viscous fluid is examined in the case where the undisturbed fluid rotates with constant angular velocity Ω and the axis of rotation is taken to coincide with the line of motion. The various modifications of the classical problem for small Reynolds numbers are discussed. The main analytical result is a correction to Stokes's drag formula, valid for small values of the Reynolds number and Taylor number and tending to the classical Oseen correction as the last parameter tends to zero. The rotation of a free sphere relative to the fluid at infinity is also deduced."

Reviewer's additional comments: The alteration of the flow field in the wake due to the Coriolis force is discussed. An interesting feature of the analysis is the use of a three-dimensional Fourier transform to find a solution of Oseen's equation (with a Coriolis term included) when there is a concentrated force located at the origin.

Saffman, Philip G. 6730

The displacement of a viscous fluid from a porous medium.

Proc. 1963 *Heat Transfer and Fluid Mech. Inst.* (*Calif. Inst. Tech., Pasadena, Calif.*, 1963), pp. 176–182. *Stanford Univ. Press, Stanford, Calif.*, 1963.

The paper deals with the flow through a porous medium when a fraction of the fluid being displaced is left behind but is not immobile. If this fraction is constant, the interface moves as if it separated two fluids of modified viscosity, density and interfacial tension, one of which completely expels the other. Assuming that when the macroscopic interface advances the fluid is left behind by trapping and deposition, the author calculates the way the fraction depends on the velocity of the interface according to the model of a porous medium as a random network of capillaries. At the end it is shown that the slower the motion, the smaller is the amount of fluid left behind.

Şt. I. Gheorghiţă (Bucharest)

Sparrow, E. M.; Lin, S. H.; Lundgren, T. S. 6731

Flow development in the hydrodynamic entrance region of tubes and ducts.

Phys. Fluids **7** (1964), 338–347.

A new method has been devised for determining the developing incompressible laminar flow and corresponding pressure drop in the entrance region of tubes and ducts. In a cylindrical duct parallel to the x-axis the x-momentum equation

$$\mathbf{v}\cdot\nabla u = -\partial(p\rho^{-1})/\partial x + \nu\nabla^2 u \tag{1}$$

is simplified by standard assumptions that $p=p(x)$ and $\partial^2u/\partial x^2$ is negligible relative to $\nabla^2 u$ and the novel linearization $\mathbf{v}\cdot\nabla u=s(x)U\partial u/\partial x$, where U is the constant mean velocity and $s(x)$ remains to be determined. With these simplifications and other minor manipulation, (1) yields

$$(2)\qquad U\partial u/\partial x^* + \nu A^{-1}\oint_C (\partial u/\partial n)ds = \nu\nabla_1{}^2 u,$$

where A is the cross-sectional area of the tube, C its boundary, $dx=s(x)dx^*$, and $\nabla_1{}^2=\partial^2/\partial y^2+\partial^2/\partial z^2$. The desired solution of (2) is expressed as

$$u = u_{fd}+u^*,$$

where u_{fd} is the fully-developed axial velocity. The correction u^* is expanded in an eigenfunction series of product solutions $e^{-\alpha_i{}^2x^*}g_i(y,z)$ of (2). The function $s(x)$ is determined by insisting that $\partial p/\partial x$ shall have the same value (despite all of the preceding simplifications) when determined by both momentum and mechanical energy considerations. Extensive computations and comparisons with results of earlier investigators have been made for circular tubes and parallel plate channels.

Ermak, Ju. N.; Neiland, V. Ja. 6733

On the theory of the three-dimensional laminar boundary layer. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 950–954.

First the authors indicate the difficulties of the three-dimensional boundary layer theory. Then by using $ds^2=dh_1{}^2dx^2+dh_2{}^2dy^2+dz^2$ and $H=c_pT+\frac{1}{2}(u^2+v^2)$ and writing the equations for u, v, p and H, they obtain in a certain case a generalization of Crocco's integral in the form $H=Au+Bv+C$ (A, B and C constants). At the end they consider cases when the three-dimensional problem reduces to the two- or one-dimensional problem.

St. I. Gheorghiţă (Bucharest)

Fife, Paul 6734

A note on exterior Dirichlet problems and an application to boundary layer theory.

J. Differential Equations **1** (1965), 95–113.

The motivating interest of this paper lies in the following problem: Given a simple closed curve Γ in the (x,y)-plane, to find a solution of the Prandtl (boundary-layer) equations corresponding to prescribed tangential velocity $w(\tau)$ on Γ and suitably matched with a potential flow defined in the exterior e of Γ and vanishing at infinity. The matching is accomplished by means of the pressure $p(\tau)$ arising from the (multivalued) potential solution $\varphi(x,y)$ of the exterior Neumann problem, with the condition $\nabla\varphi\to 0$ at infinity. This solution contains an arbitrary multiplicative constant μ, which then appears in the boundary-layer equation. The author shows that under certain restrictions on $w(\tau)$ and on Γ, this simultaneous problem admits to first-order approximation a solution pair $[w,\mu]$ such that $w(\tau)$ is periodic with period equal to the circumference of Γ. The author remarks that a general theorem on existence of periodic solutions of parabolic equations could be obtained by the same method.

{The interpretation of the author's result in terms of the strict theory of the Navier-Stokes equations is not clear. The author seems to have the impression that the existence of strict solutions has been proved. However, the known existence theorems—including those to which the author refers—apply only to flows in dimension $n=3$. The case $n=2$ is, in the reviewer's opinion, one of the basic open questions of the theory. Nevertheless, the reviewer had arrived independently at the view that a problem similar to the one studied in this paper should be accessible from the standpoint of finding a strict solution of the hydrodynamical equations. It remains to be seen how these ideas will develop, and in what ways the results will relate to those of the author.} *R. Finn* (Stanford, Calif.)

The heat transfer from a rotating disk.

Quart. J. Mech. Appl. Math. **17** (1964), 331–349.

Author's summary: "The heat transfer from a rotating disk maintained at a constant temperature is considered for large and small values of the Prandtl number. On the assumption that there is a linear relationship between the viscosity and the temperature the momentum equations are reduced to their incompressible form, and attention is then concentrated upon the energy equation. The effects of wall heating and heating due to viscous dissipation are considered separately, and the heat transfer is expressed as a series in terms of the Prandtl number for both large and small Prandtl numbers."

Upon reading the paper it is found that this summary is precise and that the paper is an interesting and scholarly one citing several related and pertinent references. Comparisons between asymptotic and exact solutions are given as a function of fluid Prandtl number and once again the usefulness and validity of asymptotic solutions to the boundary layer equations are illustrated.

W. H. Dorrance (Ann Arbor, Mich.)

Selig, F. 6737

Variational principle for Rayleigh-Taylor instability.

Phys. Fluids 7 (1964), 1114–1116.

In this paper, the author presents a new variational formulation for the stability problem of superposed fluids.

An eigenvalue problem is formulated by the usual technique of analyzing the disturbance into normal modes. By grouping the terms in a slightly different way from what was done previously by other authors, the author obtains the following formula:

$$-n_i \int_L \rho\left[w_i w_j + \frac{1}{k^2}(Dw_i)(Dw_j)\right] dz + \frac{g}{n_i}\int_L (D\rho) w_i w_j \, dz =$$

$$\int_L \frac{\mu}{k^2}\{[(D^2+k^2)w_i][(D^2+k^2)w_j] + 4k^2(Dw_i)(Dw_j)\}\, dz.$$

This formula enables the author to establish that overstability cannot occur (without the restriction $D^2\mu > 0$).

The variational formulation of the problem is then obtained by putting $i = j$ in the above formula. The author also shows that the variational principle expresses an energy balance. *W. Lai* (Troy, N.Y.)

Sparrow, E. M.; Munro, W. D.; Jonsson, V. K. 6738

Instability of the flow between rotating cylinders: The wide-gap problem.

J. Fluid Mech. 20 (1964), 35–46.

Consideration is given to cylinders rotating in the same direction and in opposite directions, with radius ratios ranging from 0.95 to 0.1. The stability problem is solved by a method based on direct numerical integration of the differential equation for the disturbance amplitude function. Detailed numerical results are presented for the critical Taylor numbers and wave-numbers. These results are used to determine the range of applicability of the closed-form predictions of Taylor [Philos. Trans. Roy. Soc. London Ser. A **223** (1923), 289–343] and Meksyn [*New methods in laminar boundary-layer theory*, Pergamon, New York, 1961], which were derived for narrow-gap conditions. *D. W. Dunn* (Ottawa, Ont.)

Sastry, U. A. 6739

Heat transfer by laminar forced convection in a pipe of curvilinear polygonal section.

J. Sci. Engrg. Res. 7 (1963), 281–292.

The author treats the steady, fully developed laminar flow in a pipe of polygonal cross-section using a complex variable method developed by N. I. Muskhelishvili [*Some basic problems of the mathematical theory of elasticity*, Noordhoff, Groningen, 1963]. The cases worked out in detail include the heat transfer in a pipe of hexagonal cross-section. *L. J. Crane* (Dublin)

Stuart, J. T. 6740

On the cellular patterns in thermal convection.

J. Fluid Mech. 18 (1964), 481–498.

A detailed examination is made of the problem of describing what is actually observed in a thermal convection experiment. The existing rough classification of the cellular patterns on the basis only of their periodicity is sharpened by the introduction of further criteria for deciding which streamlines are singled out by the eye (or camera). Since no one has ever seen a thermal convection cell of infinitesimal amplitude, it seems appropriate that features of known approximations for the finite-amplitude motions are employed. The author points out that his criteria indicate that we may "see" cells of hexagonal outline but not of square or rectangular outline. The distinction between the hexagonal case and the others appears to rest upon the existence of a certain positive definite feature of the linearized solutions for the former, corresponding examples of which are merely non-negative definite in the latter. This appears to be a rather fine point in the scheme of the complicated and approximate theory of finite-amplitude convection. Furthermore, in advocating his argument for the result that hexagonal cells enjoy a preferred status insofar as mere visibility is concerned, the author has forgotten to convince us of the result; we wish he had included some photographs or some further experimental evidence to show that Rayleigh's square cell is not a possible convection cell. *F. E. Bisshopp* (Providence, R.I.)

Butler, Terence 6741

A mathematical example by Hopf with features of turbulence.

J. Math. Anal. Appl. 9 (1964), 215–233.

L'auteur considère l'équation fonctionnelle suivante:

$$(1) \qquad w_t = T(w) - L(w) + \mu w_{xx}, \qquad \mu > 0,$$

où

$$T(w) = -\frac{\pi^2}{4}\int_0^{2\pi}\int_0^{2\pi} w(y)w(y')\bar{w}(y+y'-x)\,dy\,dy',$$

et $L(w) = F * w$ est la convolution de w par une distribution F définie sur $(0, 2\pi)$, et dont les coefficients de Fourier sont $o(n^2)$. $w = u + iv$ est une inconnue complexe, fonction de x, t. u et v jouent le rôle des composantes de la vitesse dans un écoulement visqueux bidimensionnel. L'équation (1) est un modèle des équations de l'hydrodynamique, qui comporte les principales particularités des équations véritables, mais qui est plus accessible. Si $F = \sum (a_n - ib_n)e^{inx}$, la fonction

$$W(x, t) = \sum (a_n - n^2\mu)^{1/2} \exp i(nx + \psi_n), \qquad \psi_n = b_n t + c_n,$$

où la somme est étendue aux N valeurs de n pour lesquelles $a_n > n^2\mu$, est solution de (1) quels que soient les c_n. On peut associer à toute solution $w(x, t)$ (dont les coefficients de Fourier ne sont pas tous nuls pour $t = 0$) une fonction $W(x, t)$ telle que $w - W$ et $w_x - W_x$ tendent vers 0 lorsque $t \to \infty$, uniformément en x.

Soit $\mathscr{F}$ une fonctionnelle continue dans l'espace $-w$, normé par $\|w\|_1 = \sup_x |w(x)| + \sup_x |w_x(x)|$, des fonctions périodiques en x ayant deux dérivées continues. Si les b_n sont linéairement indépendants sur les entiers, on a

$$\bar{\mathscr{F}} = \lim_{T\to\infty} \frac{1}{T}\int_0^T \mathscr{F}(W(t))\,dt$$

$$= \int_0^{2\pi} \cdots \int_0^{2\pi} f(\psi_{n_1}, \psi_{n_2}, \cdots, \psi_{n_N}) \prod \frac{d\psi_{n_i}}{2\pi},$$

où f représente $\mathscr{F}(W(t))$, considéré comme fonction de $\psi_{n_1}, \cdots, \psi_{n_N}$.

La moyenne temporelle $\bar{\mathscr{F}}$ de la fonctionnelle $\mathscr{F}(W(t))$

se représente ainsi par une moyenne statistique $\int \mathcal{F}\, dP$ étendue à une variété de dimension finie de l'espace $-w$. On va étudier plus particulièrement les moments de la vitesse en k points et leur comportement lorsque $\mu \to 0$.

On peut poser $w = u + iv$, $u = \sum_{a_n > n^2\mu} u_n$, $v = \sum_{a_n > n^2\mu} v_n$, avec

$$u_n = (a_n - n^2\mu)^{1/2} \cos(\psi_n + nx),$$

$$v_n = (a_n - n^2\mu)^{1/2} \sin(\psi_n + nx).$$

Ensuite, on considère dans R_{2k} le vecteur $\{u(x_1), v(x_1), \cdots, u(x_k), v(x_k)\}$ qui est une somme de vecteurs indépendants dont le nombre augmente indéfiniment quand $\mu \to 0$.

On associe au vecteur $\{u_n(x_1), v_n(x_1), \cdots, u_n(x_k), v_n(x_k)\}$ sa projection normée $X_n(\mu)$ sur un vecteur arbitraire $\{\lambda_1, \cdots, \lambda_{2k}\}$. Les $X_n(\mu)$ sont des variables aléatoires indépendantes, et on exprime la variance de leur somme. On en déduit une condition pour que la somme $\sum X_n(\mu)$ ait, quand $\mu \to 0$, une distribution limite normale, puis une condition pour qu'il en soit de même de la loi de probabilité jointe des $2k$ variables aléatoires $u(x_1), v(x_1), \cdots, u(x_k), v(x_k)$ (préalablement normées). La condition essentielle est que

$$\lim_{\mu \to 0} \left[\max_{a_n > n^2\mu} \frac{a_n - n^2\mu}{\sum \frac{1}{2}(a_n - n^2\mu)} \right] = 0.$$

Elle est liée aux propriétés de la distribution F. On indique un procédé de construction des a_n qui satisfait à la condition ci-dessus.

Si les points x_i sont fixes, les coefficients de corrélation entre les u ou les v en deux points distincts tendent vers 0 avec μ, et l'on peut trouver des suites a_n pour lesquelles ce résultat reste vrai, même si les x_i dépendent de μ, à condition que $x_i - x_j$ appartienne à un intervalle fermé intérieur à $(0, 2\pi)$. On peut au contraire chercher des conditions pour que ces coefficients de corrélation soient indépendants de μ. On définit des suites a_n pour lesquelles il en est ainsi, à condition que les points x_i varient en fonction de μ (ou du nombre N), de telle sorte que les $N(x_i - x_j)$ soient asymptotiquement constants: cela a lieu par exemple si $a_n = n^s$ $(s < 2)$ pour $n > 0$, et $a_n \leq 0$ pour $n \leq 0$. Si $N(x_i - x_j) \to \beta$, on trouve dans ce cas que les coefficients de corrélation de question sont à la limite de la forme $\cos t\beta$, $0 < t < 1$.

Deardorff, J. W. 6742

A numerical study of two-dimensional parallel-plate convection.

J. Atmospheric Sci. **21** (1964), 419–438.

The Boussinesq equations for two-dimensional convection between horizontal plates are integrated numerically for Rayleigh number 6.75×10^5 and Prandtl number 0.71. The numerical method uses a grid in physical space and finite-difference equations which preserve exactly a restricted form of energy conservation. The results for the total heat transport agree qualitatively with experiment but are quantitatively too large. Sharp boundary-layering occurs, but there is no breakdown into small turbulent eddies. This is ascribed (correctly, in the reviewer's opinion) to the assumption of two-dimensional motion. Detailed graphical results are presented for the flow and temperature fields resulting from several initial conditions.

Kraichnan, Robert H. 6744

Approximations for steady-state isotropic turbulence.

Phys. Fluids 7 (1964), 1163–1168.

The direct interaction hypothesis for stationary, isotropic turbulence is formulated in the wave-number, frequency domain, rather than in the wave-number, time domain, used previously. The resulting equations are simpler, but less complete in their specification of the statistical properties of the turbulence, than in the original formulation. They involve the wave-number energy spectrum, a correlation frequency for each wave-number and the characteristic response frequency for each wave-number. These equations exhibit some similarities with those derived by Edwards [J. Fluid Mech. 18 (1964), 239–273], who used a Fokker-Planck type of approximation; these (and the important differences) are discussed.

O. M. Phillips (Baltimore, Md.)

Kraichnan, Robert H. 6745

Mixed Lagrangian-Eulerian approach to turbulent dispersion.

Phys. Fluids 7 (1964), 1717–1719.

On considère un champ scalaire turbulent $\psi(x, t)$ qui diffuse suivant l'équation

$$(1) \qquad \frac{\partial \psi}{\partial t} = -u \cdot \nabla \psi,$$

où u est un champ de vitesse incompressible. Si $\xi(x, t|s)$ est le déplacement des particules entre les instants s et t, on a

$$\psi(x, t) = \psi[x - \xi(x, t|0), 0]$$
$$= \exp[-\xi(x, t|0) \cdot \nabla]\psi(x, 0).$$

On prend ensuite les moyennes, en supposant ψ et u aléatoires et indépendants et l'on obtient les diverses corrélations spatio-temporelles de ψ. Puis on suppose que la vitesse u^L des particules (au sens de Lagrange) est normalement distribuée. On trouve par exemple

$$\langle \psi(x, t) \rangle = \exp \tfrac{1}{2}\Xi_{ij}(x, t; x, t|0, 0)\nabla_i \nabla_j,$$

où $\Xi_{ij} = \langle \xi_i(x, t|s)\xi_j(x', t'|s') \rangle$ s'obtient par intégration du tenseur de corrélation $U_{ij}^L(x, t, x', t'|r, r')$ du vecteur u^L. Deux expressions approchées de U_{ij}^L sont données et discutées. L'expression des corrélations de ψ, grâce à l'hypothèse de normalité, est calculable. Les exemples de $\psi(x, 0) = \delta^3(x)$ et $\langle \psi(x, 0) \rangle = 0$,

$$\langle \psi(x, 0)\psi(x', 0) \rangle = \cos[k \cdot (x - x')]$$

sont examinés.

Ces méthodes sont étendues à l'équation

$$(\partial/\partial t - k\nabla^2)\psi = u \cdot \nabla \psi + f,$$

qui contient un terme de diffusion moléculaire, et un

terme extérieur f indépendant de u. La diffusion moléculaire est représentée par un champ de vitesse complémentaire homogène, isotrope, stationnaire, dont la longueur et le temps de corrélation sont très courts, et entre comme un terme correctif dans les formules ci-dessus.

Quelques suggestions sont ensuite données sur l'application de ces méthodes aux équations de Navier-Stokes et sur la valeur des hypothèses de normalité.

The relative motion of liquid particles in turbulent flow.

Izv. Akad. Nauk SSSR Ser. Geofiz. **1964**, 426–429 (*Russian*); *translated as Bull.* (*Izv.*) *Acad. Sci. USSR Geophys. Ser.* **1964**, 258–260.

This paper is a continuation of previous work by the author [Ž. Èksper. Teoret. Fiz. **44** (1963), 2159–2168; MR **28** #1846] in which a method for the statistical description of relative particle motion was proposed. In the present work the third moments for relative motion of two particles are calculated, and a method for calculation of higher-order moments for a system of N particles is suggested. Turbulence is assumed to be locally homogeneous and locally isotropic. Only the inertial time interval, during which viscosity effects are assumed negligible, is considered. It is found that the mean cube of the separation distance of the two particles is proportional to the cube of the time for large times.

Remarks on the Malkus theory of turbulent flow. (French summary)

Mécanique de la Turbulence (*Marseille*, 1961), *pp.* 167–180. *Éditions Centre Nat. Recherche Sci., Paris*, 1962.

This paper presents an outline of the Malkus theory of turbulent flow and the experimental evidence supporting the theory. Malkus's concepts are applicable to stationary flows, statistically homogeneous on planes parallel to the bounding surfaces, and are based on four principles: (1) The mean velocity and temperature fields can approach, but never exceed, the condition for marginal stability of an inviscid fluid; (2) There is a smallest scale of motion which contributes to the transport of momentum or of heat; (3) This smallest scale is that scale of motion which is marginally stable on the mean field; (4) The flow satisfies an integral condition, like the maximization of the rate of energy release for a fixed volume of channel flow.

One of the main theoretical interests of the author's discussion, in the case of channel flow, is the distinction—clearly made for the first time—between assertions 1 and 2, on one side, which allow the prediction of the form of the velocity distribution, and 3 and 4, on the other side, which are required to determine the scale. (Using assertions 1 and 2 alone, together with a simple assumption very close to 4, the author actually succeeded in determining the velocity profile qualitatively.) The discussion of the experimental evidence is very thorough and convincing. The Malkus predictions for heat convection are qualitatively in agreement with measurements of mean temperature in the laboratory and in the atmosphere, which is not true of the similarity predictions. For Poiseuille flow, the advantage of the Malkus theory is to provide a numerical prediction which is in very fair agreement with experiments.

In two additional sections, the author discusses the relation of Malkus's concepts to the concepts of the statistical theory and the possibility of describing developing flows by a modified form of the theory.

On the velocity distribution in turbulent shear flow.

Z. Angew. Math. Mech. **43** (1963), 561–563.

The author derives logarithmic velocity distributions for smooth and for fully rough passages with radially varying shear stress. The assumption is made that velocity is a function of the size of the cross-section, the size of the roughness element, kinematic viscosity, friction velocity, and distance from wall. When the passage is fully rough, the kinematic viscosity is assumed to drop out of the functional relation. It appears that the derivation is slightly more general than those given by previous authors.

Schäfer, Wolfgang 6752

Behandlung von Freistrahlproblemen mittels der Hodographenmethode bei quadratischer Approximation der Adiabate. I. Das Ausströmen aus einem gradlinig begrenzten Gefäss.

Wiss. Z. Techn. Hochsch. Chem. Leuna-Merseburg **5** (1963), 47–52.

In a steady non-viscous subsonic compressible flow let $we^{i\theta}$ be the velocity, M the local Mach number, and Ψ the stream function. Let $\log \omega = \int_{w_*}{}^{w} \tau w^{-1} dw$ and $K^2(\omega) = \tau\rho_\infty/\rho$. Then $\psi = K(\omega)\Psi$ satisfies

$$(1) \qquad \psi_{\omega\omega} + \omega^{-1}\psi_\omega + \omega^{-2}\psi_{\theta\theta} + F(\omega)\psi = 0,$$

where $-KF = d^2K/d\omega^2 + \omega^{-1}dK/d\omega$. The author makes the approximation $2F = k^2\omega^{2m}$, where k and m are constants. Note that $k = M = 0$ corresponds to incompressible flow; $k = 0$, $M \neq 0$ to the von Kármán-Tsien equation of state. The case $m = 0$, which corresponds to a second-order approximation to $p/p_\infty = (\rho/\rho_\infty)^\gamma$, is of interest for comparison with theoretical and numerical results of other authors mentioned in the paper. For general m the author constructs solutions of (1) by Bergman's integral operator method which reduce in the limit $k = M = 0$ to stream functions of incompressible flows. The process is carried out in detail for efflux of a symmetrical jet from an infinite reservoir with straight walls, for which the incompressible stream function is known. *J. H. Giese* (Aberdeen, Md.)

On the solution of Chaplygin's equation for transonic flows with a local supersonic zone terminated by a shock wave. (Russian)

Izv. Vysš. Učebn. Zaved. Matematika **1963**, no. 4 (35), 56–60.

F. I. Frankl' [Prikl. Mat. Meh. **19** (1955), 385–392; MR **17**, 550] has constructed an example of a flow with a locally supersonic region terminated by a straight shock. The author has attempted to generalize this result by expanding the stream-function in a series of the form

$$\psi = \sum_{k=0}^{\infty} \rho^{(2k+8)/3} S_k(t),$$

where the term for $k = 0$ corresponds to the example of Frankl', and ρ and t are functions of the magnitude and inclination of the flow velocity. In fact, $\rho = \text{const}$ are characteristics in the supersonic region. The author shows that the required function S_2 does not exist. In an addendum Frankl' has proposed an alternative expansion for ψ. *J. H. Giese* (Aberdeen, Md.)

On curved shock wave in three-dimensional conducting gas flows.

Proc. Nat. Inst. Sci. India Part A **29** (1964), 7–17.

Author's summary: "The first and the second derivatives of the density, the pressure, the velocity and the magnetic field vector behind the shock, in the case of steady flow of conducting gases in the absence of viscosity and heat conduction, have been determined. Consequently, the curvatures and torsions of the streamlines and the magnetic lines of force, the current density and the vorticity behind the shock have been found."

Ericksen, J. L. 6761

Nilpotent energies in liquid crystal theory.

Arch. Rational Mech. Anal. **10** (1962), 189–196.

Hydrostatic theories are discussed, in which the free energy is a function of a vector **n** and its gradients. The form of the free energy affects the forms of the equations and boundary conditions satisfied by **n**. One of the material constants in the Oseen-Frank expression for the free energy drops out of the differential equations. Consequently, experiments to determine this constant must take the boundary conditions into account. If, as in this case, two different free energy functions yield identical equations for **n**, their difference is called a nilpotent energy. An explicit expression is obtained for the most general form of a nilpotent energy.

On the stability of visco-elastic liquids in heated plane Couette flow.

J. Fluid Mech. **17** (1963), 353–359.

Author's summary: "The stability of thermally stratified plane Couette flow of visco-elastic liquids, with respect to disturbances of small amplitude, is considered. It is found that an initial state of finite elastic stress is necessary for elasticity to effect stability. The critical Rayleigh number of the flow is shown to be decreased for all non-zero rates-of-strain. This greater instability is due solely to the variations of the apparent viscosity with shear rate. In this way, the presence of elasticity can be said to have a destabilizing effect on the flow."

Nonsteady helical flows of second-order fluids.

Phys. Fluids 7 (1964), 833–841.

Authors' summary: "Some exact solutions of the third-order vector partial differential equation describing nonsteady flows of incompressible second-order fluids are presented. Although periodic simple shearing flow is also discussed, the main emphasis here is on helical flows between moving coaxial cylinders, particularly periodic flows of the Couette and Poiseuille type. The calculations suggest that, for such periodic helical flows, measurements of the radial thrusts on the bounding cylindrical walls supply practicable methods for the determination of normal-stress coefficients."

Misra, Shankar Prasad 6767

Elastico-viscous fluid flow past a circular cylinder or a flat plate with suction.

Ganita **14** (1963), 98–103.

The author considers first-order effects of a particular elastico-viscous fluid flowing over (i) a circular cylinder with axisymmetry, and (ii) a flat plate as a limiting case of the cylinder. The problem is examined with suction at the boundaries.

W. O. Criminale, Jr. (Princeton, N.J.)

Pipkin, A. C. 6768

Annular effect in viscoelastic fluids.

Phys. Fluids 7 (1964), 1143–1146.

From the author's summary: "In the oscillating motion of an incompressible viscoelastic fluid in a pipe, at high Reynolds number the root-mean-square axial velocity has its maximum value in a boundary layer at the wall of the tube. The elasticity of the fluid can make this annular effect

much more pronounced than it is in the case of a Newtonian viscous fluid. The analysis is carried out for small-amplitude oscillations of a general viscoelastic fluid, and the exact solution for this case is compared with the solution obtained by the boundary-layer approximation. The solution in the case of slow motion of arbitrary amplitude is also considered, and it is shown that no annular effect occurs in this case." *M. N. L. Narasimhan* (Bombay)

Rintel, L. 6769

Flow of non-Newtonian fluids at small Reynolds number between two discs: One rotating and the other at rest.

Second-order Effects in Elasticity, Plasticity and Fluid Dynamics (*Internat. Sympos., Haifa*, 1962), *pp.* 467–472. *Jerusalem Academic Press, Jerusalem; Pergamon, Oxford*, 1964.

The Reiner effect in air thrust bearings is discussed on the basis of the Reiner-Rivlin constitutive equation. It is concluded that the Reiner-Rivlin equation is not adequate to account for the observed phenomena.

Segawa, Wataru 6770

Rheological equations of viscoelastic liquid.

J. Phys. Soc. Japan **19** (1964), 206–210.

A constitutive equation for stress as a function of strain and strain-rate is applied to fluids by taking the strain to be an undefined quantity. The equation is simplified by postulating that the principal axes of stress and undefined strain coincide. Problems of steady simple shearing motion and flow through pipes are solved by postulating values for the strain. *A. C. Pipkin* (Providence, R.I.)

Srivastava, P. N. 6771

Propagation of small disturbances in a visco-elastic fluid contained in an infinite cylinder due to the slow angular motion of its base.

Indian J. Math. **6** (1964), 29–38.

A special case of Oldroyd's stress-strain-rate relation for a second-order visco-elastic fluid is considered, with the parameters restricted to a single relaxation-time constant λ and kinematic viscosity ν. The author then proceeds to solve the problem of the motion of such a fluid, initially at rest, in a circular cylinder subject to either impulsive or sinusoidal angular motion of the base for $t>0$. Because of the symmetry of the problem, a linear wave equation is obtained for the azimuthal component of velocity. {Reviewer's note: From the linear form of this differential equation, it is clear that the non-linear terms in the stress-strain-rate relation can have no effect on the fluid motion for this problem.} Solutions are obtained by transform techniques in the form of infinite series. The resulting motion exhibits the behavior of an elastic shear wave with propagation velocity $\sqrt{(\lambda/\nu)}$, as should be expected from the form of the differential equation. The author obtains the ordinary viscous fluid results for the limit of zero relaxation time.

O. R. Burggraf (Columbus, Ohio)

Srivastava, A. C. 6772

Torsional oscillations of an infinite plate in second-order fluids.

J. Fluid Mech. **17** (1963), 171–181.

Author's summary: "The flow of an incompressible second-order fluid due to torsional oscillations of an infinite plate when the fluid is infinite in extent, as well as the case when it is bounded by another stationary parallel plate, has been considered by expanding the velocity components and the pressure in powers of the amplitude of oscillation of the plate. In both cases the first-order solution consists of a transverse velocity and the second-order solution gives a radial-axial flow composed of a steady part and a fluctuating part. In the case of the unbounded plate the steady part of the radial flow does not vanish outside the boundary-layer region. Hence the equations are solved by another approximate method for the steady part of the flow. The effects of the non-Newtonian terms are to increase the non-dimensional boundary thickness and the shearing stress on the plate. In the case of two plates the velocity components and the shearing stresses on the plates have been expressed in powers of the Reynolds number R for its small values. Their asymptotic behaviour for large R has also been studied. The asymptotic expansion of the fluctuating part of the radial-axial flow shows that the boundary layer is developed at both the plates." *A. C. Pipkin* (Providence, R.I.)

Ferrero, Giorgio M. 6773

Teoremi di confronto relativi alla pressione e all'energia in magnetofluidodinamica.

Boll. Un. Mat. Ital. (3) **19** (1964), 185–192.

A classical theorem in fluid dynamics [see, e.g., Serrin, *Handbuch der Physik*, Band 8/1, pp. 125–263, esp. p. 261, Springer, Berlin, 1959; MR **21** #6836b] is extended to magnetohydrodynamics as follows: If in a steady, incompressible, and viscous flow $\nu\nabla\cdot(\mathbf{H}\cdot\nabla\mathbf{H})\gtrsim\nabla\cdot(\mathbf{v}\cdot\nabla\mathbf{v})$, the total pressure (including the magnetic contribution) takes its maximum value on the boundary of the flow region. Notice that both terms in the inequality are positive.

Some properties of flows in which $\mathbf{H}\cdot\nabla\mathbf{H}=0$ are then established. *B. Bertotti* (Frascati)

Fucks, W.; Uhlenbusch, J. 6774

Hydromagnetische Lagertheorie. (English and Russian summaries)

Z. Angew. Math. Mech. **43** (1963), 553–560.

Hydromagnetic flow between two flat plates with a small gap and a small inclination between each other is discussed in the presence of a transversal magnetic field perpendicular to the plate. Induced pressure difference due to the Couette motion of one plate is determined. Similar study is made on the flow between cylindrical journal and bearing in the presence of a magnetic field perpendicular to the surface of the journal. The force and moment on the bearing can be reduced for large Hartmann numbers H to forms similar to those in the non-magnetic case except for factors proportional to H.

Gundersen, Roy M. 6775

The effects of heat addition to one-dimensional magneto-hydrodynamic flow. II. (French, German, Italian and Russian summaries)

Internat. J. Engrg. Sci. **2** (1964), 291–304.

Part I appeared in same J. **1** (1963), 359–369 [MR **27**

#5464]. From the author's summary: "The transients due to uniform heat addition to the steady subtransonic, one-dimensional flow of an ideal, inviscid, perfectly conducting compressible fluid, subjected to an oblique magnetic field with two nonzero components, are determined by the use of a linearization based on small heat addition. Both the slow and fast wave cases are studied. Although the solution obtained ceases to be valid in the neighborhood of transonic flow, and this difficulty is due to the inadequacies of the linearization which approximated the characteristics of the base flow by parallel families of lines, a solution valid for all flow speeds may be obtained by making a more detailed examination of the negative characteristics. The solutions obtained include, as special limiting cases, the solutions for the corresponding problems in conventional gas dynamics and when the applied field is transverse." *M. N. L. Narasimhan* (Bombay)

Infeld, E. 6776

Some exact solutions of the equations of magnetohydrodynamics for magnetic plane-symmetrical fields.

Bull. Acad. Polon. Sci. Sér. Sci. Math. Astronom. Phys. **12** (1964), 233–238.

Linearized yet exact solutions having plane symmetry are derived for the equations of magnetohydrodynamics. Several geometries are considered, including the flow in a 2-dimensional quadrupole field. Time-dependent solutions are obtained by Fourier superposition, and the application to boundary-value problems is briefly considered.

J. S. Goldstein (Waltham, Mass.)

Jukes, J. D. 6777

On the Rayleigh-Taylor problem in magnetohydrodynamics with finite resistivity.

J. Fluid Mech. **16** (1963), 177–186.

In an attempt to elucidate how the assumption of infinite conductivity may mask important effects, the author considers a modification of the Rayleigh-Taylor stability problem. This consists of two incompressible, inviscid fluids of different densities in a gravitational field and supported one on the other. The upper fluid is electrically conducting and the system is placed in a uniform, horizontal magnetic field. For waves propagating along field lines, solutions appear which do not occur in the idealized infinite conductivity analysis. Moderately long "stabilized" waves are now found to grow aperiodically at a rate $\alpha\rho^{1/3}$ (ρ is the resistivity). Other modes are found to be periodic and damped at a rate $\alpha\rho^{1/2}$.

S. A. Berger (Berkeley, Calif.)

Kellogg, Paul J. 6778

Solitary waves in cold collisionless plasma.

Phys. Fluids **7** (1964), 1555–1571.

Author's summary: "The propagation of finite amplitude waves in a magnetized plasma, in which thermal motion and collisions are neglected, is studied for arbitrary direction of propagation. Solutions for oblique propagation are presented, which complement the analytical solutions for propagation perpendicular to the magnetic field obtained by Adlam and Allen and others, and for parallel propagation obtained by Saffman. Oblique propagation is much more complicated than the two limiting cases in that (1) In a given direction and at a given speed higher than the Alfvén speed there are a large number of different waves, and (2) As shown by Saffman, there are additional waves whose speed is less than the Alfvén speed. These submagnetic waves are investigated in the limit of infinite mass ratio, and the results are compared with computer calculations. The stability of the waves against the two-stream instability is investigated, and it is shown that (1) The supermagnetic waves (speed higher than Alfvén speed v_A) are destroyed by the two-stream instability unless v_A/c is sufficiently large, and (2) The submagnetic waves are destroyed by the two-stream instability unless the pressure is non-negligible."

Motion of a charged particle in a constant magnetic field and a transverse electromagnetic wave propagating along the field.

Phys. Rev. (2) **135** (1964), A381–A389.

Authors' summary: "The relativistic equation of motion is examined for a charged particle in a constant magnetic field and a transverse electromagnetic wave propagating along the field. A general discussion is given of the effects at cyclotron resonance of the magnetic field of the wave and the relativistic mass increase with energy. An exact solution to the equation of motion is found for the case of a circularly polarized wave. The solution shows that when the index of refraction of the medium in which the wave propagates is not unity, the energy of the particle is a periodic function of time, the exact relationship being expressible in terms of elliptic integrals. When the index of refraction is unity, the effect of the magnetic field of the wave just compensates for the change in mass with energy, and the energy of the particle increases indefinitely at resonance. Several possible applications of this solution to classical cyclotron resonance phenomena are pointed out. As a numerical example, the case of an electron in a constant magnetic field of 1000 G initially at resonance with microwaves whose **E** field is 0.1 esu is considered."

S. A. Berger (Berkeley, Calif.)

Sandler, Stanley I.; Dahler, John S. 6787

Nonstationary diffusion.

Phys. Fluids 7 (1964), 1743–1746.

Authors' summary: "A simple proof is given that the telegrapher's equation provides a more rigorous description of diffusion than does the familiar diffusion equation. Solutions of these two equations are compared and it is shown that they are numerically indistinguishable for most cases of interest. The signal velocity of a concentration pulse is found to be $(p/\rho)^{1/2}$ with p the pressure and ρ the fluid density. It is found that in special circumstances the reflection and/or dispersion of concentration waves can occur."

Barakat, Richard 6788

Theory of the coherency matrix for light of arbitrary spectral bandwidth.

J. Opt. Soc. Amer. **53** (1963), 317–323.

A coherency matrix of a light beam is introduced on the basis of the general theory of stationary stochastic processes with orthogonal increments. The Stokes parameters are re-interpreted as power spectral densities and their generalizations for $N \times N$ systems are studied. The transfer function matrix of a non-image-forming optical instrument is also discussed.

In the first part of this paper, the author distributes compliments and also provides a good deal of criticism of earlier work (including some by the reviewer) relating to the representation of a light beam by a coherency matrix.

In the reviewer's opinion the criticism reflects the following viewpoints: (1) That it is always better to use a frequency domain rather than a time domain representation (the two representations being related via Fourier transforms), (2) That it is preferable to use a real rather than a complex representation of the electic field, and (3) That it is always better to employ ensemble averaging rather than time averaging. *E. Wolf* (Rochester, N.Y.)

Zur Frage der Reversibilitätsprinzipien in der Optik. Eine Bemerkung zu einer Arbeit von Antonin Vašíček.
Z. Physik **166** (1961/62), 257–260.

From the author's summary: "In contrast to the view expressed by Vašíček, this paper attempts to show that there is only one principle (not two) of reversibility in optics, namely, the one which Vašíček attributes to Vlasow." *E. Wolf* (Rochester, N.Y.)

Hauser, H. 6791
Optische Übertragung bei partiell-kohärenter Beleuchtung. I. Die Grenzen der linearen Übertragung.
Optica Acta **9** (1962), 121–140.

This paper is concerned with optical imaging in partially coherent illumination. As is well known in such cases, the relation between the intensity (and also the phase) of the object and the image distribution is not linear. Some estimates of the non-linear contributions of the object structure are obtained. The results are illustrated by several examples, including observation of phase objects by the use of Zernike's phase contrast method. *E. Wolf* (Rochester, N.Y.)

Hauser, H. 6792
Optische Übertragung bei partiell-kohärenter Beleuchtung. II. Die Übertragungstheorie mehrstufiger Abbildungssysteme.
Optica Acta **9** (1962), 141–148.

This investigation is closely related to that of the preceding paper [#6791]. It is mainly concerned with transmission properties of optical systems composed of two or more lenses. Imaging of transilluminated, as well as self-luminous, objects is considered. *E. Wolf* (Rochester, N.Y.)

Parrent, George B., Jr.; Shore, Robert A.; Skinner, Thomas J. 6793
On the mutual coherence function in an inhomogeneous medium.
J. Mathematical Phys. **3** (1962), 678–684.

This paper is concerned with the behaviour of the second-order coherence function $\Gamma_{12}^{(\tau)}$ (known as the mutual coherence function) of a stationary scalar wavefield in an inhomogeneous medium. It is shown that Γ obeys two wave equations which are natural generalizations of the wave equations well known (but not mentioned) in the corresponding theory for propagation in homogeneous media. Approximate expressions for Γ in a field propagated from a plane source are derived in terms of Green's functions. Propagation in a statistically homogeneous medium is studied in some detail. *E. Wolf* (Rochester, N.Y.)

Barakat, Richard 6794
Stochastic generalization of the Green-Wolf complex scalar potential of electromagnetic theory.
J. Opt. Soc. Amer. **53** (1963), 252–255.

In a paper by Green and the reviewer [Proc. Phys. Soc. Sect. A **66** (1953), 1129–1137; MR **22** #6385a] a new complex scalar potential for representing an electromagnetic field in free space was introduced. In a subsequent paper [the reviewer, Proc. Phys. Soc. 74 (1959), 269–280; MR **22** #6385b] some properties of this new representation were discussed. The present paper considers a statistical ensemble of such potentials for representing a stochastic electromagnetic field. Use is made of the spectral representation theorem of Cramér and Kolmogorov. Some results relating to the average energy density and the average energy flow vector are obtained. *E. Wolf* (Rochester, N.Y.)

Denisse, J. F.; Delcroix, J. L. 6795
★Plasma waves.
Translated from the French by Marcel Weinrich and David J. BenDaniel. Interscience Tracts on Physics and Astronomy, No. 17.
Interscience Publishers [John Wiley & Sons], New York-London-Sydney, 1963. xii + 143 *pp.* $7.75.

The subject of waves in plasmas is one that is complicated in itself, and these complications have been frequently aggravated by problems of notation. Several books on the subject have appeared recently and have been invaluable in introducing some order into a rather tangled subject. The present book is a translation from a recent French text which sets out to describe plasma wave motion "within as general and systematic a framework as possible". Lest this phrase be misinterpreted, it should be made clear that the authors have adopted a somewhat restricted approach to their subject. There are many important topics connected with plasma wave motion that are not to be found; to give but one example, there is no discussion of the Landau damping of longitudinal plasma waves. None the less, the authors have organized their material well and this little book is a valuable introduction—but no more than that—to the subject.

In Chapter I the plasma is characterised by the two-fluid equations; from these and the Maxwell equations, the dispersion relation for plane waves is obtained. This relation is then examined in special cases for the study of

transverse and longitudinal waves in a plasma; in the latter case both electron plasma oscillations and the low-frequency ion oscillations are discussed briefly. Later chapters deal with the presence of a transverse magnetic field in the plasma and the more complicated situation arising from the now coupled transverse and longitudinal motions. The last two chapters discuss briefly wave propagation in cold plasmas (Appleton-Hartree theory) and low-frequency magnetohydrodynamic waves.

Karczewski, B. 6796

Coherence theory of the electromagnetic field. (Italian summary)

Nuovo Cimento (10) **30** (1963), 906–915.

The complex degree of coherence of an optical wavefield has previously only been defined within the context of a scalar representation of the field. In the present paper a generalization is suggested, which is applicable to any stationary quasi-monochromatic electromagnetic field. This generalization is suggested by the results of a theoretical analysis, based on vectorial diffraction theory, of a two-beam interference experiment. The generalized degree of coherence is expressible in terms of the trace of the second-order electric correlation matrix of the field. Relation of the present investigation to that of K. Germey [Ann. Physik **10** (1962), 141–152] is briefly discussed.

De Socio, Marialuisa 6798

Su alcune questioni di unicità in elettromagnetismo.

Boll. Un. Mat. Ital. (3) **19** (1964), 146–152.

L'autore dimostra il teorema di unicità per le soluzioni delle equazioni di Maxwell (con le usuali condizioni iniziali e al contorno) in un dominio limitato o illimitato, qualora la densità di corrente sia funzione, anche non lineare, del campo elettrico e del campo magnetico. Dal teorema, valido per tutti i valori (positivi e negativi) del tempo, si deduce che, in un dominio limitato in cui non entra nè si produce energia, un campo elettromagnetico può annullarsi solo dopo un tempo infinito.

Sopra alcune proprietà del campo elettromagnetico generato dal moto iperbolico. (English summary)

Riv. Mat. Univ. Parma (2) **4** (1963), 127–136.

Author's summary: "The electromagnetic field generated by the hyperbolic motion of a charge presents, at first sight, some strange properties, from which a few authors inferred the absence of radiation. One of these properties is as follows: The magnetic field at the instant $t=0$ is zero everywhere in the whole space, although the particle is moving in the whole interval $(-\infty, 0)$ with accelerated motion. In this article the author gives a new proof of this property using a method by which it is also possible to demonstrate that this property is characteristic of the hyperbolic motion. This new method puts in a clear light the fact that it is completely unjustified to infer the absence of radiation."

Chen, Yung Ming 6801

On scattering of waves by objects imbedded in random media: Stochastic linear partial differential equations and scattering of waves by conducting sphere imbedded in random media.

J. Mathematical Phys. **5** (1964), 1541–1546.

The author considers a medium for which both the operator L fixing the left-hand side $L(u)$ of a very general wave equation, and the right-hand side g representing the source distribution, depend on a random parameter q. Both L and g are given in terms of expansions with respect to a small quantity ε. The resulting formal equation, up to second-order terms, for the expectation value $\langle u \rangle$ constitutes an extension of the corresponding equation of Keller's theory for a random medium with a non-random source distribution. The general equation is further worked out for a medium with a refractive index which can be represented by the product of a non-random (inhomogeneous and non-stationary) factor and another random factor.

The theory is applied next to the scattering of a plane wave by a perfectly conducting sphere imbedded in a random medium. This special case amounts to a wave equation for $\langle u \rangle$ which contains an integral term representing the interaction between the scattering sphere and the surrounding random medium. An examination of the integral term with the aid of a Watson transformation (applied to the Green's function associated with the scattering problem) shows that the integral term can be neglected for large values of ka (ratio of the circumference of the sphere and the wavelength); its neglect for small ka proves to be trivial. The remaining terms of the wave equation for $\langle u \rangle$ can be interpreted with the aid of an effective refractive index $\tilde{n}$ of the random medium.

Mathur, N. C.; Yeh, K. C. 6802

Multiple scattering of electromagnetic waves by random scatterers of finite size.

J. Mathematical Phys. **5** (1964), 1619–1628.

This paper treats the scattering of a plane electromagnetic wave incident on a half-space of identical, similarly oriented, randomly positioned scatterers. The general theory follows very closely the work of Waterman and Truell on scalar scattering [same J. **2** (1961), 512–537; MR

22 #B768], with obvious changes from scalars to vectors and dyadics. The case of spherical scatterers (having ε and μ) is treated in detail. Using the Mie theory of vector scattering, the authors consider: (a) sparsely packed spheres, where the exciting field on a particle is taken to be the incident field; and (b) dense packing in which the exciting field is found by the truncation of a certain hierarchy of integral equations. Among the results obtained are expressions for the refractive index, transmission and reflection coefficients for the loosely packed case, and a verification of the extinction theory for closely packed scatterers. Various special cases are considered, for which agreement is obtained with the results of other authors.

CLASSICAL THERMODYNAMICS, HEAT TRANSFER

Morozova, T. V. 6803

Asymptotic inequalities applicable to certain thermodynamic functions. (Russian)

Ukrain. Mat. Ž. **15** (1963), 71–76.

Ergodic theorems of statistical mechanics are discussed in general terms as asymptotic relations between volumes and integrals over specified parts of related spaces. The author then gives a detailed proof of a relation whose formal expression is

$$\frac{1}{N}\log\left\{\iint\cdots\int dx_1 dx_2\cdots dx_N\right\}-\int\rho(x)\log\{1/\rho(x)\}\,dx\to 0$$

as N tends to infinity. The integral on the left represents the volume where certain "distribution functions" lie within prescribed limits. The function $\rho(x)$ is determined by the same set of distribution functions.

A. J. Macintyre (Cincinnati, Ohio)

Giulianini, Arturo 6804

Un contributo allo studio della propagazione del calore in una particolare regione cilindrica.

Atti Accad. Sci. Ist. Bologna Cl. Sci. Fis. Rend. (11) **9** (1961/62), *no.* 2, 79–100.

The author considers two problems: (a) the temperature history in a cylindrical region moving with constant axial velocity under a given initial temperature distribution and with all its surfaces at zero temperature; (b) the same region, axial velocity zero, under a prescribed distribution of constant heat sources. *B. A. Boley* (New York)

Glansdorff, P.; Dekeuster, E.; Haesendonck, Y. 6805

Application du potentiel local de production d'entropie à la recherche de distributions stationnaires de températures et de concentrations. (English summary)

Acad. Roy. Belg. Bull. Cl. Sci. (5) **50** (1964), 60–73.

Authors' summary: "The authors use the local potential of entropy production introduced by one of them and by I. Prigogine to derive a variational method allowing them to obtain stationary distribution laws. A comparison is established between several processes of approximation, and a generalization of the Rayleigh-Ritz method is introduced (self-consistent method). The one-dimensional and bidimensional problems in the field of heat conductivity are approached for a thermal conductivity depending on temperature. Similarly the same processes are then applied to the case of the one-dimensional problem of diffusion associated to a bimolecular chemical reaction."

QUANTUM MECHANICS

See also 6092, 6180, 6272, 6328.

Blokhintsev, D. I. [Blohincev, D. I.] 6806

★Quantum mechanics.

Translated from the third and fourth Russian editions by J. B. Sykes and M. J. Kearsley.

D. Reidel Publishing Co., Dordrecht, 1964. xvi+535 *pp.* *Dfl.* 53.00; $14.85.

This outstanding textbook has so far had several editions, both in the original Russian [e.g., *Foundations of quantum mechanics* (Russian), 3rd ed., Gosudarstv. Izdat. "Vysšaja Škola", Moscow, 1961; MR **24** #B1896] and in other foreign languages. A German translation has been reviewed [*Grundlagen der Quantenmechanik*, Deutscher Verlag der Wissenschaften, Berlin, 1953; MR **16**, 430].

The level of this book goes somewhat beyond that of a first introduction to quantum theory, and covers several topics which are usually treated in an intermediate graduate course. The primary concern of the author is to provide the student with a clear and correct understanding of both the physical basis and the mathematical formalism of quantum theory. The goal of clarity and unambiguity is achieved in an exemplary manner indeed.

After a historical review concerning the origins of quantum theory, the fundamental principles are outlined in great generality and much of the mathematical framework is illuminated in connection with representation theory. Quantum dynamics, however, is given a somewhat too short treatment. The next two chapters discuss the motion of particles in potential fields and in the electromagnetic field. This is followed by the brief theory of angular momentum. Stationary perturbation theory for bound states is the next topic, followed by an outline of collision theory and transition probabilities. By way of application, emission, absorption, and the scattering of light, passage through potential barriers, the highlights of the many-body problem (including the discussion of systems of identical particles) are given. After an introduction to second quantization, further applications follow, such as multi-electron atoms, formation of molecules, magnetic phenomena, and some comments on nuclei and elementary particles. In the last chapter a review of the fundamental ideas is given, together with an excursion into ideology.

This book will prove to be a useful addition to the existing spectrum of texts on quantum theory.

P. Roman (Boston, Mass.)

Clutton-Brock, M. 6807

Feynman's kernel and the classical path.

Proc. Cambridge Philos. Soc. **61** (1965), 201–205.

Author's summary: "The quantum mechanical kernel $K(q'', t''; q', t')$ in Feynman's form of a sum over paths is evaluated by means of the canonical transformation to the

system Q, P for which the Hamiltonian vanishes identically. The kernel is found to be completely determined by the classical paths, and is given by

$$K(q'', t''; q', t') = A \sum_c \frac{\partial(Q, P)}{\partial(q', q'')} \exp\left[\frac{i}{\hbar} S(q'', P, t''; q', P, t')\right].$$

The sum is over all classical paths leading from q' at t' to q'' at t''. $S(q'', P, t''; q', P, t')$ is the classical action along the classical path characterized by the constant momentum P." *A. Peres* (Haifa)

Dubrovskiĭ, V. A.; Skuridin, G. A. 6808

Asymptotic expansions in wave mechanics. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 848–870.

The authors investigate asymptotic expansions for the partial differential equations of wave mechanics with a small coefficient (Planck's constant, $\hbar$) at the highest derivative by means of an unified asymptotic method, which can be applied also to analogous equations in other fields of mathematical physics. The essence of the method consists of the following: the reciprocal of the small coefficient ($1/\hbar$) is considered a constant of separation of variables and a new variable (the action) is introduced on the basis of physical considerations.

Schrödinger's, Klein-Gordon's, and Dirac's equations are transformed to the five-dimensional form with the action as the fifth coordinate. The asymptotic series for the five-dimensional equations as $\hbar \to 0$ are obtained and Cauchy's problem (scattering problem) is solved. The relation between the asymptotic expansions and the theory of perturbation is established. In the case of Schrödinger's equation, the results obtained are used to derive the formulae for the motion of a wave packet and to study the transition from wave mechanics to classical mechanics.

Y. Shimizu (Tokyo)

Goldberger, Marvin L.; Watson, Kenneth M. 6809

Measurement of time correlations for quantum-mechanical systems.

Phys. Rev. (2) **134** (1964), B919–B928.

Correlations in a time series of measurements in quantum-mechanical systems exist by virtue of the incomplete precision of measurements, or, more generally, their incompleteness relative to the set of measurements required to define the dynamical state of the system. Suppose the method of measurement to be so well-designed that phase relations between different state vectors compatible with the same result are to some extent unaffected by the process. Then the values, before and after measurement, of unmeasured variables will be correlated. With some qualifications, the authors assume the ideal situation to be that of maximum overlap between the wave functions before and after measurement, and they call this assumption "the principle of least interference". They also use the term "morally best", quoted from a private communication with E. P. Wigner. (The reviewer considers it semantically careless thus to adopt into science a term belonging to the area of ethics, an area which needs protection from the encroachment of science.) In simple cases at least, this principle is equivalent to exact preservation of the phase relations referred to above.

Subject to this principle, the authors develop an expression for the correlation function of two observables measured at different times. They also extend their results to the case in which the measurement is not instantaneous, assuming that operators for the observables measured then have the form

$$\mathcal{J}(t) = \int_{-\infty}^{t} L(t-\tau) J(\tau)\, d\tau,$$

where J is an instantaneous operator (i.e., of the usual type), and L is of the nature of a response function. Various cases of measurements of this kind are discussed. The most important is that in which it is shown that through the use of a composite detector, it is possible to study fluctuations having a period much shorter than the response time of an individual detector.

The final application is to a measurement of the Hanbury-Brown and Twiss type, proposed by Fano [Amer. J. Phys. **29** (1961), 539–545]. A result essentially equivalent to Fano's is derived.

A. Siegel (Boston, Mass.)

Moldauer, P. A. 6810

Problem of measurement.

Amer. J. Phys. **32** (1964), 172.

Attention is directed to earlier work by Wigner on the theory of measurement in quantum mechanics [e.g., same J. **31** (1963), 6–15; MR **27** #1112], in which the conceptual difficulties associated with the link between measurement and observation are emphasized. Rather than submit to the solipsism which is claimed to be implicit in these considerations, a structure is devised in which the wave-function can be subjective, while the physical universe remains objective. The statistical interpretation is central to the discussion. *H. W. Lewis* (Madison, Wis.)

Moses, H. E. 6811

A note on the equivalence of certain realizations of boson annihilation and creation operators due to K. O. Friedrichs.

Comm. Pure Appl. Math. **17** (1964), 355–356.

In his book [*Mathematical aspects of the quantum theory of fields*, Interscience, New York, 1953; MR **15**, 80] K. O. Friedrichs indicated how to construct certain families of boson annihilation and creation operators which differed from one another by the operation of multiplication by a scalar function. In the present note it is shown that two such sets of operators are unitary equivalent if and only if the scalar function is square integrable with respect to a certain measure occurring in Friedrichs' original definition. (In the opinion of the reviewer, the argument is incomplete because it does not specify the domains of the unbounded operators involved.)

A. S. Wightman (Princeton, N.J.)

Roos, Matts 6812

On the construction of a unitary matrix with elements of given moduli.

J. Mathematical Phys. **5** (1964), 1609–1611.

The author investigates the problem of finding a unitary $n \times n$ matrix (U_{jk}) when the moduli $u_{jk} = |U_{jk}|$ are given.

If D_1 and D_2 are diagonal unitary matrices, D_1UD_2 has the same u_{jk} as U. Thus the author considers the problem

of determining all U for given u_{jk} up to a phase transformation $U \to D_1 U D_2$. The author exhibits a concrete method of determining U_{jk} from given u_{jk} for the case of $n=4$. It is indicated that the method works for general n in principle. The author divides unitary matrices into two classes, regular and irregular. It is asserted (Theorem) that a regular unitary matrix is determined by the u_{jk} up to a phase transformation.

The reviewer feels that the author's discussion is incomplete and, in particular, the theorem is not valid in the form stated, because of an explicit counterexample. In general, $\cos\gamma_{13}$ is determined (as a function of θ_{23}) from (10) of the paper. However, a given value of $\cos\gamma_{13}$ has two solutions γ_{13} in the regular case, which differ in sign, and they give rise to different U's which are not related by a phase transformation. In the irregular case ($|\cos\gamma_{13}|=1$), this ambiguity does not occur. Other points which are not substantiated are the uniqueness of solution of equation (11) for a regular case and the assertion that irregular matrices are not completely determined by the u_{jk} up to a phase transformation. In fact, if we restrict U_{jk} to be real (completely irregular case with $|\cos\gamma_{jk}|=1$ for all j, k), then the u_{jk} determine U_{jk} up to a phase transformation, in general. *H. Araki* (Kyoto)

Zucker, I. J. 6813

Quantum mechanics of the isotropic three-dimensional anharmonic oscillator.

Proc. Cambridge Philos. Soc. **60** (1964), 273–278.

The author treats the calculation of the eigenvalues of a three-dimensional, anharmonic oscillator with a spherically symmetric potential which has a power series expansion. He shows that when the power series expansion of the potential has terms of even order only; then a method of McWeeney and Coulson [same Proc. **44** (1948), 413–422; MR **10**, 225] yields the eigenvalues to any desired degree of accuracy. He treats in some detail the case where $V=ar^2+br^4+cr^6$. In essence, his technique is to expand the exact wave function in terms of the wave functions of the harmonic oscillator. This yields a secular determinant of infinite order, which can then be solved by successive approximations. *J. McKenna* (Murray Hill, N.J.)

Aramaki, Seiya 6814

On the forward peak of scattering in the high energy limit.

Progr. Theoret. Phys. **30** (1963), 265–266.

This short note presents a simple proof that the forward scattering amplitude $A(s, \cos\theta=1)$ must dominate in the high-energy limit provided (i) there is a finite domain of analyticity in the $\cos\theta$ plane at $s=\infty$ enclosing the real region $-1+\varepsilon<\cos\theta<1-\varepsilon$ $(\varepsilon>0)$, and

(ii) $$\int^{\infty} \frac{\operatorname{Im} A(s,1)}{|A(s,1)|^2}\frac{ds}{s}<\infty.$$

The author justifies the latter condition by an appeal to low-energy pion-nucleon data. This implies a once subtracted dispersion for $A(s,1)$ (at least for the non-spin, non-isotopic-spin flip amplitude), and hence (ii). This condition may also be true in a more general context, but is not satisfied by an arbitrary Herglotz function.

Arthurs, A. M.; Holt, A. R. 6815

Rotating coordinates in scattering theory.

Proc. Phys. Soc. **82** (1963), 1073–1074.

In a paper by Arthurs and Lewis [Proc. Roy. Soc. Ser. A **269** (1962), 585–588; MR **26** #1053] it was shown that if H is the Hamiltonian of a scattering system, and if $H'=e^{iu}He^{-iu}$ is a unitary transformation of H, then under appropriate circumstances, the corresponding exact cross-sections σ and σ' are equal. In this letter it is shown that, even though the exact cross-sections σ and σ' are equal, in first Born approximation the corresponding cross-sections σ_B and σ_B' can differ enormously. The authors discuss a case in which σ_B' even diverges although σ_B remains finite.

Domokos, G. 6816

High energy scattering in systems with anomalous thresholds.

Acta Phys. Polon. **24** (1963), 345–350.

In this paper the author considers the high-energy behaviour of the scattering amplitude in the presence of anomalous thresholds. He considers mainly $\pi\Sigma$ and πd scattering, in which cases the amplitudes are determined by the Pomeranchuk pole, just as in cases without anomalous thresholds. In the case of scattering on a nucleus, the amplitude is proportional to the atomic number. The role of many-nucleon intermediate states is briefly discussed.

Scattering wavefunctions for a Dirac particle in a central potential.

J. Mathematical Phys. **5** (1964), 1645–1651.

Authors' summary: "The scattering wavefunction for a Dirac particle in a central potential is written in terms of a matrix acting on a plane-wave spinor whose momentum direction $\hat{p}$ and polarization direction are the assigned directions for the asymptotic incident plane wave. The matrix involves four functions, independent of polarization direction, which multiply the matrices 1, $\alpha\cdot(\hat{p}-\hat{r})$, $\alpha\cdot(\hat{p}+\hat{r})$, $\hat{p}\wedge\hat{r}\cdot\sigma$. Differential relations for these four functions are directly obtained and asymptotic relations are given. In particular, the function multiplying $\alpha\cdot(\hat{p}+\hat{r})$ is asymptotically zero, so the potential scattering formulation is identical with that given previously for the Coulomb potential. The scattering wavefunction is a solution of the general differential relations subject to appropriate boundary conditions. For the Coulomb potential, these differential relations simplify, and an iterative solution is developed based on a Green's function technique with the Sommerfeld-Maue approximation as the zero-order solution." *T. Scattering of electromagnetic waves by a ferrite in a waveguide.
J. Mathematical Phys. 5 (1964), 1261–1272.
Authors' summary: "As for any multichannel scattering problem, variational techniques can be utilized in the determination of the elements of the scattering matrix or of the equivalent network elements for a gyromagnetic obstacle in a waveguide. As always, however, it can be quite difficult to interpret numerical results which in general are neither upper nor lower bounds. A variational bound originally developed for the determination of the phase shift for a given angular momentum in a quantum mechanical central potential scattering problem is here adapted to the solution of a transversally magnetized, lossless ferrite slab in a rectangular waveguide propagating only one mode, the TE_{10} mode. With a simple trial function and with the aid of a comparison scattering problem which need not be tensor in character (so that the determination of upper and lower bounds is not really difficult), close bounds are obtained on $\cot \eta_e$ and $\cot \eta_o$, the cotangents of the real uncoupled phase shifts associated with the even and odd standing waves, respectively. The bounds obtained on $\cot \eta_e$ and $\cot \eta_o$ determine bounds on the equivalent π network. A second variational bound, which can be simpler to apply and which can be applied to a wider class of problems, is also developed. This, too, is an adaptation of a formalism originally introduced in quantum mechanical scattering problems, and depends upon a consideration of the spectrum of the fundamental operator of the theory, the Hamiltonian in the quantum mechanical case and an analogue thereof in the electromagnetic case."

Some remarks concerning a pathological matrix of interest in the inverse-scattering problem.
J. Mathematical Phys. 5 (1964), 1547–1554.
This paper is a discussion of some properties of an infinite matrix which arose in R. G. Newton's investigation of an inverse scattering problem. The motivation for the author's analysis apparently rests on the fact that he was previously unaware that it is possible for an infinite matrix to annihilate a vector which does not belong to its range. The author points out that since the matrix in question has this property, the inverse scattering problem of Newton does not have a unique solution.

Remarks concerning reciprocity in quantum mechanics.
J. Mathematical Phys. 5 (1964), 435–441.
In classical physics "reciprocity" generally refers to a symmetry condition on a Green's function, while in quantum mechanics reciprocity usually refers to a symmetry condition on scattering amplitudes. In this paper the authors generalize and combine these two ways of looking at reciprocity. Let H be the Hamiltonian matrix (which need not be Hermitian), and let Ψ be the Green's function (matrix) satisfying $(H-E)\Psi = I$. If U is a unitary matrix, we define $\tilde{H} = UH^TU^\dagger$ and $\tilde{\Psi} = U\Psi^TU^\dagger$, where H^T denotes the transpose and $U^\dagger$ denotes the Hermitian conjugate. Then it is shown that if H has the invariance property $\tilde{H} = H$, the Green's function also satisfies $\tilde{\Psi} = \Psi$. If ψ^a is a state vector, let $\psi^{\tilde{a}} = U\psi^{a*}$, where * denotes complex conjugation. Then the invariance of H further implies the relations between the matrix elements $H_{a\beta} = H_{\tilde{\beta}\tilde{a}}$, $\Psi_{a\beta} = \Psi_{\tilde{\beta}\tilde{a}}$, where $H_{a\beta} = \langle\psi^a|H|\psi^\beta\rangle$, etc. Finally, it is shown that the reciprocity condition satisfied by the Green's function implies that a symmetry relation is satisfied by the elements of the reaction matrix.

Chakrabarti, A. 6825
Applications of the Lorentz transformation properties of canonical spin tensors.
J. Mathematical Phys. 5 (1964), 1747–1755.
Author's summary: "Some applications of the Lorentz transformations of relativistic spin tensors in the canonical representation are discussed. The problem of precession of polarization is discussed in Sec. 2. It is shown that the kinematical equation, obtained quite simply, already contains the 'Thomas factor'. In Sec. 3, applications to polarization

analysis of decay products are considered. The canonical form of S-matrix elements are used and multipole parameters for successive decays of the type $a \to b+c$ are obtained in an arbitrary frame in a relatively simple way. The exact relativistic way in which the multipole parameters depend, in an arbitrary frame, on the particle momenta are discussed for decays of the type $a \to b+c+d$. While the canonical representation is used mainly, the corresponding technique in the spinor representation is discussed."

On the behaviour of Green functions at small distances. (Russian summary)

Acta Phys. Acad. Sci. Hungar. **17** (1964), 107–114.

The asymptotic behaviour of Green's functions at small distances is examined in terms of a scalar field model of the four-point function, with the help of the Bethe-Salpeter equation. The Bethe-Salpeter kernel for the lowest non-vanishing approximation is studied, and a close connection is found between the behaviour of the Green's function at small distances and the type of interaction adopted. It is found that according to whether the dimension of the coupling constant involved is a negative power of length, a dimensionless power of length or a positive power of length, the theory corresponds to a "super-renormalizable" theory, a renormalizable theory or an unrenormalizable theory, respectively. For the latter type of theory the Bethe-Salpeter equation gives a well-defined solution, but with an essential singularity at the origin.

Dowker, J. S. 6828

A note on Salam's compositeness conditions.

Nuovo Cimento (10) **29** (1963), 551–554.

It has recently been noted that particles are composite when their wave-function renormalization constants are zero. Salam [Nuovo Cimento (10) **25** (1962), 224–227] has further pointed out that the renormalization constants for the dissociation vertices of the composite particles are also zero. In the article under review these conditions for composite particles are examined within the context of the Zachariasen model. The model consists of two particles A and B and one distinct antiparticle $\bar{B}$. The Lagrangian is constructed in such a way that the only basic interactions are $A \to B+\bar{B}$ and $B+\bar{B} \to B+\bar{B}$, the bare coupling constants of which are denoted by g_0 and λ, respectively. The bare mass of the particle A is denoted by M_0. The model leads us to the following conclusions. The propagator of the particle has two singularities, which correspond to two physical masses (M_1, M_2). When the limit $g_0 \to 0$ is performed, one of two masses (say M_1) tends to the bare mass M_0 and the other (M_2) to a mass value M', which is the mass of a composite state. In this limit we find also that both the wave function renormalization constant Z_3 and the vertex renormalization constant Z, for the composite state, tend to zero, in agreement with the above-mentioned conditions for the composite particles. The reviewer would like to note that a similar consideration has been presented also by T. Muta [Progr. Theoret. Phys. **30** (1963), 223–235; MR **27** #6540] by making use of the double Lee model.

H. Umezawa (Tokyo)

Durand, Loyal, III 6829

Remarks on the electromagnetic interactions of massless particles.

Phys. Rev. (2) **128** (1962), 434–440.

This article is aimed at examining a limit of applicability of the Case-Gasiorowicz Theorem, which states that a massless particle of spin larger than or equal to one cannot be charged.

To derive this theorem, the author considers the electromagnetic vertex of the massless charged fields and concludes that the vertex should be zero as long as the spin is larger than or equal to one. The argument is developed in the Breit system, where the momenta of the initial and the final particles are equal in magnitude but oppositely directed. Let us call the direction of the initial momentum the third direction. Then, the helicity conservation law leads to the conclusion that the electromagnetic vertex of the current orthogonal to the third direction is zero when the spin of the charged particle is not equal to $\frac{1}{2}$. The third component of the vertex also appears to be zero because of the invariance of the theory under the reflection and time inversion. Expanding the fourth component of the vertex in terms of the electric multipole moments, one finds that the electromagnetic interaction should contain derivatives of order $2\mathscr{S}+1$ (for the integer spin $\mathscr{S}$) or $2\mathscr{S}-1$ (for the half-integer spin). The coupling constant of such an electromagnetic interaction cannot be dimensionless when $\mathscr{S} \geq 1$.

Thus the conclusion is that the massless particle of spin ≥ 1 cannot be charged as long as we do not introduce any constant of dimension of mass. This means that massless particles can be charged when they interact with massive particles. An example is presented in the case of a massless vector field.

Ginzburg, I. F. 6830

Inelastic interactions of high-energy particles in renormalized strong-interaction theories.

Ž. Èksper. Teoret. Fiz. **44** (1963), 500–513 (*Russian. English summary*); *translated as Soviet Physics JETP* **17** (1963), 342–350.

Author's summary: "The expansion of the Green's functions and differential cross sections for inelastic processes in powers of the reciprocal of the energy $1/s$ is deduced in renormalized theories. In some cases the first terms of the series are the usual peripheral diagrams, whereas in other cases they are somewhat more complicated. The region

of applicability of the results obtained is much larger than that for the usual pole theory of peripheral collisions."
H. Umezawa (Tokyo)

Kamefuchi, S.; Umezawa, H. 6831
The mass of gauge particles and the self-consistent method of quantum field theory. (Italian summary)
Nuovo Cimento (10) **32** (1964), 448–468.

Authors' summary: "The aim of the present paper is to apply the self-consistent method based on inequivalent representations, which was developed in our previous papers, to vector fields in order to see whether the so-called gauge theories can allow nonzero masses for gauge vector fields. The Stueckelberg formalism is exclusively used, which is most convenient for our present purpose. It is shown that the representations for vector fields with nonzero mass are inequivalent to those for vector fields with zero mass even when the cut-off momentum and the normalization volume are finite. In quantum electrodynamics it can be shown that the photon cannot have any stable sister particle with nonzero mass. However, it is possible that there exists such a sister particle which is unstable. Our consideration is further extended to the Yang-Mills field as a simple example of multiplet gauge fields. It can be shown that the three components of this field cannot have an equal, nonzero mass simultaneously, but that they can have nonzero masses in an asymmetric way such that at least one of the three masses is different from the others. Most conclusions reached here seem to be valid in more general cases of gauge theories."

{Reviewer's opinion: The controversy as to whether gauge invariance implies zero-mass particles (Goldstone's theorem) is due in part to the different concepts meant by gauge invariance. For example, the theorem can only be proved if there is a positive definite metric; the present paper is one in which there is an indefinite metric, just as there is in the theory of quantum electrodynamics in two dimensions (Schwinger's model). The present paper is not at all rigorous, but its conclusions are not in conflict with Goldstone's theorem.} *R. F. Streater* (London)

McEwan, J. 6833
Representation of particle states in quantum field theory.
Phys. Rev. (2) **132** (1963), 2353–2362.

This article is aimed at proposing a definition of a state representing an unstable particle. Although a state of a stable particle can be defined in terms of its asymptotic fields, such a definition cannot be applied to the case of unstable particles, because there is no asymptotic field corresponding to unstable particles. To consider an unstable particle produced in a finite region of space-time $V(x)$, the author introduces a test function $X_V(x)$ with the region V as its support. The state of an unstable particle is defined by an integral equation which is derived from a relation for a stable particle with a wave packet $f(x)$ by the replacement $f \to X_V$. The state thus defined depends on the choice of the function X_V. This reflects the fact that the state of an unstable particle should depend on the details of the preparation of the particle. For this reason the function X_V is called the preparation function. Naively speaking, the preparation function plays a role of separating a narrow domain around the resonance mass from the whole region of the continuous mass spectrum. The decay law of the state of the unstable particle deviates from the exponential decay law at very long times and depends on the details of the preparation, in agreement with Schwinger's conclusion [Ann. Physics **9** (1960), 169–193; MR **22** #2362]. *H. Umezawa* (Tokyo)

Ogievetskij, V. I. [Ogieveckiĭ, V. I.]; Polubarinov, I. V. 6834
Interacting fields of spin 1 and symmetry properties.
Ann. Physics **25** (1963), 358–386.

As is well known, any massive free field of the vector type satisfies an equation of the form $\partial_\mu \phi_\mu = 0$ when it belongs to the unit spin representation of the homogeneous Lorentz group. This equation is satisfied by an interacting vector field when and only when the source of the vector field conserves ($\partial_\mu j_\mu = 0$). When this equation is not satisfied, it may be expected that the wave function of the interacting vector field is a superposition of wave functions of spinless and unit spin particles, although, even in such a case, there exists an equation of the form $\partial_\mu \phi_\mu = F(\phi, \psi)$ which reduces the number of degrees of freedom of the field to three. Here ψ stands for the field operators of the source of the vector field.

In the article under review the author proposes a hypothesis which states that any interacting field should possess a definite spin. This hypothesis leads to the conclusion that the source current j_μ of any vector field should conserve and therefore that the theory should possess some symmetry properties of the type of the Lie group. This conclusion holds even in the case of the massless vector field. In this way the author emphasizes that the symmetry of the nature might be intimately related with the space-time property of the field (i.e., the spin property). Taking this viewpoint, the author presents a detailed consideration of the symmetry properties in cases of interacting fields of spin 0, $\frac{1}{2}$ and 1. *H. Umezawa* (Tokyo)

Bonometto, S. 6835
On gauge invariance for a neutral massive vector field. (Italian summary)
Nuovo Cimento (10) **28** (1963), 309–319.

In the Stueckelberg formalism the massive vector field theory is formulated in a way similar to the quantum electrodynamics. In this formalism are introduced a vector field a_μ and a scalar field b. When the source current of the vector field conserves, the theory appears to be invariant under the gauge transformation $a_\mu \to a_\mu + \partial_\mu \Lambda$, $b \to b - m\Lambda$, where m is the mass of the vector field. In the article under review the author presents a simple and elegant derivation of the Stueckelberg formalism and clarifies an intimate relation between the gauge transformation given above and that in quantum electrodynamics. The argument is based on the fact that the equation $(\Box - m^2)a_\mu = 0$ takes the form of the massless field equation, $\Box^{(5)} a_\mu = 0$, in a five-dimensional space, when we consider only solutions

satisfying $\partial_5{}^2 a_\mu = -m^2 a_\mu$. Here, $\Box^{(5)}$ is the five-dimensional d'Alembertian.

This fact led the author to consider the gauge-invariant theory of "massless" vector field ($\Box^{(5)} a_\mu = 0$, $\mu = 1, \cdots, 5$) in five-dimensional space. It turns out that such a theory is just the Stueckelberg formalism for the massive vector field when we denote a_5 by b. The author also points out that his formulation gives us a simple way of deriving the Ogievetski and Polubarinov formalism for the massive vector field. *H. Umezawa* (Tokyo)

Fermion self-masses and Lehmann's spectral representation. (Russian summary)

Acta Phys. Acad. Sci. Hungar. **17** (1964), 103–106.

Lehmann's theorem provides a connection between the bare mass and the physical mass in terms of the spectral representation. This theorem is extended to the case of the spinor self-coupling on the basis of the spectral representation of the propagator, the field equations and the equal-time anticommutators. In a simplified version of the theorem a typical self-consistent mass equation holds.

Asymptotic properties of dynamical variables in the theory of spinor and scalar meson fields. (Russian)

Ž. Vyčisl. Mat. i Mat. Fiz. **4** (1964), 871–879.

In broad terms this is a study of the propagation of singular solutions of certain fields which are of current interest in quantum-mechanical field theory. It is an extension of an earlier paper by the author [Dokl. Akad. Nauk SSSR **149** (1963), 298–301] on the relation between classical and wave mechanics, here in the sense of study of the characteristic hypersurfaces of differential equations, and of the associated conservation equations. It is stated that the theory is to be interpreted in the sense of the theory of distributions. (Since the analysis is given very compactly in formal tensor notation, it is difficult to extract from it a statement of specific results.)

Stipčević, Zdravko 6841

A generalization of the Hartree method. (Serbo-Croatian summary)

Glasnik Mat.-Fiz. Astronom. Društvo Mat. Fiz. Hrvatske Ser. II **18** (1963), 279–284.

The author uses the variational method to find the energy of a many-body system, using as the trial wave function of a system of $2n$ particles a product of the form

$$\varphi_1(1, 2)\varphi_2(3, 4) \cdots \varphi_i(2i-1, 2i) \cdots \varphi_n(2n-1, 2n).$$

This seems to the present reviewer a rather restricted kind of trial function, and until quantitative results are given of applications of this method, it seems difficult to judge the effectiveness of this approach.

Visconti, A.; Carmona, J. 6843

Structure of field quantities and S-operator. (French and Italian summaries)

Nuovo Cimento (10) **29** (1963), 742–759.

In this article the authors present an elegant formulation of the quantum field theory based on functional techniques. A key role in the formulation is played by a mapping operator which transforms c-number functionals into operator functionals. By making use of the mapping operator, together with the generator for the propagators, the authors succeed in deriving the well-known formulae for the S-matrix and the R-products in an extremely simple manner.

It is suggested that one might find a possible extension of the quantum field theory by introducing the interaction differential operator which relates the generator of the propagator of the free fields to that of the interacting fields. *H. Umezawa* (Tokyo)

Photon emission from a given current.

Norske Vid. Selsk. Forh. (Trondheim) **37** (1964), 69–75.

The problem of photon emission from a current which is a given function of space and time has been treated by many authors since the famous study of the "infrared catastrophe" by F. Bloch and A. Nordsieck [Phys. Rev. (2) **52** (1937), 54–59] and is known to be exactly soluble. The present author expounds an elementary method of solving this problem. *H. Araki* (Kyoto)

Freund, Peter G. O. 6845

The method of complex angular moments in relativistic quantum theory.

Lectures in Theoretical Physics, Vol. VI (Summer Inst. Theoret. Phys., Univ. Colorado, Boulder, Colo., 1963), pp. 459–512. Univ. Colorado Press, Boulder, Colo., 1964.

This interesting article is aimed at the theoretical physicist who has already a knowledge of standard dispersion relation techniques and who wishes to obtain an exposition of the method of complex angular momenta and its main applications to high-energy physics. Potential scattering is omitted from consideration.

After a review of the Mandelstam representation, the interpolation problem for partial wave amplitudes is considered, followed by a detailed discussion of the properties of the interpolating functions. The next chapter presents the theory of Regge poles. Chapter 4 investigates the concept of an "elementary" particle. Finally, high-energy scattering is given a fairly detailed discussion.

P. Roman (Boston, Mass.)

Morey Terry, F. 6846

On the nature of nuclear potentials. (Spanish. English summary)

Rev. Un. Mat. Argentina **22**, 22–37 (1964).

Author's summary: "In the present paper, the explicit form of the potentials resulting from the theories of dispersion relations from the point of view of field theory and potential theory is obtained. The calculations are performed for one of the ten necessary potentials as exposition of the results obtained and of the methods necessary to handle these potentials. The results obtained agree with what one may expect from phenomenological analysis if the spreading of the particles, when proceeding to the non-relativistic limit of a relativistic theory, is taken into account."

This paper is not concerned with the explicit derivation of a nucleon-nucleon potential from field theory by the use of dispersion relations. Rather, it is concerned with the reduction of the wave equation for two Dirac particles interacting through a potential to an equivalent non-relativistic Schrödinger equation.

Rothleitner, J. 6847

Exakte Lösungen von Low-Gleichungen. (English summary)

Z. Physik **177** (1964), 287–299.

Exact solutions of the Low equation are derived for various one-, two-, three- and four-dimensional crossing matrices. The three-dimensional case corresponds to the physical problem of symmetric pseudoscalar pion-nucleon scattering in the static model. The solution for this case is a special one for which the phase shifts satisfy the relation $\delta_2 = (\delta_1 + \delta_3)/2$, which is quite different from what is usually assumed in approximations to the Low equation. The four-dimensional case corresponds to the same physical problem, but exact solutions are found for which $\delta_{13} \neq \delta_{31}$, as well as the case usually assumed where these phase shifts are equal. *J. Andrews, M.; Gunson, J. 6850

Complex angular moments and many-particle states. I. Properties of local representations of the rotation group.

J. Mathematical Phys. **5** (1964), 1391–1400.

The rotation matrices, $D_j^{m,m'}(\alpha, \beta, \gamma)$, are investigated as functions of complex values of their parameters. The rotation matrices of the second kind, $E_j^{m,m'}(\alpha, \beta, \gamma)$, which are related to the $D_j^{m,m'}(\alpha, \beta, \gamma)$ in much the same way as the Legendre functions of the first kind, $P_j(\cos\beta)$, are related to those of the second kind, $Q_j(\cos\beta)$, are also studied. The continuation is made from a definition of these matrix elements in terms of the hypergeometric function. The asymptotic behaviours as the variables $|z| = |\cos\beta|$, $|j|$, or $|m'|$ become large are derived. A generalized Clebsch-Gordan reduction of products of these functions is stated, as well as a completeness relation. Finally, a generalization of the Sommerfeld-Watson transform is given and a theorem allowing the expansion of a square-integrable function, $f(\alpha, z, \beta)$, in terms of the $D_j^{m,m'}$ is proved.

J. T. Cushing (London)

Barut, A. O. 6851

Complex Lorentz group with a real metric: Group structure.

J. Mathematical Phys. **5** (1964), 1652–1656.

The group in question is the group of 4×4 matrices Λ satisfying $\Lambda^* G \Lambda = G$, i.e., the transformations act on the space of complex four-vectors and leave invariant the form $\sum_{j,k} Z_j Z_k G_{jk}$, where G is a diagonal matrix, $G_{11} = -G_{22} = -G_{33} = -G_{44} = 1$. The author studies its subgroup structure, Lie algebra and complex extension (which is A_3 in Cartan's notation), the little groups, the inhomogeneous groups associated, and the group invariants. The

group contains the Lorentz group as a subgroup, and the little group for positive mass is the group U_3.

Apart from the purely mathematical analysis of the group, done here apparently for the first time, the paper is of interest in the current problem of connecting the Lorentz group with an internal symmetry group.

Beltrametti, Enrico 6852

Group theoretical properties of complex angular momenta.

Lectures in Theoretical Physics, Vol. VI (Summer Inst. Theoret. Phys., Univ. Colorado, Boulder, Colo., 1963), *pp.* 155–168. *Univ. Colorado Press, Boulder, Colo.,* 1964.

It is shown that the extension to complex angular momenta of Weyl's method, to obtain expressed representations of the 3-dimensional rotation group, naturally leads to defining two sets of infinite matrices. These sets can be defined in correspondence with the elements of the rotation group, except for certain singularities. Moreover, it is shown that the product of two matrices does not always exist, but if one considers the two sets together, one obtains a typical structure which can describe the product rules of the rotations. *P. Roman* (Boston, Mass.)

Cook, L. F., Jr.; Lee, B. W. 6853

Unitarity and production amplitudes.

Phys. Rev. (2) **127** (1962), 283–296.

Production amplitudes are studied using the Blankenbecler extension of the N/D method. In contrast with the paper of Meetz [same Rev. (2) **125** (1962), 714–728], Jacob-Wick helicity amplitudes are used [Ann. Physics 7 (1959), 404–428; MR **22** #2396] rather than Ciulli-Fischer partial wave amplitudes [Ž. Èksper. Teoret. Fiz. **38** (1960), 1740–1750; MR **22** #7701; ibid. **39** (1960), 1349–1356, MR **22** #13176; Nuovo Cimento (10) **12** (1959), 264–285; MR **21** #6968], which are nonrelativistic. Special care is devoted to the anomalous singularities which require a suitable modification of the N/D method.

The unitarity is stated directly in terms of absorptive parts actually needed in dispersion relations rather than in terms of Cutkosky's generalized unitarity which connects the imaginary part of a graph to its possible partitions [see also Ball, Frazer and Nauenberg, Phys. Rev. (2) **128** (1962), 478–494; MR **29** #5533].

The N/D solution for the T matrix is obtained in the presence of anomalous singularities by analytic continuation in the external masses. The correctness of the procedure is guaranteed, noticing that the T matrix obtained has correct analytic properties, satisfies unitarity, and has the correct discontinuities across anomalous singularities. *S. Ciulli* (Bucharest)

Gribov, V.; Okun', L. [Okun', L.]; Pomeranchuk, I. [Pomeranĉuk, I.] 6854

On processes determined by fermion Regge poles.

Ž. Èksper. Teoret. Fiz. **45** (1963), 1114–1122 (*Russian. English summary*); *translated as Soviet Physics JETP* **18** (1964), 769–774.

The authors show in a simple and elegant manner (not involving partial wave expansions) that if a process is described by fermion Regge poles, then these poles must occur as conjugate pairs in the physical l-plane corresponding to states of opposite parity. They also discuss polarization phenomena for one- and two-pole pairs and deduce relations between cross-sections of processes governed by the same Regge poles.

A. C. Hearn (Oxford)

Halfin, L. A. 6855

Quantum theory of unstable elementary particles.

Dokl. Akad. Nauk SSSR **141** (1961), 599–602 (*Russian*); *translated as Soviet Physics Dokl.* **6** (1962), 1010–1012.

This article considers the decay of unstable elementary particles from the point of view of dispersion theory. The usual description of an unstable particle in terms of a mass and a width is generalized to include a "preparation function" in the case where the width is not negligible compared to the mass. The main result relates the poles of the mass distribution to a dispersion integral over the parameters of the decay law.

★Strong-interaction physics.

A lecture note volume. Frontiers in Physics.

W. A. Benjamin, Inc., New York-Amsterdam, 1964. xi + 154 *pp.* $9.00.

This book consists of two separate lecture course notes which were given at the Middle East Technical University in Ankara during 1962–1963.

The first course by M. Jacob, entitled "An Introduction to the Analysis of Strong-Interaction Processes" covers mainly the phenomenological aspects of pion-nucleon physics and is designed to introduce current notions and mathematical methods for analyzing strong-interaction processes. After a general kinematical introduction and an introduction of partial wave amplitudes, charge independence is discussed and a phenomenological analysis of pion-nucleon scattering is given. This is followed by a survey of other mesons. The next chapter then gives a more systematic introduction to the analysis of pion-nucleon scattering by means of dispersion relation techniques. Finally, the peripheral model and the role of nearby singularities is discussed.

The second contribution, by G. F. Chew, is entitled "Nuclear Democracy and Bootstrap Dynamics" and can be considered as a continuation of the second author's book [G. F. Chew, *S-matrix theory of strong interactions,* Benjamin, New York, 1961; MR **24** #B748], which was published in the same series in 1961. The most significant change in viewpoint is the unequivocal adoption of nuclear democracy as a guiding principle, and the assertion that subtractions can always be avoided and that no arbitrary parameters should appear in the strong interaction S-matrix.

Maximal analyticity of the first and of the second degree is introduced and a non-relativistic model to illustrate these concepts is given. Finally, relativistic bootstrap dynamics is elucidated.

★**Elementary particle physics.**

Addison-Wesley Series in Advanced Physics.

Addison-Wesley Publishing Co., Inc., Reading, Mass.-London, 1964. xiv + 546 pp. $15.00.

Most extensive textbooks in elementary particle physics were written between 1956 and 1960 and were devoted to the study of field theory, with the exception of Roman's, which dealt with the symmetry aspect. With the failure of orthodox field theory to account properly for the mechanics of the strong interactions, the series has been discontinued; a large number of short treatises have appeared in 1963–1964, dealing with new developments and successful new ideas.

The present volume is the first full-length textbook to emerge after this "revolution". Indeed, from many points of view the book is really refreshing: it is extremely close to experiment and is probably the best available description of the phenomenology of high-energy physics. Strong and weak interactions are studied in detail, with full explanations of the ways in which our knowledge and characterization are gained: identifying resonances, their spins and other quantum numbers, etc., e.g., a special chapter is devoted to mass measurements.

Interactions studied in detail include π-N scattering, photoproduction, annihilation, electron scattering, and some strong interactions of strange particles. Weak interactions are studied in great detail, leptonic and non-leptonic.

The strength of this textbook is its interest in the phenomenology; most experimental results stand as of mid-1963, with even some more recent ones. What is entirely missing is the theory. Theoretical covering is as of 1958; topics like the Mandelstam representation and all the related development in dispersion theory, Regge poles, etc., are not dealt with. On the symmetry side, things stop at strangeness, with the whole of SU(3) missing.

To sum up, the book is useful as an introduction to basic phenomena. It can best be used in conjunction with some of the existing paperbacks on the theory.

Y. Ne'eman (Pasadena, Calif.)

Lubkin, Elihu 6858

Possible relationship between electric charge and dual charge.

J. Mathematical Phys. **5** (1964), 1603–1606.

The author speculates on a possible geometro-dynamical approach [D. Finkelstein and C. W. Misner, Ann. Physics **6** (1959), 230–243; MR **22** #2369] for eliminating the particles with fractional charge corresponding to the unphysical triplet representations of SU(3) [M. Gell-Mann, Phys. Lett. **8** (1964), 214–215]. This paper is now superseded by those of A. Komar [Phys. Rev. Lett. **13** (1964), 220–221] and C. R. Hagen and A. J. Macfarlane [Phys. Rev. Remarks on the $|\Delta \vec{I}| = \frac{1}{2}$ rule in weak interactions.

Lectures in Theoretical Physics, Vol. VI (Summer Inst. Theoret. Phys., Univ. Colorado, Boulder, Colo., 1963) *pp.* 169–189. *Univ. Colorado Press, Boulder, Colo.* 1964.

To begin with, a brief survey of the general features of weak interactions is given, stressing some of the yet unanswered questions. Then attention is focussed on special topics related to the $|\Delta \vec{I}| = \frac{1}{2}$ rule, viz., leptonic K-meson decays, strangeness-changing semi-leptonic decays, and non-leptonic decays of strange particles.

P. Roman (Boston, Mass.)

Ryan, C.; Sudarshan, E. C. G. 6862

Representations of parafermi rings.

Nuclear Phys. **47** (1963), 207–211.

Authors' summary. "We consider the operator algebra corresponding to a system consisting of an arbitrary finite number ν of parafermi oscillators with a view to obtaining all irreducible representations of the operator algebra defining it. It is shown that this algebra is isomorphic to the Lie algebra of the orthogonal group B_ν in $2\nu+1$ dimensions. The known results of the representation theory of the orthogonal group are then used to find the representations of the ring of parafermi operators. In particular it is seen that the so-called Green Ansatz for a parafermi ring arises in a natural way and that, in a certain sense, it furnishes the most general 'solution' of the parafermi algebra. The case of a parafermi ring of order 2, which is the simplest non-trivial case, is considered in some detail."

{Reviewer's remark: This article stimulates the question: Is there a type of (second quantized) particle statistics for each Lie algebra?}

Tietz, T. 6864

A new method for finding the phase shifts for the Schrödinger equation.

Acta Phys. Acad. Sci. Hungar. **16** (1963), 289–292.

The author derives several approximate relations between the phase shifts of the radial Schrödinger equation describing scattering by a central potential. The potential $V(r)$ vanishes at infinity more rapidly than the Coulomb potential, and at the origin can be no more singular than the Coulomb potential. Then if the energy and angular momentum are large enough, $\eta_l = \frac{1}{2}(\eta_{l+1} + \eta_{l-1})$. The author shows that this relation is satisfied quite well for a Fermi-Thomas potential. Several other appropriate formulae for $\eta_l - \eta_{l+1}$ and $\eta_{l-1} - \eta_{l+1}$ are also given.

Levine, A. D. 6866

A note concerning the spin of the phonon.

Nuovo Cimento (10) **26** (1962), 190–193.

Vonsovskii and Svirskii [Fiz. Tverd. Tela **3** (1961), no. 7, 2160–2165] have introduced the phonon spin in isotropic media by using the Lagrangian formalism. The present author simply extends the method to a cubic lattice and finds that the phonon spin is well-defined only along certain restricted directions of propagation of the waves.

Fradkin, D. M.; Weber, T. A.; Hammer, C. L. 6869

Coulomb scattering of Dirac particles.

Ann. Physics **27** (1964), 338–361.

Authors' summary: "The continuum Coulomb wave function in the Johnson and Deck form—a matrix operator acting on a plane wave spinor—is discussed. General relations for the elastic differential cross-section, the asymmetry parameters, and the precession and nutation of polarization are developed. An expansion of the asymptotic wave function correct to third order in $\lambda = \alpha Z$ for all Born parameters $\nu = \alpha Z/\beta$ is obtained. This expansion involves a two-parameter function $T(\theta, \nu)$ which in turn may be expanded for small ν to give results previously obtained by Johnson, Weber, and Mullin. On the other hand, a large ν asymptotic expansion of $T(\theta, \nu)$ valid for $|2\pi\nu| > 1$ permits a discussion of the nonrelativistic limit. Both the small and large approximations substantially agree for $|\nu| \simeq \frac{1}{2}$. Consequently, these two approximations may be used to span the whole range of Born parameters. The asymptotic Born parameter approximation predicts markedly different scattering behavior for electrons and positrons. A striking feature is that functions pertaining to electron scattering are oscillatory in the scattering angle θ while the positron functions are not. In particular, the oscillations in the asymmetry parameter for electron scattering obtained numerically by Sherman are contained in the analytical approximate form. Also, the approach to the Rutherford cross-section is different from that quoted by Mott and Massey."

Weber, T. A.; Fradkin, D. M.; Hammer, C. L. 6870

A method of asymptotic expansion of Fourier-type integrals.

Ann. Physics **27** (1964), 362–376.

Authors' summary: "The expansion for large ν of integrals of the type $G(\nu) = \int_{t_1}^{t_2} e^{i\nu f(t)} g(t)\, dt$ is discussed. The method consists of using the mapping $z = f(t)$ so that the integral in question becomes $G(\nu) = \int_a^b e^{i\nu z} F(z)\, dz$. This integral is evaluated by distorting the path of integration into the complex plane in such a way that finite segments, emanating from endpoints or paralleling branch cuts, lie along paths characterized by $\mathrm{Im}(\nu z) = \text{constant}$. Integration over segments involving encircled singularities z_1 (or endpoints) with the minimum $\mathrm{Im}(\nu z_1)$ give the major contributions to the integral. The integral over such a segment is approximated in terms of an expansion with an accuracy depending on the magnitude of ν and the distance between the encircled singularity and the nearest neighboring singularity. A modification of this

procedure gives an accuracy dependent on the distance to the next nearest neighboring singularity. The first approach is applicable to widely separated singularities while the second approach is useful for two closely spaced singularities. As an illustrative example, the method is applied to an integral which arises in connection with Coulomb scattering in the preceding paper [#6869]."

Moskalenko, V. A. 6871

Criterion of superconductivity.

Dokl. Akad. Nauk SSSR **147** (1962), 1340–1343 (*Russian*); *translated as Soviet Physics Dokl.* **7** (1963), 1142–1145.

The normal state of a metal is investigated by using the Frohlich Hamiltonian for the electron-phonon interaction, and also by taking into account the shielded Coulomb interaction between the particles. The stability of the system against formation of bound pairs of electrons of opposite spins is investigated in the ladder approximation. A criterion, including the effect of the Coulomb interaction, is given for the occurrence of superconductivity.

A proof that the free energy of a spin system is extensive.

J. Mathematical Phys. **5** (1964), 1215–1222.

A spin system means here a system of particles each of which has a finite number of states. The author shows first that the free energy of such a system is a convex function of the Hamiltonian. This is used to study the thermodynamic properties of finite but large subsystems of infinite systems for which the Hamiltonian has the translational symmetry of a lattice on one, two, or three dimensions. The object is to show that the free energy and other derived properties (entropy, specific heat, etc.) are extensive, i.e., the free energy per particle has a limit as the size of the system becomes infinite. In three dimensions these limits are shown to exist if the interactions between pairs of points a distance r apart decrease faster than r^{-3}.

Snider, R. F. 6874

Perturbation variation methods for a quantum Boltzmann equation.

J. Mathematical Phys. **5** (1964), 1580–1587.

From the author's summary: "For molecules with degenerate internal states, the single-particle distribution function must be replaced, if the translational motion is treated classically, by a Wigner distribution-function density matrix. The modified Boltzmann integro-differential equation for this quantity has been previously derived but so far only limited solutions of the resulting equation have been obtained. Methods are herein discussed which enable the standard methods for the solution of the classical Boltzmann equation to be applied to the solution of this equation. Complications involving commutation properties are resolved."

Huang, Kerson 6876

Imperfect Bose gas.

Studies in Statistical Mechanics, Vol. II, pp. 1–106. *North-Holland, Amsterdam; Interscience, New York*, 1964.

The author gives a rather extensive and very systematic review of the present state of the problem. After an introduction dealing with the ideal Bose gas and some of the properties of liquid helium to be explained by the theory, and after a brief explanation of the cluster expansion and the pseudopotential method, the author goes over to the real problem. Two models of interactions are studied in great detail: the hard-sphere Bose gas, and a hard-sphere gas with a weak, simple, attractive part. In both cases the microscopic properties are derived. Among these the equation of state is discussed with particular emphasis on the condensation properties. The mathematical details are usually left out. Many of the topics appeared in the author's book [*Statistical mechanics*, Wiley, New York, 1963; MR **27** #4605], but are treated here more systematically.

Temperley, H. N. V. 6878

On Mayer's hypothesis about the critical region of a classical gas.

Proc. Phys. Soc. **83** (1964), 1013–1019.

Author's summary: "Mayer and Mayer suggested in 1940 that there might be two distinct temperatures that could be called critical, one defined as in the van der Waals theory, the other associated with a singularity in the virial series. The hypothesis is tested by applying the Percus-Yevick approximation proposed in 1958, which is now known to be fairly reliable at high densities, to a model of Gaussian type which allows crudely for the effects of both attractions and repulsions between molecules. The treatment shows that the hypothesis may be correct; the two temperatures are expected to be close together but need not be identical. In certain limiting cases one of them disappears."

The heat conductivity and viscosity of polyatomic gases.

Studies in Statistical Mechanics, Vol. II, pp. 241–268. *North-Holland, Amsterdam; Interscience, New York*, 1964.

This paper, written in the form of a report in 1954, is already considered as a classic among specialists, although it was never published formally. Its publication here therefore fills a gap and is well within the line of the "Studies in Statistical Mechanics" series.

The paper is essentially a rather straightforward extension of the well-known Chapman-Enskog method of kinetic theory of gases to the case of polyatomic molecules. The treatment is semi-classical, in the sense that translation is treated classically, whereas internal degrees of freedom are described by quantum numbers. (It does seem strange, however, that the effect of the internal degrees of freedom is not retained in the flow term of the generalized Boltzmann equation.) Heat conductivity, viscosity, and volume viscosity are calculated in detail.

Barrett, E. B.; Whitmer, R. F.; Tetenbaum, S. J. 6882

Nonlinear interaction of an electromagnetic wave with a plasma layer in the presence of a static magnetic field. III. Theory of mixing.

Phys. Rev. (2) **135** (1964), A369–A373.

Two monochromatic plane waves of angular frequencies ω_1, ω_2 are incident normally on a plasma layer of uniform density in a uniform magnetic field perpendicular to the direction of propagation. The electric field of each incident wave is linearly polarized in a direction perpendicular to the magnetic field. The motion of the positive ions and thermal effects are neglected and a constant electron-neutral-particle collision frequency is assumed. The novel feature of the present investigation is that the amplitudes of the two incident waves are of comparable magnitude.

Following the methods of Parts I and II by R. F. Whitmer and E. B. Barrett [same Rev. (2) **121** (1961), 661–668; MR **22** #9014; ibid. (2) **125** (1962), 1478–1484; MR **25** #1784], double Fourier series expansions in terms of multiples of ω_1 and ω_2 are substituted into the nonlinear set consisting of the first two velocity moments of Boltzmann's equation, and Maxwell's equations. The first-order approximation is carried out to give the amplitudes of the various components having frequencies $\pm\omega_1$, $\pm\omega_2$. These results are compared with the second-harmonic waves of Part I. First, it is found that the forward and backward waves are coupled, whereas they cancelled to the first order in Part I; secondly, the power at the sum and difference frequencies is proportional to the product of the input powers of the incident waves.

The results of computer calculations of transmitted and reflected powers for the sum and difference frequencies are presented graphically. These show quite sharp resonances at expected values of the magnetic field in terms of the electron density. This provides a means of determining the electron density in the plasma layer from measurements of resonant magnetic-field strength.

Tetenbaum, S. J.; Whitmer, R. F.; Barrett, E. B. 6883

Nonlinear interaction of an electromagnetic wave with a plasma layer in the presence of a static magnetic field. IV. Experimental results.

Phys. Rev. (2) **135** (1964), A374–A381.

Authors' summary: "The nonlinear interaction of an electromagnetic wave with a uniform, weakly ionized

anisotropic plasma layer has been investigated experimentally. The experiment was designed to comply as closely as possible with the assumptions used in the theory of the nonlinear interaction, which is given in Parts I, II, and III [see #6882 above] of this series of papers. Experimental results on sum and difference frequency mixing and harmonic generation are described as a function of the ambient electron density, the electron-neutral-particle collision frequency, the external dc magnetic-field strength, thickness of the plasma layer, and the field strengths and frequencies of the incident waves. The case of linearly polarized small-amplitude microwave signals incident on a layer of helium plasma is examined. Within the plasma, the signals propagate as plane waves with their directions of propagation and polarization normal to the dc magnetic field (i.e., the extraordinary mode of propagation). A detailed comparison is made between the experimental results and the theoretical predictions. Quantitative agreement was obtained over the electron density range permitted by the experiment. The results show that the plasma model assumed in the theory is an accurate representation of the actual plasma, and that the small-signal analysis accurately predicts the effects of the nonlinear terms in the Boltzmann equation on propagation phenomena. However, special care is required to insure that the plane-wave, infinite-medium assumption employed in the theory is satisfied experimentally. The experimental results also establish the validity of using certain characteristics of the nonlinear phenomena as a tool for measuring the electron density in a plasma as proposed in Parts II and III. A resonance was detected in the sum frequency wave which is not predicted by the theory. This resonance occurs for values of the dc magnetic-field strength corresponding to cyclotron resonance at the arithmetic mean of the two incident frequencies. The origin of this resonance is not understood at this time."

Nuova determinazione della fotoionizzazione a monte di un'onda d'urto intensa.

Atti Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. Natur. (8) 35 (1963), 417–424.

The paper is concerned with the ionisation produced upstream from a plane shock wave of great intensity. The gas upstream from the wave-front is sufficiently rarefied that recombination effects, due to collisions, can be neglected in comparision with those due to radiation. The radiation temperature in this region is assumed to be much greater than the gas temperature so that the ionisation due to collisions can also be neglected. It is also assumed for the upstream region that the density, the pressure, the gas temperature, and the fluid velocity relative to the wave front are all constant. Under these conditions a first integral of the radiant energy equation is derived. The variation of the radiation temperature with the degree of ionisation is considered and illustrated graphically in the case of argon. The directional dependence of the radiation intensity is also investigated.

Mosburg, E. R., Jr.; Persson, K.-B. 6888

Nonlinear ambipolar diffusion of an isothermal plasma across a magnetic field.

Phys. Fluids 7 (1964), 1829–1833.

Authors' summary: "Solutions are presented of the first two moment equations, including nonlinear terms, for the ambipolar diffusion of an isothermal plasma across a magnetic field. The two geometries considered are the plane parallel case and the infinite cylinder with axial symmetry. The Bohm criterion is automatically satisfied by the solutions. It is shown that the singularity in the space derivative of the ambipolar drift velocity at the plasma boundary cannot be removed by an axial magnetic field of any strength. Thus the plasma drift velocity and the plasma density remain monotonic functions of the position coordinate. It is also shown, under the assumptions of this theory, that the ambipolar space charge field is always directed outward and does not reverse direction in this isothermal approximation even for extremely high magnetic fields. One is forced to conclude that a realistic theory of ambipolar diffusion requires the consideration of thermal gradients within the plasma."

Peleya, Roger F. 6889

Bivariate distribution function for a plasma in a magnetic field.

Phys. Fluids 7 (1964), 1719–1720.

The position-velocity distribution function for the Brownian motion of a plasma in a magnetic field is given. Diffusion coefficients across and along the magnetic field are then given. *E. Pinney* (Berkeley, Calif.)

Trilling, Leon 6890

Asymptotic solution of the Boltzmann-Krook equation for the Rayleigh shear flow problem.

Phys. Fluids 7 (1964), 1681–1691.

This paper shows that the similar solution of the compressible Rayleigh flow problem, namely, an impulsive start of an infinite plate, can be obtained as a zero approximation from the BGK model equation. The problem was analysed previously from the continuum point of view in the references given in this paper. The present author uses Hilbert's expansion scheme to construct an asymptotic solution in the limit of small Knudsen's number. In order to produce a non-trivial zero-order solution, as well as to take into account the viscous effect properly, the coordinate and velocity perpendicular to the plate are stretched as in the ordinary boundary-layer theory. The expansion parameter, which is dictated by the boundary-layer theory, is found to be the square root of the Knudsen number (or the inverse of the square root of the Reynolds number by assuming that the Mach number is of the order unity). The zero-order equation is set to satisfy the non-slip fluid mechanical boundary conditions. As a consequence of Hilbert's procedure (in contrast to the Enskog-Chapman procedure) the differential order of the higher-order approximate equations does not increase. The author suggests slip boundary conditions to be used for the higher-order approximate equations. The boundary conditions on the detailed distribution function itself instead of the fluid mechanical quantities such as density, drift, temperature are briefly discussed at the end of the paper.

Viskanta, Raymond 6891

Some considerations of radiation in magnetohydrodynamic Couette flow. (German summary)

Z. Angew. Math. Phys. 15 (1964), 227–236.

The flow between two relatively moving plane walls under the influence of a constant pressure gradient, of an electrically conducting, radiating, viscous, incompressible fluid is considered, in the presence of an external magnetic field of constant strength acting in a direction perpendicular to the walls. The effect of magnetic field on energy transfer when radiation is also present is studied (1) when the electric field E is negligible, and (2) when E is not negligible. The energy equation is solved numerically for different types of wall conditions.

S. D. Nigam (Madras)

Weitzner, Harold 6892

Plasma oscillations and Landau damping.

Phys. Fluids 6 (1963), 1123–1127.

This paper considers the problem of plane wave oscillations of a plasma in an attempt to clarify some points concerned with the existence of such oscillations and the associated mechanism of Landau damping. Following Landau's treatment [Acad. Sci. USSR J. Phys. 10 (1946), 25–34; MR 8, 401] the author uses the linearized Vlasov and Poisson equations to obtain an integral representation for the electric field for the case of a plane wave oscillation. Two classes of distribution functions are considered. The first consists of those functions which do not vanish for any particle speed and whose first derivatives vanish at only a limited number of points. The second consists of functions which vanish identically for particle speed greater than some constant. It is shown that for stable distributions of the first class, which includes Maxwellians, the electric field damps not exponentially but as some inverse power of time. For stable distributions of the second class, and for wavenumbers less than a certain constant, the plasma oscillations do have an undamped component corresponding to a conventional normal mode with a phase speed greater than the fastest particle speed. For wavenumbers larger than that constant the oscillations again tend to zero as some inverse power of time.

Levelt, J. M. H.; Cohen, E. G. D. 6893

A critical study of some theories of the liquid state including a comparison with experiment.

Studies in Statistical Mechanics, Vol. II, pp. 107–239. *North-Holland, Amsterdam; Interscience, New York,* 1964.

This is, in the reviewer's opinion, the best available review paper on liquid state theory. With perfect clarity and simplicity, the authors expose the main theories proposed up to now (they do not claim completeness), as well as all improvements on these theories; at the end of each chapter the crucial experimental evidence is discussed.

After an introduction devoted to the virial expansion and its application to dense gases, the cell model is very extensively discussed. Although quite simple in principle, this model is still probably the one which gives the best results when compared to experiment. All attempts at complicating it have given either meager partial improvements, or have even worsened the agreement with experiment. The hole theories have not been more successful. The cell-cluster theory, although correcting the main drawback of the cell model, i.e., the lack of correlations between molecules, has also led to disappointing results, because of bad convergence: small cell-clusters are insufficient to improve significantly the theory. The two main difficulties of the cell model (and indeed of any existing model) of liquids therefore remain unsolved: the explanation of a large lack in entropy and the understanding of the nature of molecular correlations.

The reading of this masterful paper is strongly recommended, not only to specialists, but to anyone interested in the present state of this great unsolved problem in physics.

Morita, Tohru 6894

Statistical mechanics of quenched solid solutions with application to magnetically dilute alloys.

J. Mathematical Phys. 5 (1964), 1401–1405.

The atoms in quenched solid solutions and alloys are usually frozen in a metastable configuration. In theories of the properties of internal degrees of freedom of such systems, assumptions are made, either explicitly or implicitly, concerning the spatial arrangement of the component atoms. In this paper the properties of a metastable system are treated in terms of a suitably defined

fictitious equilibrium system. The formalism is applied to the case of a magnetically dilute alloy. The result for the magnetization is the same as that obtained by Brout [Phys. Rev. (2) **115** (1959), 824–835]. Application of the formalism to less dilute systems is promised.

Birkhoff, G. 6895
Reactor criticality in neutron transport theory.
Rend. Mat. e Appl. (5) **22** (1963), 102–126.
The author continues his investigations [Proc. Nat. Acad. Sci. U.S.A. **45** (1959), 567–569; MR **21** #3131] into the nature of reactor criticality in neutron transport theory. In the related topic of reactor criticality with multigroup diffusion models, the theory of positive operators (e.g., Jentsch's Theorem and the Krein-Rutman Theorem) has been a very effective tool in obtaining theoretical results [G. Habetler and M. Martino, Proc. Sympos. Appl. Math., Vol. XI, pp. 127–139, Amer. Math. Soc., Providence, R.I., 1961; MR **26** #2280]. To obtain the proper setting, the author generalizes these results to the case of a bounded operator on a Banach lattice, one of whose powers is uniformly positive (Theorem 2, p. 118), and then applies this generalization to the transport theory case of monoenergetic neutrons and isotropic scattering in a homogeneous bare reactor. Extensions to inhomogeneous reactors and nonisotropic scattering are also considered.

Exact and asymptotic solution of the energy-dependent Boltzmann equation in the study of the neutron slowing down.
Ann. Physics **27** (1964), 283–296.
Authors' summary: "In this paper we obtain the exact and asymptotic solution of the Boltzmann equation which governs the stationary energy distribution of neutrons slowing down in an infinite homogeneous medium in the case of a general capture law. Specific results are given for particular cases of variation of the cross sections versus the neutron velocity."
G. M. Wing (Boulder, Colo.)

Boffi, V. C. 6897
Exact and asymptotic time-energy distribution of neutrons slowing down in an infinite homogeneous medium.
Ann. Physics **27** (1964), 297–330.
Author's summary: "In this paper a new method for integrating the time-energy dependent Boltzmann equation for neutrons slowing down in an infinite homogeneous medium is presented. The exact step-by-step energy distribution at the time t is constructed. The behavior of the exact distribution for small values of energy and then for large values of time is derived as the limit of the sequence of the continuous functions, which step-by-step represent the physical solution of the problem. Information on the behavior for large and small values of time of the exact step-by-step time-energy distribution is also given. How the absorption can be accounted for is finally mentioned."
G. M. Wing (Boulder, Colo.)

Depken, S. 6898
Remark to the solution of the neutron transport equation. (Italian summary)
Nuovo Cimento (10) **31** (1964), 7–9.
The author derives a closed-form infinite-medium solution to the multi-energy transport equation, but a solution valid under rather restrictive conditions. The medium contains a point mono-energetic and isotropic source. Scattering is assumed isotropic in the center of mass and the ratio of the scattering cross-section of each element to the total cross-section in the medium is taken to be energy-dependent.

The author introduces Fourier, Legendre, and Mellin transforms (apparently the Mellin transform is mistakenly referred to as a Laplace transform) which eliminate, successively, the spatial, angular and energy variables. The transformed Boltzmann equation is solved, and inversion of the transformed solution yields all Legendre components of the flux. However, these components are given by integrals which are extremely complicated, and it is not clear that the author's method is practical.

The paper is very compact and somewhat hard to follow. It seems to be a summary of work described more fully in the reference he cites.

One-speed neutron transport in two adjacent half-spaces.
J. Mathematical Phys. **5** (1964), 668–674.
Authors' summary: "Using Case's method for solving the one-speed transport equation with isotropic scattering, the Milne problem solution, the solution for a constant source in one half-space, and the Green's function solution are obtained for two adjacent half-spaces. These problems have been solved previously by other methods. Here the derivations are greatly simplified by using Case's method."
E. M. Gelbard (Pittsburgh, Pa.)

RELATIVITY

Bialas, Andrzej 6901
Equations of motion of a rotating particle with magnetic moment.
Acta Phys. Polon. **22** (1962), 499–510.
Continuing a previous paper [same Acta **20** (1961), 831–844; MR **27** #3250], the author's thesis is as follows.

Charged point particles with spin satisfy the force equation $\dot{P}^\alpha = X^\alpha$ and the torque equation $\dot{\Omega}^{\alpha\beta} + P^\alpha u^\beta - P^\beta u^\alpha = -2X^{[\alpha\beta]}$, with $\Omega^{\alpha\beta} u_\beta = 0$. Starting from the work of Mathisson [ibid. 6 (1937), 163–200; Proc. Cambridge Philos. Soc. 36 (1940), 331–350; MR 2, 207; ibid. 38 (1942), 40–60; MR 3, 158], the author shows that his equations for particles with spin $\Omega^{\alpha\beta}$, charge, and magnetic moment can indeed be put into this form. To this end one must define P^α such that it is no longer parallel to the velocity u^α, but it is argued that this is physically reasonable. *F. Rohrlich* (Syracuse, N.Y.)

Bondi, H. 6902

The contraction of gravitating spheres.

Proc. Roy. Soc. Ser. A **281** (1964), 39–48.

In this important paper, written in the author's usual lucid style, it is first argued that the association between the nucleon number within a gravitating sphere S and the integral of the trace of the energy-momentum tensor, extended over S, is fallacious. The field equations for the contraction of S are written down and physically interpreted, the coordinates used being of the Schwarzschild type. The slow contraction of a completely opaque sphere is considered. In particular, a family of spheres generically described by the Schwarzschild interior solution is investigated, and after obtaining the particle paths it is shown that the simple $\frac{5}{3}$ power law which obtains in Newtonian theory for the pressure-density relation has to be replaced by a steeper dependence of pressure on density for high gravitational potentials. Finally, using radiation coordinates previously introduced by Bondi, van der Burg and Metzner [same Proc. **269** (1962), 21–52; MR **26** #4793], radiating contracting systems are examined, a full set of equations relating to these having been written down. A particular example derived from the Schwarzschild model is discussed.

H. A. Buchdahl (Canberra)

Bondi, H. 6903

Massive spheres in general relativity.

Proc. Roy. Soc. Ser. A **282** (1964), 303–317.

Author's summary: "The exact relativistic form of the equation of hydrostatic support by an isotropic pressure is found in an especially convenient form. A quantity u, the natural generalization of Schwarzschild's m/r ratio at the surface, is used, and it is proved that the critical value $u = \frac{1}{2}$ cannot be attained except perhaps under conditions of severe tension. It is shown that if u is everywhere less than $\frac{1}{2}$, different physical restrictions are significant in well-defined inner and outer zones as far as the attainment of high u values is concerned. A number of limiting configurations are derived for physically significant restrictions. In particular it is shown that if the density is nowhere negative, then $u < 0.485\ldots$, while if in addition the density is nowhere less than three times the pressure and nowhere increasing outwards, then $u \lesssim 0.319$."

Bonazzola, Silvano 6904

Sur le tenseur énergie-impulsion approché de Taub.

C. R. Acad. Sci. Paris **259** (1964), 2605–2608.

The author uses the approximate stress-energy tensor proposed by the reviewer [J. Mathematical Phys. **2** (1961), 787–793] to calculate the exact material plus gravitational energy for a spherically symmetric time-dependent space-time whose metric tensor satisfies certain boundary conditions at spatial infinity ($r \to \infty$). These conditions insure that the metric approaches that of Minkowski space as $r \to \infty$ and hence insure that the exact expression for the total energy is approximated by the approximate one as $r \to \infty$.

Braunss, G. 6905

Zur Schwarzschildschen Lösung in einer einheitlichen Feldtheorie. (English summary)

Z. Naturforsch. **19a** (1964), 1032–1033.

In an earlier paper [same Z. **19a** (1964), 401–405; MR **29** #1990] the author introduced the hypothesis that the components of the metric tensor of space-time are functionals of a "world-field" which was, for the sake of simplicity, taken to be a scalar Φ. The Einstein tensor is thus equated to a functional of Φ and its derivatives, chosen in such a way that the Bianchi identities give a non-linear Klein-Gordon equation for Φ. This Ansatz in the first place involves an arbitrarily disposable function $F(\Phi)$. In this paper it is shown that even if one imposes the condition that space-time be flat when $\Phi = 0$, a certain choice of F will, in the static spherically symmetric case, lead to a Schwarzschild field to within terms $O(r^{-2})$. Finally the question of determining particle trajectories is briefly discussed. *H. A. Buchdahl* (Canberra)

Bruhat, Y. [Fourès-Bruhat, Yvonne] 6906

Sur la théorie des propagateurs.

Ann. Mat. Pura Appl. (4) **64** (1964), 191–228.

Starting with the concept of tensor propagators, introduced by Lichnerowicz, the author has shown that the propagator is the sum of a measure carried by the characteristic cone and of a usual function having support inside the cone. This function is given in the form of a convergent series of functions, in which each term is given by an integral relation of its predecessor. Next, the asymptotic properties of this function have been studied for uniformly hyperbolic metric, and, with a further hypothesis tantamount to the asymptotic Minkowskian behaviour of the metric, the function tends to zero on all lines which are uniformly temporal and is summable on such lines. The result is applied to retarded electromagnetic potential of a charged particle. A further example is furnished by determining the scalar and vector propagators for the de Sitter space-time. *N. D. SenGupta* (Bombay)

Dehnen, H. 6907a

Über den Energietensor des Gravitationsfeldes.

Z. Physik **179** (1964), 76–95.

Dehnen, H. 6907b

Über den Energieinhalt statischer Gravitationsfelder nach der allgemeinen Relativitätstheorie in Newtonscher Näherung.

Z. Physik **179** (1964), 96–101.

In the first paper, the author defines the energy-momentum density of the gravitational field relative to an

arbitrarily chosen congruence of observers [cf. the reviewer, Les théories relativistes de la gravitation (Royaumont, 1959), pp. 85–91, Éditions Centre Nat. Recherche Sci., Paris, 1962; MR 29 #2036]. Exploiting analogies between this formalism and electromagnetic theory, he constructs also an energy-momentum "tensor" for the gravitational field. He treats the Schwarzschild field as an example, choosing a congruence of observers adapted to the time-like isometry.

In the second paper, he shows, with the same choice of observers, that in a weak field approximation his expression for the total field energy of a static system agrees with the Newtonian result.

Fonctions de Green dans un espace de Riemann: Méthode de calcul pour les champs faibles; expression explicite, à l'ordre G, pour un champ statique à symétrie sphérique.

C. R. Acad. Sci. Paris **256** (1963), 3827–3829.

This paper calculates the first-order "tail" term or single scattering introduced into the Green's function for the vector wave equation, $g^{ab}A_{c;ab}+R_c{}^dA_d=0$, by a weak gravitational field. It is shown that in a linearised Schwarzschild metric this term is zero for the Green's function between two points of space-time, x, x', if there is insufficient time for a signal leaving one to reach the origin of the Schwarzschild field and return to the other.

S. W. Hawking (Cambridge, England)

Edelen, Dominic G. B. 6909

Circulation in relativistic continuum mechanics.

J. Math. Anal. Appl. **9** (1964), 331–335.

In this paper the author discusses a class of integrals formed from quantities that describe the behavior of material regions of space-time. The author generalizes the discussion given by the reviewer [Arch. Rational Mech. Anal. **3** (1959), 312–324; MR **21** #4732] to stress-energy tensors which may differ from those describing a perfect fluid. The author falsely claims that previous discussions have been based on a rotation tensor that is physically questionable. In the reviewer's paper the notion of rotation is described in terms of a vector in space-time whose vanishing is almost but not quite equivalent to the vanishing of the author's "Fermi rotation tensor".

Joshi, R. L.; Husain, S. I. 6911

Total radiation in Einstein's unified field theory.

Tensor (N.S.) **15** (1964), 66–73.

The state of total radiation is said to exist at a given point of a differentiable manifold V_4 of class $(C^2, C^4 \text{ pm})$ if there exists a null vector l such that

$$l_\nu R^\alpha_{\beta,\lambda\mu}+l_\lambda R^\alpha_{\beta,\mu\nu}+l_\mu R^\alpha_{\beta,\nu\lambda}=0,$$

$$l_\alpha R^\alpha_{\beta,\lambda\mu}=l_\beta R_{\lambda\mu}, \qquad l_\alpha R^\alpha_{\beta,\lambda\mu}l^\lambda=0.$$

The authors verify that these conditions can be satisfied everywhere in the case of the wave solutions of Einstein's field equations obtained by Takeno [Tensor (N.S.) **6** (1956), 69–83; MR **19**, 226; ibid. (N.S.) **7** (1957), 143–172; MR **20** #3888; ibid. (N.S.) **8** (1958), 21–37; MR **20** #3888], Hlavatý [*Geometry of Einstein's unified field theory*, Noordhoff, Groningen, 1957; MR **20** #5067] and Vaidya [Progr. Theoret. Phys. **25** (1961), 305–314; MR **22** #10735]. It is found that for a cylindrically symmetric case, the radiation condition can only be satisfied asymptotically as $1/r^2 \to 0$.

Schmutzer, Ernst 6914

Spinorielle Feldtheorien und Noether-Theorem in der gekrümmten Raum-Zeit. (English summary)

Z. Naturforsch. **19a** (1964), 1027–1031.

This paper represents a continuation of the author's recent investigations concerning spinorial field theories [same Z. **15a** (1960), 355–362; MR **22** #603; ibid. **17a** (1962), 707–711; MR **27** #4182]. It is emphasized that of the two points of view that can, as was pointed out by Sommerfeld, be adopted towards spinors in general, the one according to which spinors are treated as invariants with respect to coordinate transformations possesses certain advantages, particularly when a transition to curvilinear coordinates is sought. The alternative method, which is the one which had in fact been generally followed, supposedly fails in this regard. Against the background of 4-dimensional Riemannian space-time a Noether-type theorem is deduced, the fundamental metrical quantities in the latter being the metrical spin tensor and not the usual metric tensor. This procedure rules out the use of the Belinfante tensor, but the method yields the well-known energy-momentum tensor and the correct spin integral. These results are applied to a system consisting

of combined gravitational, electromagnetic and spinor fields with special—but very brief—reference to the theories of Dirac and Heisenberg. *H. Bondi* (Pretoria)

Taub, A. H. 6915

Hydrodynamics and general relativity.

Fundamental Topics in Relativistic Fluid Mechanics and Magnetohydrodynamics (*Proc. Sympos., Michigan State Univ.*, 1962), *pp.* 21–28. *Academic Press, New York,* 1963.

The author discusses the following four topics in relativistic hydrodynamics: (1) a variational principle, and the formulation of the Einstein field equations and conservation of the stress-energy tensor from this principle; (2) the various conservation laws of relativistic fluids, their independence of the variational principle, and their interdependence for compressible non-charged fluids; (3) the "velocity potential" for isentropic irrotational relativistic fluids and the velocity four-vector U^a for such flows; (4) remarks on the intrinsic nature of discontinuities of the metric tensor. In the first topic, the author notes that the theory of relativistic fluids is concerned with a degenerate variational principle. Further, the type of variational principle used leads to no additional equations. Thus, the expressions for the characteristic values and directions of the symmetric stress-energy tensor; the relation between specific internal energy, rest density, and pressure; and the condition for isentropic flow are all independent of the variational principle and are new assumptions. However, the conservation of mass implies conservation of entropy. By studying the vorticity tensor, it is noted that for irrotational isentropic flows, U^a can be expressed in terms of the metric tensor of a special coordinate system. Hence, discontinuities in U^a (such as those due to shocks) are reflected in discontinuities of the metric tensor.

On a method of solving the equations of Newton and Einstein in celestial mechanics. (Bulgarian. Russian and English summaries)

Bălgar. Akad. Nauk. Otd. Mat. Fiz. Nauk. Izv. Fiz. Inst. s Aneb **12** (1964), 191–204.

Author's summary: "The variables of Newton's and Einstein's celestial mechanics are developed in power series with respect to the constant of the gravitational interaction (Newton's gravitational constant). Comparatively simple analytic developments are obtained which in certain cases, as for example in the problem of [illegible] bodies of Newton's universal mechanics, can lead to simple quadratures. The convergence of the new method is verified by the problem of two bodies in Newton's celestial mechanics. The calculations show that in this case even the first members of the power series given by us converge rather quickly to Kepler's ellipses, parabolas and hyperbolas.

"The novel feature in our approximate solution of the problem of n bodies within the framework of Newton's celestial mechanics is that it gives, through elementary time functions and the initial conditions of movement, the explicit movement of n bodies. Furthermore, no suppositions are made with respect to the mass of the bodies. As is well known, almost all approximate solutions of the problem of n bodies make use of the supposition that in the system there exists a central body with a mass considerably exceeding the masses of the rest of the bodies. We do not use this hypothesis, and on that account our method can also be applied to such problems as a movement of a body (with comparatively small mass) in the gravitational field of a double, triple or quadruple star. Such problems are difficult to treat by means of classical celestial mechanics.

"It is easy to show that our integrals satisfy the conservation law of the system's momentum and the movement of the system's center of gravity."

Zur Theorie der nahezu kommensurablen Bewegung der Planetoiden des Hestia-Typus im Raum.

Bayer. Akad. Wiss. Math.-Natur. Kl. S.-B. **1963**, *Abt. II*, 129–153 (1964).

The problem treated is that of the motion perpendicular to Jupiter's orbital plane of an asteroid in the vicinity of a commensurability with Jupiter. The eccentricities of the orbits of both Jupiter and the asteroid are ignored. Next, the short-period terms are ignored and the equations of the variations of the elements are reduced to two equations of the first order with i, the inclination, and ζ, a long-period or critical argument, as dependent variables. The author treats these equations by using i as independent variable, eliminating the time.

{The solution of the problem, which may be reduced to that of a Hamiltonian system with one degree of freedom, is well known. In general, i will be a periodic function of the time with finite period. (The exceptional case is that of the limitational type of motion in which the period becomes infinite.) The variable i is therefore unsuitable as independent variable, and nearly all of the results of the papers are invalid.}

Alcune considerazioni sul problema dei tre corpi.

Atti Accad. Sci. Torino Cl. Sci. Fis. Mat. Natur. **98** (1963/64), 355–365.

J. Meffroy [C. R. Acad. Sci. Paris **254** (1962), 818–820; MR **24** #B1200] pointed out the possibility of a new particular solution of the three-body problem in which the plane of the three bodies rolls along a cone of revolution with fixed axis and vertex at one of the bodies considered as the central body. The author shows that in general such a solution cannot exist provided that the case in which the plane of the three bodies is of fixed direction be excepted. *E. Leimanis* (Vancouver, B.C.)

Lebrun, C.; Robe, H. 6923

Note sur une extension du problème restreint des 3 corps.

Acad. Roy. Belg. Bull. Cl. Sci. (5) **50** (1964), 315–327.

The authors locate the singular points (Lagrangian or libration points) of the potential function representing a modified form of the restricted problem of three bodies in rotating coordinates. The problem involves, besides the conventional infinitesimal particle, two ellipsoids as the primaries which revolve in circular orbits forming a system which might represent a close binary configuration. Formulation includes the second Legendre polynomial but no higher. Results show that the triangular libration points might be stable and the collinear points are always unstable—in agreement with the situation occurring in the conventional restricted problem, i.e., when the primaries are point masses.

Derman, Cyrus 6930

On sequential decisions and Markov chains.

Management Sci. **9** (1962/63), 16–24.

A system with several states passes from state to state according to probability laws determined by making one of K decisions; a cost is incurred each time a decision is made. Thus if at time t the system is in state i and the decision k is made, then the probability of passing to state j is $q_{ij}(k)$, and the cost $w_{ik} \geq 0$ is incurred. The author considers the problem of minimizing the limit superior as $t \to \infty$ of the average cost up to time t, and shows that this problem has a solution in stationary pure strategies, i.e., strategies in which the choice of the decision k depends only on the current state i and the dependence is non-probabilistic. Another problem considered is that of minimizing total (unaveraged) cost, and a similar conclusion is reached. It is shown that the problems of finding optimal strategies in the two cases are equivalent to certain linear programming problems.

The existence of an optimal stationary pure strategy for the first problem is a special case of Theorem 2 of Gillette [*Contributions to the theory of games*, Vol. 3, pp. 179–187, Princeton Univ. Press, Princeton, N.J., 1957; MR **19**, 1147] on stochastic 2-person games. The second problem is related to work of Shapley [Proc. Nat. Acad. Sci. U.S.A. **39** (1953), 1095–1100; MR **15**, 887], also on stochastic 2-person games.

Leonov, V. V. 6931

A dynamic programming problem for multi-stage processes. (Russian)

Diskret. Analiz. No. 2 (1964), 48–55.

Consider the N-stage process defined by the recurrence relation $m_i = f(k_i, l_i, m_{i-1})$ $(i = 1, 2, \cdots, N)$, where the integer m_i denotes the state, $k_i \in \{1, 2, \cdots, K\} = Q_1$ and $l_i \in \{1, 2, \cdots, L\} = Q_2$ are the controls at stage i. Let $S_N^{k_1, \cdots, k_N}(m_0)$ be the set of all possible terminal states for the initial state m_0 and controls $k_1, \cdots, k_N$. The author is interested in the following problem: Find $(k_1, l_1), \cdots, (k_N, l_N)$ such that

$$R(m_N) = \max_{(k_1, \cdots, k_N) \in Q_1^N} \min_{m \in S_N^{k_1, \cdots, k_N}(m_0)} R(m),$$

where $R(m)$ is monotone increasing in m. From the author's introduction: "The purpose of this paper is to clarify such properties of the multistage process which will permit one, in many instances, to considerably reduce the number of checks when searching for an optimal control process."

Varsavsky, Oscar 6932

Relations triples dans les programmes linéaires généralisés.

C. R. Acad. Sci. Paris **259** (1964), 2585–2588.

Given the linear programming problem: max FE $= xc$, subject to (1) $Ax \leq b$, (2) $x \geq 0$, and given the vectors b and c, which matrix $\bar{A}$ and corresponding vector $\bar{x}$ will maximize the function FE so that $\bar{x}c \geq xc$ for all solutions x of (A, b, c)! This is no longer a linear problem.

The author restricts himself to the case where $\bar{A} \in \mathfrak{A}$, the set $\mathfrak{A}$ itself being defined by linear constraints. The coefficients a_{ij} have then to satisfy the conditions:

$$\text{(3)} \qquad \sum_{i,j} \alpha_{kij} a_{ij} \geq \beta_k \qquad (k = 1, 2, \cdots, r),$$

where the α_{kij} and β_k are known.

Let y, t, z be the Lagrange multipliers associated with (1), (2), (3), respectively. It is then shown that at the maximum value of FE the following three equalities hold:

$$\sum_j c_j x_j = \sum_i y_i b_i = \sum_k z_k \beta_k.$$

From this it is concluded that the constraints (3) on the coefficients a_{ij} are affected by the "prices" z just like the "resources" b in the usual economic interpretation. That is to say that, apart from possible discontinuities, the z_k measure $\partial \text{FE}/\partial \beta_k$. Or, to put it still in another way, the z measure the "scarcity" of the β. In addition, it can be shown that $\sum_k z_k \alpha_{kij} = y_i x_j \geq 0$. Variations in the "resources"

b instead of in the elements of A lead to a similar problem: max FE $= xc$ subject to $Ax \leq b$, $x \geq 0$, and the linear constraint

$$(4) \qquad \sum \alpha_{ki} b_i \leq \gamma_k \qquad (k = 1, 2, \cdots, r).$$

If t_k are the Lagrange multipliers associated with the constraints (4), the analogous result is that at the maximum value of FE one has the "triality":

$$\sum_j c_j x_j = \sum_i b_i y_i = \sum_k \gamma_k t_k,$$

as well as the equality

$$\sum_k t_k \alpha_{ki} = y_i \qquad (i = 1, 2, \cdots, m).$$

Similarly, if the "costs" c are permitted to vary subject to the conditions:

$$(5) \qquad \sum_j \alpha_{kj}' c_j \leq \gamma_k'$$

and the t_k' are the Lagrange multipliers associated with the constraints (5), the result is that at the maximum value of FE the "triality" holds: $\sum_j c_j x_j = \sum_i b_i y_i = \sum_k \gamma_k' t_k'$, as well as the equality $\sum_k t_k' \alpha_{kj}' = x_j$ ($j = 1, 2, \cdots, n$). Finally, if the elements a_{ij}, the resources b_i and the costs c_j are allowed to vary simultaneously and independently of each other, the result is that the following five equalities hold:

$$\mathrm{FE} = \sum_j c_j x_j = \sum_i b_i y_i = \sum_k z_k \beta_k = \sum_k t_k' \gamma_k' = \sum_k t_k \gamma_k.$$

Verbovskiĭ, B. S. 6934

The existence of a solution to a many-index problem in linear programming. (Russian)

Dokl. Akad. Nauk SSSR **158** (1964), 763–766.

Solvability conditions are established for the following "many-index" linear program: Minimize

$$L = \sum_{k \in M} p_{i_1 \cdots i_s} x_{i_1 \cdots i_s},$$

the variables being subject to the restrictions

$$\sum_{k \in M_j} a^{(j)}_{i_1 \cdots i_s} x_{i_1 \cdots i_s} \leq b_{M_j(i_1 \cdots i_s)},$$

$$= b_{M_j(i_1 \cdots i_s)};$$

$x_{i_1 \cdots i_s} \geq 0$; $j = 1, \cdots, l$; $i_k = 1, \cdots, n_k$; $k = 1, \cdots, s$. Here $a^{(j)}_{i_1 \cdots i_s}$, $p_{i_1 \cdots i_s}$ are given real numbers, the $b_{M_j(i_1 \cdots i_s)}$'s are given non-negative numbers.

de Cani, John S. 6935

A dynamic programming algorithm for embedded Markov chains when the planning horizon is at infinity.

Management Sci. **10** (1963/64), 716–733.

R. A. Howard's policy-space approximation technique of dynamic programming over a Markov chain [*Dynamic programming and Markov processes*, Technology Press of M.I.T., Cambridge, Mass., 1960; MR **22** #9287] is extended to Markov renewal processes with a finite number of states (in addition to the Markovian transitions, the times between successive transitions from state i to state j are non-negative, independent and identically distributed random variables whose distribution depends upon i and j). A return function linear in time, with a fixed return at the end of the transition interval, is assumed. For each state i a choice of a policy from among k_i possible policies determines the return functions, the transition probabilities, and the expected intertransitions times corresponding to that particular state only.

Two models with infinite planning horizon are studied and algorithms for determining the optimal policies, which reduce to Howard's for common cases, are given and their convergence to optimal policies is proved. In the first model the time rate of return is taken as objective function and both ergodic and non-ergodic chains are dealt with. Two numerical examples illustrate the algorithm. In the second model with continuous discounting, the present value of the expected return from the process is maximized. The illustrative numerical example is as elaborate and suggestive as the other two.

The author points out that W. S. Jewel [Operations Res. **11** (1963), 938–948; MR **29** #677; ibid. **11** (1963), 949–971; MR **29** #678] has independently developed dynamic programming algorithms similar to those contained in the reviewed paper.

B. Bereanu (Bucharest)

Balaş, E.; Ivănescu, P. [Ivănescu, Petru L.] 6936

On the transportation problem. II.

Cahiers Centre Études Recherche Opér. **4** (1962), 131–160.

The first four chapters were reviewed earlier [E. Balaş and P. Ivănescu, same Cahiers **4** (1962), 98–116; MR **26** #7447; E. Balaş and L. P. Hammer, Acad. R. P. Romîne Stud. Cerc. Mat. **11** (1960), 439–450; MR **27** #1305; E. Balaş and P. Ivănescu, ibid. **12** (1961), 413–427; MR **27** #1306; ibid. **12** (1961), 429–435; MR **27** #1307; E. Balaş and L. P. Hammer, Com. Acad. R. P. Romîne **11** (1961), 1047–1049; MR **27** #1308]. The authors show that solving the problem of minimizing $\sum_{i=1}^m \sum_{j=1}^n c_{ij} x_{ij}$ subject to $\sum_{j=1}^n x_{ij} = a_i$ ($i = 1, \cdots, m$), $\sum_{i=1}^m x_{ij} = b_j$ ($j = 1, \cdots, n$), $\sum_{j=1}^r x_{ij} \leq e_i$ ($i = 1, \cdots, m$; $0 < r < n$), $x_{ij} \geq 0$, is equivalent to solving the following ordinary transportation problem: Minimize $\sum_{h=1}^{2m} \sum_{j=1}^n c_{hj}' x_{hj}'$ subject to $\sum_{j=1}^n x_{hj}' = a_h'$ ($h = 1, \cdots, 2m$), $\sum_{h=1}^{2m} x_{hj}' = b_j'$ ($j = 1, \cdots, n$), $x_{hj}' \geq 0$, where

$$\begin{aligned} a_h' &= e_h & (h &= 1, \cdots, m), \\ &= a_{h-m} - e_{h-m} & (h &= m+1, \cdots, 2m), \\ b_j' &= b_j & (j &= 1, \cdots, n), \end{aligned}$$

$$\begin{aligned} c_{hj}' &= c_{hj} & (h &= 1, \cdots, m; j = 1, \cdots, n), \\ &= c_{h-m,j} & (h &= m+1, \cdots, 2m; j = r+1, \cdots, n), \\ &= C & (h &= m+1, \cdots, 2m; j = 1, \cdots, r), \end{aligned}$$

and C is sufficiently large.

The generalization to the case where one has the additional restriction $\sum_{i=1}^s x_{ij} \leq f_j$ ($j = 1, \cdots, n$; $0 < s < m$) is stated, and examples are provided.

Application of pseudo-Boolean programming to the theory of graphs.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **3**, 163–176 (1964).

A pseudo-Boolean function is a function F with domain the n-tuples $(x_1, \cdots, x_n)$, each $x_i = 0$ or 1, the x_i obeying the rules of operation of a Boolean algebra, and with range the real numbers. "Pseudo-Boolean Programming" is a term coined by the authors for a recursive scheme for minimizing such functions. In short the scheme is this. Given $F(x_1, \cdots, x_n)$, write it as $F = F_1(x_1, \cdots, x_n) = x_1\{F_1(1, x_2, \cdots, x_n) - F_1(0, x_2, \cdots, x_n)\} + F_1(0, x_2, \cdots, x_n) = x_1 g_1(x_2, \cdots, x_n) + h_1(x_2, \cdots, x_n)$. Clearly, if F_1 is to be minimized, then $g_1 > 0$ implies $x_1 = 0$; or, letting $S_1 = \{(x_2^*, \cdots, x_n^*) | g_1(x_2^*, \cdots, x_n^*) \leq 0\}$, $x_1 = 1$ only if $x_1^* = \sum_{S_1} \tilde{x}_2 \cdots \tilde{x}_n = 1$, where $\tilde{x}_i = x_i$ if $x_i^* = 1$ and $\tilde{x}_i = 1 - x_i$ if $x_i^* = 0$. Then, substitute $x_1 = x_1^*$ into F_1 to obtain $F_2(x_2, \cdots, x_n)$, a function in one fewer variables. Repeat to obtain finally $F_n(x_n) = x_n g_n + h_n$, g_n and h_n constants. If $g_n > 0$, let $x_n = 0$; if $g_n < 0$, let $x_n = 1$; if $g_n = 0$, take $x_n = 0$ or 1; then, iteratively, find $x_{n-1}, \cdots, x_1$ (there may be many solutions).

In this paper the authors apply this scheme to compute the chromatic number, the number of internal stability, the number of external stability and the kernels of a finite graph (for definitions of these, see Berge [*Théorie des graphes et ses applications*, Dunod, Paris, 1958; MR **21** #1608; English transl., Methuen, London, 1962; MR **24** #A2381]) by formulating appropriate pseudo-Boolean functions whose minima yield the required answers.

M. L. Balinski (Princeton, N.J.)

Wong, Eugene 6938

A linear search problem.

SIAM Rev. **6** (1964), 168–174.

A one-dimensional search problem is considered. A list $(x_i, f(x_i))$, $i = 1, \cdots, n$, is stored, the $\{x_i\}$ forming an ordered set with $x_j > x_k$ if $j > k$. It is desired to find $f(x)$ for some x in the list, given that the search proceeds by comparing x with some sequence of chosen arguments $\{x_{i_k}\}$. The problem is to choose the sequence in order to minimize the number of comparisons needed to find x. The author solves the problem through the recursive, functional equation approach of dynamic programming.

Bereanu, Bernard 6940

Régions de décision et répartition de l'optimum dans la programmation linéaire.

C. R. Acad. Sci. Paris **258** (1964), 1383–1386.

Let $t = (t_1, \cdots, t_r) \in T = \{t | \delta_j \leq t_j \leq \delta_j', 1 \leq j \leq r\}$ be a stochastic r-vector and $c_0, c_1, \cdots, c_r$ constant n-vectors. Define $c = c_0 + \sum_{i=1}^r c_i t_i$, and consider the linear program (I): Find $\gamma(t) = \min_{x \in X} c'(t)x$; $X = \{x | Ax = b, x \geq 0\} \neq \varnothing$, with the usual meaning for A, b, and x. Then, if X is bounded and all bases are non-degenerate, there exists a set of convex polyhedral sets $S_l \subset T$ $(1 \leq l \leq q)$, called "regions of decision" of (I), associated with a set of basic solutions $\hat{x}_l$ corresponding to basis B_l and a set of $(r+1)$-vectors $\alpha_l = (\alpha_{0l}, \alpha_{1l}, \cdots, \alpha_{rl})$ $(l = 1, 2, \cdots, q)$, such that (i) $\bigcup_l S_l = T$, (ii) $t \in S_l$ implies $\gamma(t) = c(t)\hat{x}_l = \alpha_{0l} + \alpha_{1l}t_1 + \alpha_{2l}t_2 + \cdots + \alpha_{rl}t_r$, (iii) $i \neq j$ implies $P\{t | t \in S_i \cap S_j\} = 0$. The regions S_l are described by systems of linear inequalities and the distribution function, the mean of $\gamma(t)$ and the probability that a given basis be optimal are obtained in terms of the probability distribution of t, the vectors α_l and the regions S_l. Finally, similar developments are obtained via duality, i.e., the vector b is assumed to be a stochastic variable given in the form $b = b_0 + \sum_{i=1}^r b_i t_i$ and the rest of the program coefficients to be constant. The proofs of all these results are to be published in a forthcoming paper.

A. G. Azpeitia (Amherst, Mass.)

Descloux, Jean 6941

Note on convex programming.

J. Soc. Indust. Appl. Math. **11** (1963), 737–747.

The author considers the problem of finding a point $\bar{x} \in E_n$ which minimizes the convex function $F(x) \equiv \max_{A \in \Omega}\{[A, x] - b(A)\}$ subject to $G(x) \equiv \max_{A \in \Lambda}\{[A, x] - c(A)\} \leq 0$. Here b and c are continuous real-valued functions on E_n, $[A, x]$ denotes the scalar product and the sets Ω and Λ of E_n are supposed to satisfy the Haar condition: each set of n vectors of $\Omega \cup \Lambda$ are linearly independent. The author describes an iterative method which yields a converging sequence x_k with $\lim x_k = \bar{x}$, if Ω and Λ are (possibly infinite) compact sets. His algorithm is a generalization of a method proposed by Cheney and Goldstein [Numer. Math. **1** (1959), 253–268; MR **22** #316] in the case of finite sets Ω and Λ. It consists in choosing a sequence of "bases" $I_k = \{A_k^1, \cdots, A_k^{n+1}\} \subseteq \Omega \cup \Lambda$, $I_k \cap \Omega \neq \varnothing$ so that (1) $I_k \cap I_{k+1}$ contains n elements, (2) 0 lies in the convex hull of I_k, and (3) the values $\mu_k = F_{I_k}(x_k)$ at the optimal points x_k of the restricted problem of minimizing $F_{I_k}(x) \equiv \max_{A \in I_k \cap \Omega}\{[A, x] - b(A)\}$, subject to $G_{I_k}(x) \equiv \max_{A \in I_k \cap \Lambda}\{[A, x] - c(A)\} \leq 0$, increase strictly if $x_k \neq \bar{x}$.

J. Stoer (Munich)

Hanson, M. A. 6942

Stochastic non-linear programming.

J. Austral. Math. Soc. **4** (1964), 347–353.

Let Y be a subset of E_m and let $y \in Y$ have the scalar distribution $\psi(y)$, where ψ is C'' on Y. Let X be a subset of E_n and let $S = X \times Y$. Let $\phi(x, y)$ be a scalar-valued function on S with range in E_r and let $h(x, y)$ be a vector-valued function on S with range in E_s. The problem considered is the following one. Determine an x_0 in X that minimizes $\mathscr{E}\phi(x, y)$ subject to the constraints $\mathscr{E}g(x, y) \geq 0$ and $h(x, y) \geq 0$ for all y in Y, where

$$\mathscr{E}f(x, y) = \int_Y f(x, y)\psi(y)\, dy.$$

The analysis of the problem is carried out under certain assumptions on the constraints g and h.

The first theorem of the paper gives necessary conditions for a minimizing x_0, analogous to the multiplier rule and the Kuhn-Tucker conditions. The second theorem asserts that under appropriate concavity and convexity hypotheses on ϕ, g, and h, the necessary conditions are also sufficient. The third theorem is a duality theorem that asserts that under the convexity and concavity hypotheses of Theorem 2, the minimizing x_0 is also the maximizing x_0 for an appropriately defined maximizing problem.

{Reviewer's note: The statements of the three theorems are incorrect. Statement (4) of Theorem 1 should read $\mathscr{E}(\phi_x+\lambda g_x)+\mu(y)h_x(x,y)=0$, and appropriate changes should be made in the corresponding statements of Theorems 2 and 3. The various proofs can be readily modified to accommodate the correct statements. The reviewer finds the proof that $\lambda\leq 0$ and $\mu\leq 0$ somewhat obscure. In particular, the ability to choose x^* as described on page 350 is not clear, since the condition $\|x-x^*\|^2=o(|g^j(x,y)-g^j(x^*,y)|)$ implies that if $x\neq x^*$, then $g^j(x,y)\neq g^j(x^*,y)$ for all components g^j of g such that $g^j(x,y)=0$. Finally, there seems to be some confusion between $\mathscr{E}g^j(x,y)$ and $g^j(x,y)$ throughout the proof of Theorem 1 on page 350.}

L. D. Berkovitz (Lafayette, Ind.)

Messikommer, B. 6943

Die Optimierung eines halbkontinuierlichen chemischen Reaktors mittels dynamischer Programmierung.

Analogue Computation Applied to the Study of Chemical Processes (*Proc. Internat. Seminar, Brussels*, 1960), *pp.* 16–21. *Presses Acad. Européennes, Brussels*, 1961; *Gordon and Breach, New York*, 1962.

In chemical engineering it frequently happens that the output of one stage of processing is used as the input to the next. This suggests that it may be fruitful to view them as dynamic programming processes for the purpose of optimization. Beginnings have been made in recent books [cf., e.g., R. Aris, *The optimal design of chemical reactors*, Academic Press, New York, 1961; MR **23** #B473]. This interesting and well-written paper shows how to formulate the reaction rate and mass balance equations, apply Bellman's principle of optimality, and employ a Lagrange multiplier to simplify the calculations. It is suggested that an analogue computer (with some auxiliary logical circuitry) be used, and some numerical results are quoted. The paper is accessible to both mathematicians and chemical engineers.

Mangasarian, O. L.; Stone, H. 6944

Two-person nonzero-sum games and quadratic programming.

J. Math. Anal. Appl. **9** (1964), 348–355.

Authors' summary: "It is shown that a necessary and sufficient condition that a point be a Nash equilibrium point of a two-person nonzero-sum game with a finite number of pure strategies is that the point be a solution of a single programming problem with linear constraints and a quadratic objective function that has a global maximum of zero. Every equilibrium point is a solution of this programming problem. For the case of a zero-sum game, the quadratic programming problem degenerates to the well-known dual linear program associated with the game."

The quadratic objective function is not necessarily concave, but the authors suggest that, on the basis of computational experience, the gradient projection method works satisfactorily nevertheless; since the value of the global maximum is known, local maxima may easily be rejected.

Tsetlin, M. L. [Cetlin, M. L.]; Krylov, V. Yu. [Krylov, V. Ju.] 6945

Examples of games with automata.

Dokl. Akad. Nauk SSSR **149** (1963), 284–287 (*Russian*); *translated as Soviet Physics Dokl.* **8** (1963), 232–234.

This short paper gives a general definition and two examples of games in which the players are finite automata playing a game repeatedly. For each play of the game a strategy is chosen which determines the probability of a win or loss of one unit for each player; information on the wins or losses in any one play is used to determine the strategy for the following play.

In one of the examples, a game is defined between two automata in which one of the players wins and the other loses in every play. The players are assumed to be employing a type of strategy called a "linear tactic", which was defined in a previous paper [Cetlin, same Dokl. **149** (1963), 52–53; MR **26** #3531]. For such a game a limiting expectation W is shown to exist and to satisfy certain properties depending on the payoff matrix. If the payoff matrix has a row (or column) with all entries non-negative, then W is said to be equal to the harmonic mean of the elements of this row (or column), otherwise $W=0$.

On a certain concept of value of information in games.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp.* 29–33. *Publ. House Czech. Acad. Sci., Prague*, 1964.

The author restates the definitions of game value and optimal strategies in terms of a quantity that measures what happens to the sup-inf payoff of a player when the other player unilaterally restricts the set of mixed strategies at his disposal.

R. J. Aumann (New Haven, Conn.)

Fleming, Wendell H. 6947

The convergence problem for differential games. II.

Advances in game theory, pp. 195–210. *Princeton Univ. Press, Princeton, N.J.*, 1964.

In a differential game, the motion of a point ξ in euclidean space E^r during a time interval T is influenced by strategic choices made by two players at each instant of T. The payoff is $U[\xi(T)]+\int_0^T f(\xi(t), y(t), z(t))\,dt$, where y and z are the strategic variables under the control of the two players; the way in which y and z affect the motion of ξ may be described by a differential equation $\dot{\xi}=g(\xi,y,z)$. Rigorizing the above description is a non-trivial task. The approach used by the author is to divide T into N equal time units and to allow the players to make their choices at the beginning of each unit only; denote the value of such a "discretized" game by V_N. In a previous

paper [J. Math. Anal. Appl. **3** (1961), 102–116; MR **25** #5806] the author showed that V_n converges as $n\to\infty$, if certain rather restrictive assumptions are made about f and g. In this paper convergence is proved without any of those restrictive assumptions. The proof makes use of a number of recent results on non-linear parabolic differential equations.

Thrall, R. M.; Lucas, W. F. 6948

n-person games in partition function form.

Naval Res. Logist. Quart. **10** (1963), 281–298.

Let N be a set with n members, called players. A partition of N is a family of disjoint subsets of N whose union is N. A partition function F assigns to each partition P and each member P_i of P a real number $F_P(P_i)$; a pair (N, F) is called a game in partition function form. The partition function generalizes the von Neumann-Morgenstern (N-M) characteristic function [von Neumann and Morgenstern, *Theory of games and economic behavior*, Princeton Univ. Press, Princeton, N.J., 1944; MR **6**, 235]; unlike the characteristic function, the partition function allows the payoff to a coalition M to depend on how the players outside M have combined into coalitions.

The notions of imputation, domination, effectiveness, core and solution are defined in a manner analogous to the N-M definitions. The results, however, are quite different. For example, the standard simplex of imputations in the N-M theory is replaced by a finite number of parallel simplices, and a single solution may have pieces in several of these simplices.

All solutions are found for all 2- and 3-person games, and for games in which $F_{(N)}(N)$ is sufficiently large compared to the other values of F (in which case the other values do not matter). The most interesting games discussed are the general 3-person games; it turns out that in comparison with the N-M 3-person results, the individual solutions are often larger, but there are usually fewer solutions and often the solution is unique.

Bemerkungen zum Aumannschen Core-Theorem.

Z. Wahrscheinlichkeitstheorie und Verw. Gebiete **3**, 148–153 (1964).

A simplification of the theory of cooperative games without side payments due to Peleg and the reviewer [Bull. Amer. Math. Soc. **66** (1960), 173–179; MR **22** #10802] (the AP theory) is presented. In the author's approach, a game is characterized entirely by its characteristic function, and the compact polyhedron H of "actually feasible" payoff vectors in the AP theory is replaced by $v(N)$, where N is the set of all players. The author shows that many of the theorems of AP theory carry over to his version. In particular, in a given game let $\bar{E}$ be the set of feasible payoff vectors (H in the AP theory, $v(N)$ in the author's); E and $\bar{A}$ the sets of group rational and individually rational members of $\bar{E}$, respectively; and $A = E\cap\bar{A}$. The reviewer has shown [Trans. Amer. Math. Soc. **98** (1961), 539–552; MR **23** #B483] that the cores associated with all four of these sets coincide in the AP theory. The author shows that a much simpler proof of this theorem can be given in his theory.

A property of stability possessed by certain imputations.

Advances in game theory, pp. 513–529. *Princeton Univ. Press, Princeton, N.J.*, 1964.

Let v be a constant-sum superadditive characteristic function on a player set I. A coalition structure (c.s.) is a family F of subsets of I with the properties: $I\in F$, $\varnothing\notin F$; every S in F with more than one player splits uniquely into a pair of elements of F (called the parties of S, and co-parties of each other); every S in F other than I is a party of precisely one member of F. Intuitively, the members of F are bargaining units; once it is determined that an S in F receives the total payoff $w(S)$, the parties of S bargain for their share of $w(S)$, and this process continues until the payoff of each player is determined. The author proves that with each c.s. F it is possible to associate an imputation w so that: (1) If I_1 and I_2 are the parties of I, then $w(I_1)=v(I_1)$ and $w(I_2)=v(I_2)$, where $w(S)=\sum_{i\in S} w_i$; (2) Let S_1 and S_2 be parties of an S in F, S_3 the co-party of S, F_1 $[F_2]$ the c.s. obtained from F by deleting S and adding $S_1\cup S_3$ $[S_2\cup S_3]$, and w_1 $[w_2]$ the imputation associated with F_1 $[F_2]$; then $w(S_1)=\frac{1}{2}\{w(S)+w_1(S_1\cup S_3)-w_2(S_2\cup S_3)\}$, and similarly for S_2. Intuitively, (2) says that S_1 and S_2 share $w(S)$ in such a way that any threat by S_1 $[S_2]$ to get a larger payoff by teaming up with S_3 can be matched with similar arguments by S_2 $[S_1]$. The w satisfying (1) and (2) is unique, and the author derives a formula for it in terms of v.

Pears, A. R. 6952

On topological games.

Proc. Cambridge Philos. Soc. **61** (1965), 165–171.

The games considered are those introduced by Berge [*Contributions to the theory of games*, Vol. 3, pp. 165–178, Princeton Univ. Press, Princeton, N.J., 1957; MR **19**, 1147], converted into two-person constant-sum games by confining the investigation to maximin questions. The author finds two systems of sufficient conditions for the existence of maximin strategies.

J. R. Isbell (New Orleans, La.)

Kuznecov, I. N. 6953

Optimal distribution of bounded means for convex-concave payoff functions. (Russian)

Izv. Akad. Nauk SSSR Tehn. Kibernet. **1964**, no. 5, 100–106.

Author's summary: "Conditions are found, the fulfillment of which guarantees an optimal distribution $\varphi(x)$ of bounded mean Φ over the space X. The distribution is called optimal if it gives the largest value to the mean payoff. The investigation is carried out for a known a priori probability $p(x)\,dx$ obtained from the payoff $P(\varphi, x)\,dx$, where the payoff function $P(\varphi, x)$ has an interval $(0, \varphi_1)$ of convexity downward and the interval (φ_1, ∞) of convexity upward."

W. Fleming (Providence, R.I.)

Hershkowitz, Martin 6954

A computational note on von Neumann's algorithm for determining optimal strategy.

Naval Res. Logist. Quart. **11** (1964), 75–78.

The author compares the speeds of convergence of the following forms of iterative methods for solving matrix games by applying them to some numerical examples: (1) von Neumann's Predictor-Corrector Algorithm, (2) The Simplex Method, (3) Brown's Fictitious Play, and (4) A Relaxation Method. He draws the conclusion that the von Neumann algorithm is inferior to the others.

BIOLOGY AND BEHAVIORAL SCIENCES

Ewens, W. J. 6955

The diffusion equation and a pseudo-distribution in genetics.

J. Roy. Statist. Soc. Ser. B **25** (1963), 405–412.

Consider the distribution function $F(x;t)$ $(0 \leq x \leq 1)$ of a variate x at time t whose density function $f(x,t)$ satisfies the forward Kolmogorov equation

$$\frac{\partial f(x;t)}{\partial t} = \frac{1}{2}\frac{\partial^2}{\partial x^2}\{v(x)f(x;t)\} - \frac{\partial}{\partial x}\{m(x)f(x,t)\}.$$

Here $m(x)$ and $v(x)$ are the instantaneous drift and diffusion coefficients, respectively. The particular case $m(x) = x(1-x)\phi(x)$, $v(x) = ax(1-x)$, where $\phi(x)$ is an arbitrary polynomial (possibly constant or zero) and a is a constant, is found in genetical applications. This implies that $x=0$, $x=1$ are "exit" boundaries. This corresponds in genetics to the fixation of a certain gene in a population.

If we solve the "stationary" equation

$$\frac{1}{2}\frac{d^2}{dx^2}\{v(x)f(x)\} - \frac{d}{dx}\{m(x)f(x)\} = 0,$$

we obtain successively

$$\frac{1}{2}\frac{d}{dx}\{v(x)f(x)\} - m(x)f(x) = c_1,$$

and

$$f(x) = \frac{c_2\psi(x)}{v(x)} + \frac{2c_1}{v(x)}\psi(x)\int^x \{\psi(y)\}^{-1}\,dy,$$

which we may alternatively write (if $c_1 \neq 0$)

$$f(x) = \frac{2c_1}{v(x)}\psi(x)\int_c^x \{\psi(y)\}^{-1}\,dy,$$

where the constant c is related to c_2.

An interpretation of $f(x)$ as a description, in a certain sense, of the transient behaviour of the diffusion process is given. Interpretations of other solutions, obtained by a different allocation of constants, are given. An analogous function for a certain discrete process is exhibited.

Kybernetische Modelle in der Demographie.

Mathematische und physikalisch-technische Probleme der Kybernetik, pp. 97–103. *Akademie-Verlag, Berlin*, 1963.

Cybernetic (self-regulating) models are employed for the elucidation of several well-known relations in biometrics, e.g., sex-ratio at birth, influence in changes in pre- and post-natal mortality and the like.

C. J. Maloney (Bethesda, Md.)

Kruskal, J. B. 6957

Multidimensional scaling by optimizing goodness of fit to a nonmetric hypothesis.

Psychometrika **29** (1964), 1–27.

Let E be a metric space with metric d. Let there be given a rank order $\succ$ on the $\frac{1}{2}n(n-1)$ pairs (i,j) of integers from 1 to n with $i<j$. A configuration is an n-tuple $X = (x_1, \cdots, x_n)$ of points in E, not all equal; it is a perfect scale for the given order if $(i,j) \succ (k,m)$ is equivalent to $d(x_i, x_j) > d(x_k, x_m)$. There may not be a perfect scale. For each X, the author defines the stress $S(X)$ as the infimum of $[\sum_{i<j}(d(x_i,x_j) - \hat{d}_{ij})^2/\sum_{i<j} d^2(x_i,x_j)]^{1/2}$, taken over all choices of $\frac{1}{2}n(n-1)$ numbers $\hat{d}_{ij}$ such that $\hat{d}_{ij} > \hat{d}_{km}$ is equivalent to $(i,j) \succ (k,m)$; $S(X)$ measures the failure of X to be a perfect scale. The stress of the order is defined as the minimum of $S(X)$ over all X; it measures the failure of the order to have a perfect scale in E. E is usually taken to be a euclidean space of fixed dimension with one of the l^p metrics, $1 \leq p \leq \infty$. This definition provides a basis for techniques in psychology where dissimilarities between n objects are matched by distances between n points. A novelty of the author's approach is that only the rank order of the dissimilarities is used, not any cardial measure of their size. Examples are given.

★Language and information. Selected essays on their theory and application.

Addison-Wesley Series in Logic.

Addison-Wesley Publishing Co., Inc., Reading, Mass.-London; The Jerusalem Academic Press, Ltd., Jerusalem, 1964. x + 388 pp. $12.50.

This volume contains a reprinting of twenty of the author's papers, and is arranged as follows. Part I: four papers on the theoretical aspects of language; Part II: five papers on algebraic linguistics; Part III: five papers on machine translation; Part IV: three papers on semantic information; Part V: three papers on the mechanization of information retrieval.

In a 16-page introduction the author reminisces a bit about the writing of various of the papers. More important, the author recounts his experiences with machine translation and the widely discussed problem of information retrieval (which has become stigmatized by the clichés "publication explosion" and "information and documentation explosion"), and the last paper in Part V (entitled "Is Information Retrieval Approaching a Crisis?" and reprinted from American Documentation 14 (1963), 95–98) provides a sensible contrast to many of the amateur *coups d'œil* (e.g., Derek J. de Solla Price, *Little science, big science* [Columbia Univ. Press, New York, 1963]), which now seem to constitute a second-level publication explosion. *A. J. Lohwater* (Providence, R.I.)

Oettinger, A. G. 6960

An essay in information retrieval or the birth of a myth.
Information and Control 8 (1965), 64–79.

Author's summary: "A frequently quoted and still current myth on the ill effects of the so-called information explosion is analyzed. Five years and 250,000 dollars were allegedly spent in the United States to duplicate the result published in the Soviet Union in 1950. Not only does this myth rest on a comedy of errors, but the trivial results in question were surprisingly well known to all specialists most concerned, in at least one instance as early as 1937."

The comedy of errors refers to the use made of a paper of A. G. Lunc [Dokl. Akad. Nauk SSSR 70 (1950), 421–423; MR 11, 574] by over-zealous proponents in the area of information retrieval [for some interesting comments on such zealotry see some of the reminiscences in #6959 reviewed above]. As Oettinger points out, the myth was even carried to the floor of the U.S. Congress by the Hon. Roman C. Pucinski, who asserted that a "team of top-notch mathematicians" worked for five years to obtain an independent solution of a relatively trivial and unimportant result. The paper continues with a selection from the luxuriant growth of the second-level publication concerning scientific publication, so thickly has this rainforest proliferated that highly relevant references have been overlooked [e.g., R. P. Boas, Jr., Science 125 (1957), 1260], fortunately, however, without the loss of enough money to cause comment on the floor of the U.S. Congress. The question may be asked: Would it have been cheaper to train this "team of top-notch mathematicians" in the simplest research techniques, the use of journals and reference tools, etc., than to deluge them with a third-level publication of print-out matter containing (hopefully) all possible applications and corollaries of a given result. Boas's earlier strictures [loc. cit.] still indicate that no easy substitute for competent scholarship is yet in sight.

The second part of the paper contains an illustration of how the Lunc paper in question might be translated.

Aczél, J.; Daróczy, Z. 6961

Über verallgemeinerte quasilineare Mittelwerte, die mit Gewichtsfunktionen gebildet sind.
Publ. Math. Debrecen 10 (1963), 171–190.

Let I be an interval on the real line, let φ be a strictly monotone continuous function on I and let f be a non-negative continuous function on I not vanishing on any subinterval of positive length. The generalized quasi-linear mean value of points $x_1, x_2, \cdots, x_n \in I$ is defined by the formula

$$M_\varphi(x_i, f) = \varphi^{-1}\left[\sum_{i=1}^{n} f(x_i)\varphi(x_i) \Big/ \sum_{i=1}^{n} f(x_i)\right].$$

In the first portion of this paper the authors obtain a necessary and sufficient condition that the equality of mean values $M_\varphi(x_i, f) = M_\psi(x_i, g)$ holds. Next they investigate the equation of homogeneity $M_\varphi(tx_i, f) = tM_\varphi(x_i, f)$. They prove that the problem of determining all homogeneous generalized quasi-linear mean values is equivalent to the problem of determining all solutions of a vector-matrix functional equation. After solving this functional equation they are able to give explicit expressions for all those generalized quasi-linear mean values which satisfy the homogeneity equation. In the last paragraph of the paper the authors remark that since, in some cases, $M_\varphi(x_i y_i, f) = M_\varphi(x_i, f) M_\varphi(y_i, f)$, there would appear to be some applications of their mean value theory to the entropy concept of information theory. They show that the two (classical) definitions of entropy

$$I_\alpha(x_i) = \frac{1}{1-\alpha} \log\left(\sum_{i=1}^{n} x_i^\alpha \Big/ \sum_{i=1}^{n} x_i\right) \qquad (\alpha \neq 1),$$

$$I_1(x_i) = -\sum_{i=1}^{n} x_i \log x_i \Big/ \sum_{i=1}^{n} x_i$$

[A. Rényi, *Wahrscheinlichkeitsrechnung. Mit einem Anhang über Informationstheorie*, VEB Deutscher Verlag, Berlin, 1962; MR 26 #5597] are special cases of their results. Finally some open problems are discussed.
G. Maltese (College Park, Md.)

Umegaki, Hisaharu 6962

General treatment of alphabet-message space and integral representation of entropy.
Kôdai Math. Sem. Rep. 16 (1964), 18–26.

Instead of the "message space" A^I consisting of all doubly infinite sequences $a = (\cdots, a_{-1}, a_0, a_1, \cdots)$ (where the a_i's belong to some finite set A) the author considers more generally a totally disconnected compact Hausdorff space X with a fixed homeomorphism S onto itself, playing the role of the shift. Theorems on entropy (more exactly: entropy rate) of information sources are generalized for this abstract set-up, the proofs being similar to the original ones. In particular, for any "clopen" partition $\mathfrak{L}$ (i.e., partition consisting of closed-open sets) the existence of a universal bounded, non-negative, S-invariant Borel-measurable function $h(x) = h(x, \mathfrak{L}, S)$ is proved such that for every S-invariant regular probability measure p on X, $H(p) = \int_X h(x)\,dp(x)$ and

$$h(x) = h_p(x) = -\sum_{U \in \mathfrak{L}} P_p(U | \mathfrak{L}_\infty)(x) \log P_p(U | \mathfrak{L}_\infty)(x)$$

for p—a.e. $x \in X$. Here the entropy $H(p) = H(p, \mathfrak{L}, S)$ is defined—as usual in ergodic theory—as the limit $\lim_{n\to\infty} (1/n) H(\bigvee_{k=0}^{n-1} S^{-k}\mathfrak{L})$, and $P_p(U | \mathfrak{L}_\infty)(x)$ denotes the

conditional probability with respect to the σ-field generated by $\{S^{-k}\mathfrak{Q}\}_{k=1}^{\infty}$ with underlying probability measure p. For the case $X = A^I$ this theorem was proved by K. R. Parathasarathy [Illinois J. Math. **5** (1961), 299–305] and independently by K. Jacobs [Math. Z. **78** (1962) 33–43; MR **26** #286]. The functional $H(\xi) = \int_X h(x)d\xi(x)$ defined on the Banach space of all S-invariant bounded regular signed measures ξ on X coincides with the entropy functional introduced by the author [Kôdai Math. Sem. Rep. **15** (1963), 162–175; MR **28** #2189].

I. Csiszár (Budapest)

Umegaki, Hisaharu 6963a

A functional method for stationary channels.

Kôdai Math. Sem. Rep. **16** (1964), 27–39.

Umegaki, Hisaharu 6963b

Supplement and correction to the preceding paper "A functional method for stationary channels".

Kôdai Math. Sem. Rep. **16** (1964), 189–190.

An abstract generalization of the concept of a stationary channel is given, by replacing the input and output message spaces A^I and B^I by arbitrary compact Hausdorff spaces X and Y with fixed homomorphisms S and T, respectively, playing the role of the shift. Assuming further that X and Y are totally disconnected spaces, the results of the author's paper above [#6962] can be applied, and theorems on the integral representation of the transmission functional are proved. Here the transmission functional $\Re(\xi; \mathfrak{Q}, \mathfrak{G})$ corresponding to given "clopen" partitions $\mathfrak{Q}$ of X and $\mathfrak{G}$ of Y is defined with the aid of the entropy functional [cf. #6962 above] analogously to the usual definition of transmission rate. The exact analogue of K. R. Parathasarathy's theorem [Illinois J. Math. **5** (1961), 299–305] is proved under an additional measurability hypothesis called (Cl'); hence, by introducing

$$C_s = \sup\{\Re(p; \mathfrak{Q}, \mathfrak{G}), p \in \mathbf{P}(X, S)\},$$

the equality

$$C_s = \sup\{\Re(p; \mathfrak{Q}, \mathfrak{G}), p \in \mathbf{P}_e(X)\}$$

follows, where $\mathbf{P}(X, S)$ and $\mathbf{P}_e(X)$ denote the set of all S-invariant probability measures and all ergodic probability measures on X, respectively. Also, the abstract version of R. L. Adler's theorem [Proc. Amer. Math. Soc. **12** (1961), 924–930; MR **24** #B2504] on equality of stationary (C_s) and ergodic (C_e) capacities is stated. In the original paper the capacity C_s is stated to be attained (for some $p \in \mathbf{P}_e(X)$) under a continuity hypothesis; in the supplement, however, the proof of this statement is pointed out to be incorrect. Further, in the supplement, the author points out that the integral representation theorem of Parathasarathy type and its consequence

$$C_s = \sup\{\Re(p; \mathfrak{Q}, \mathfrak{G}), p \in \mathbf{P}_e(X)\}$$

are valid for arbitrary compact metric spaces X and Y and arbitrary finite measurable partitions $\mathfrak{Q}$ and $\mathfrak{G}$.

Širjaev, A. N. 6964

Detection of randomly appearing targets in a multichannel system. (Russian)

Trudy Mat. Inst. Steklov. **71** (1964), 113–117.

Results of the author [Teor. Verojatnost. i Primenen. **8** (1963), 431–443; MR **28** #649] are extended to observation of the outputs, not of one, but of n independent channels with equal signal-to-noise ratios (SNR). A target is declared present in a given direction if the output of at least one channel exceeds a threshold after that direction is observed for a fixed time T_0. The mean time $\tau(T, N, n)$ between appearance of a target and its detection is for $T \to \infty$ asymptotically $\tau(T, N, n) \sim \frac{1}{2}(N+2) \ln T$, where N is the number of directions observed and T is the mean time between false alarms, provided $\ln n = o(T_0)$. The unit of time is $\Delta/(\mathrm{SNR})$, where Δ is the sampling interval.

C. W. Helstrom (Pittsburgh, Pa.)

Cooper, David B.; Cooper, Paul W. 6965

Nonsupervised adaptive signal detection and pattern recognition.

Information and Control **7** (1964), 416–444.

Authors' summary: "Adaptive signal detection and pattern recognition can be viewed as a problem in statistical classification wherein the partitioning of an n-dimensional sample space into category (signal) regions is determined through estimation from a set of samples from the categories. When the correct associations of the samples are known, the problem is the commonly treated supervised one. This paper, examining the nonsupervised case wherein the correct associations of the samples are unknown, demonstrates that it is possible under extremely general conditions to achieve effective adaptation without supervision. With particular emphasis on a two-category (binary detection) model, general conditions are described under which nonsupervised adaptation is possible, and specific simple yet rapidly convergent techniques are presented under varying degrees of prior knowledge of the statistical properties of the data.

"Most of the paper is concerned with a two-category case where the corresponding (equiprobable) distributions differ only in location. The paper proceeds by examining the over-all probability distribution comprised of the two-component category distributions, and the adaptation treated is directed toward determining the decision boundary, or the distribution parameters necessary for defining it. For univariate normal distributions, various estimators (and their convergence properties) of the over-all mean are examined. For multivariate monotone (including normal) distributions the over-all sample covariance matrix is used to obtain the component covariance matrices when these are general (including the colored noise case), or simply to obtain the principal eigenvector (of the overall matrix) when the component distributions are spherically symmetric (white noise). A hill-climbing algorithm is included. These results for the important model of binary signal detection in gaussian noise demonstrate that no prior knowledge of the signal or noise parameters is required for nonsupervised adaptation to the optimum detector. It is shown in one dimension that for equiprobable component distributions of almost any functional form and differing only by translation we can obtain category distribution estimators which converge uniformly over the real line with probability 1. Considered also are the case of different a priori probabilities, the problem of tracking, and some aspects of the multiple-category problem."

★**Lingvistică matematică. Modele matematice în lingvistică [Mathematical linguistics. Mathematical models in linguistics].**

Editura Didactică şi Pedagogică, Bucharest, 1963. 220 *pp*. *Lei* 9.40.

This book is based in part on a course in mathematical linguistics given by the author at the University of Bucharest in the years 1961 through 1963. The orientation of the book is based on the notion of opposition due to F. de Saussure, which led N. Trubetzkoy to construct a classification of different types of phonological opposition, and which was later improved by J. Cantineau. The further investigations of A. Martinet, L. Hjelmslev, Z. Harris, N. Chomsky, A. Reformatski, I. Revzin, R. Dobrušin, and S. Šaumyan form the basis for the author's treatment.

The style is distinctly mathematical (i.e., definition, theorem, proof) and is sprinkled with appropriate introductions, observations, and examples (Roumanian and Russian). The only mathematical preparation needed is a knowledge of elementary set theory, relation theory, combinatorial algebra, logic, and mappings.

The scope of the book is indicated by the following chapter headings: Logical theory of linguistic opposition, The phoneme, morphemes and quasimorphemes, Functional methods in morphemic analysis, Grammatical categories, Models based on partitions and on the relation of government, and Mathematical modeling of the parts of speech. The bibliography contains an extensive list of 301 references covering the work of American and European linguists. Unfortunately, the book will have little influence on English-speaking linguists since it is in Roumanian.

H. P. Edmundson (Pacific Palisades, Calif.)

Gladkiĭ, A. V. 6967

Grammars with linear memory. (Russian)

Algebra i Logika Sem. **2** (1963), no. 5, 43–55.

Let G denote a grammar, let $L(G)$ denote the language generated by G, and let $|W|$ denote the length of the word $W \in L(G)$. Call G a linear bounded grammar ("grammar with linear memory" in the author's terminology) if there exists a natural number k such that for any word $W \in L(G)$, obtained, say, by a derivation $S = W_0 \to W_1 \to \cdots \to W_n = W$ one has that $|W_i| \leq k|W|$, $i = 0, 1, \cdots, n$. (Through a misprint, the "k" is omitted in the definition, but later usage in the paper suggests that this is what the author intended.) It is shown that the class of linear bounded languages coincides with the class of context-sensitive languages, that any language accepted by a bounded linear automaton ("any language recognizable by linear memory" in the author's terminology) is a bounded linear language, hence, context-sensitive, and, finally, that the intersection of any finite set of linear bounded languages is again a linear bounded language. (Thus the results overlap those of Landweber [Information and Control **6** (1963), 131–136; MR **29** #3291]; see also the following review [#6968].)

R. M. Baer (Berkeley, Calif.)

Kuroda, S.-Y. 6968

Classes of languages and linear-bounded automata.

Information and Control **7** (1964), 207–223.

Here a linear bounded grammar is defined as a context-sensitive grammar which is of order 2, is length-preserving, and satisfies: $S \to EF$ implies $E = S$, the initial symbol. (The order of a grammar is the maximum of the lengths of strings occurring in the rules.) For any context-sensitive grammar there is an equivalent linear bounded grammar. The converse of a result of Landweber [see #6967 above for reference], when shifted to the context of nondeterministic linear bounded automata, yields a characterization of the context-sensitive languages as those accepted by (nondeterministic) linear bounded automata. And, among other results, it is shown that the context-free languages are accepted by (deterministic) linear bounded automata.

At one point the author introduces a linear bounded automaton coupled to a certain type of counter (which presumably is just a second tape) and claims that the resulting device is again a linear bounded automaton. This point deserves a bit more discussion than is accorded it in the text.

R. M. Baer (Berkeley, Calif.)

Zítek, František 6969

Quelques remarques au sujet de l'entropie du tchèque.

Trans. Third Prague Conf. Information Theory, Statist. Decision Functions, Random Processes (*Liblice*, 1962), *pp*. 841–846. *Publ. House Czech. Acad. Sci., Prague*, 1964.

The author makes two remarks about certain information-theoretic properties of the Czech language. The first remark concerns the entropy of written Czech using a modification of the method used by M. H. Hansson on Swedish, in which native speakers guess a phrase letter-by-letter. As an estimate of the entropy, a sample mean of $H = 2.40$ is obtained. The second remark concerns the morphological homonymity present in Czech grammar in comparison with that of Latin, German (with the definite article), and German (without the definite article). The analysis uses simple concepts from the theory of partitions, and the entropies for nouns are summarized in a table.

H. P. Edmundson (Pacific Palisades, Calif.)

Rozenvasser, E. N. 6970

Theory of a linear system with stationary time lag and periodically varying parameter. (Russian. English summary)

Avtomat. i Telemeh. **25** (1964), 1067–1074.

Continuing his earlier work [Avtomat. i Telemeh. **21** (1960), 15–19; MR **22** #9385; ibid. **21** (1960), 1279–1292; MR **22** #9422; Prikl. Mat. Meh. **25** (1961), 284–293; MR **24** #A1474; *Analytic methods in the theory of non-linear vibrations*, Proc. Internat. Sympos. Non-linear Vibrations, Vol. I, 1961, pp. 417–424, Izdat. Akad. Nauk Ukrain. SSR, Kiev, 1963; MR **27** #5998], the author studies a linear system written in operational form as follows: (1) $y = W(p)x$, $x = \mu\varphi(t)y$, where (2) $W(p) = \exp(-p\tau)\cdot M(p)/D(p)$, where M and D are polynomials in p, μ is a scalar, and φ is continuous in t, of period T. (1) is derived apparently by Laplace transform techniques. By using results of the paper cited above, the author derives a characteristic equation, whose roots serve to determine the stability of (1). Then a Floquet representation of a certain solution of (1) is obtained, where the roots of the characteristic equation appear as characteristic exponents.

A. Stokes (Washington, D.C.)

Egorov, A. I. 6971

A variational problem in the theory of equations of elliptic type. (Russian)

Sibirsk. Mat. Ž. **5** (1964), 500–508.

Let D be an open bounded subset of 3-dimensional space, with smooth boundary S, and let U be some bounded subset of r-dimensional space. The problem is to choose $u(x)$ with values in U to minimize

$$I = \iint_S \alpha(x)z(x)\,dS + \iiint_D \beta(x)z(x)\,dx,$$

where the function z is determined in D by the partial differential equation $\Delta z = F(x, z, u(x))$, where Δ is the Laplace operator, together with the data $dz/dn + hz = f(x)$ on S, $h > 0$. The function F is assumed to satisfy a Lipschitz condition in (z, u). The main result is the maximum principle in the following form. Let $w(x)$ satisfy the linear partial differential equation

$$\Delta w = \frac{\partial F(x, z(x), u(x))}{\partial z} w - \beta(x)$$

with the data $dw/dn + hw = \alpha(x)$ on S. Let

$$H = w(x)F(x, z(x), u).$$

If $u(x)$ is a piecewise smooth minimizing control, then H is maximum when $u = u(x)$.

A comparison between some methods for computing optimum paths in the problem of Bolza.

Computing Methods in Optimization Problems (Proc. Conf., Univ. California, Los Angeles, Calif., 1964), *pp.* 147–157. *Academic Press, New York,* 1964.

The author discusses modifications of the method of steepest ascent [Bryson and Denham, J. Appl. Mech. **29** (1962), 247–257; MR **26** #4822] and of the differential methods of Bliss [*Mathematics for exterior ballistics*, Chapter IV, Wiley, New York, 1944; MR **6**, 24] for computing optimal trajectories. Advantages and disadvantages of each are listed, and suggestions are made concerning ways of combining the methods.

L. M. Graves (Chicago, Ill.)

Ewing, G. M.; Haseltine, W. R. 6973

Optimal programs for an ascending missile.

J. Soc. Indust. Appl. Math. Ser. A Control **2** (1964), 66–88.

An admissible program is defined to be an ordered triple of real-valued functions (v, y, m) defined on an interval $[0, T]$ and satisfying the following: (i) $v(0) = y(0) = 0$; (ii) $v(T) = V$, $y(T) = Y$, $m(T) = M$, where $M > 0$, $Y > 0$, $V \geq 0$ are fixed; (iii) v is in $L[0, T]$, m is non-increasing, and $y(t) = \int_0^t v(s)\,ds$; (iv) if $E(t) = \exp(c^{-1}(v(t) + gt))$, where g and c are positive constants, then, for every t_1, t_2 in $[0, T]$,

$$m(t_1)E(t_1) = m(t_2)E(t_2) + c^{-1}\int_{t_1}^{t_2} D[v(s), y(s)]E(s)\,ds.$$

The following problem is then posed. Does there exist an admissible program (v_0, y_0, m_0) such that if (v, y, m) is any other admissible program, then $m_0(0) \leq m(0)$. If so, what is the program (v_0, y_0, m_0), and is it unique.

It is shown, under reasonable assumptions about the drag function D, that a unique optimal program exists and has the following characteristics. If there is no drag or if Y is small and the drag is negligible, then the optimal program consists of an initial velocity boost followed by a coast. If for given Y, V is small, then the optimal program consists of an initial boost followed by a propulsive phase and then a coast. For Y and V both large the optimal program consists of an initial boost, a propulsive phase, and a terminal boost.

The proof of existence is accomplished by first showing that only programs whose velocities v are always nonnegative need be considered and that the velocity functions v_n in a minimizing sequence are of uniformly bounded variation. The existence then follows from Helly's theorem.

To characterize the solution and show uniqueness, the authors determine the trajectory Γ in (t, y)-space of a coasting program, and show that all other trajectories lie on one side of Γ. The analogue of a field in the calculus of variations is then constructed. By comparing admissible trajectories with trajectories of the field, it is shown that an optimal program must correspond to a unique trajectory of the field.

Vidal, Pierre 6974

Sur la réponse transitoire d'un système non linéaire échantillonné régi par une équation aux différences finies d'ordre *m*.

C. R. Acad. Sci. Paris **256** (1963), 5058–5061.

This brief note concerns a "sampled system" governed by the mth-order difference equation $x_{n+m} + f_1 x_{n+m-1} + \cdots + f_m x_n = 0$, where the f_i are functions of $x_n, \cdots, x_{n+m}$ and n. The equilibrium point of the system is taken to be the origin. For given initial conditions of the form $|x_1| = |x_2| = \cdots = |x_m| = c$, the "$b$ percent response time" is defined to be the shortest time, aT, such that $|x_{m+a}| \leq (b/100)c$. Here T is the "sampling period", i.e., the time step in the difference equation. It is shown that if the coefficients satisfy the condition $1 - \sum_{i=1}^m k^i|f_i| > d > 0$ with $k \geq 1$, then $|x_{m+j}| \leq k^{-j}|x_m|$, so that the b percent time is given by $bk^a > 100$. Somewhat surprising is the absence of references to the abundant literature on the subject.

The application of the methods of mathematical programming to an optimal control problem. (Russian)

Izv. Akad. Nauk SSSR Tehn. Kibernet. **1964**, *no.* 5, 16–29.

The paper considers the problem of time-optimality in control systems. Mathematical programming methods are used to find the control. The number of variables, the form of the constraints, and the method of solving the obtained problem essentially depend on the way in which the corresponding Cauchy problem is approximated. The cases of piecewise-constant and piecewise-linear approximations are considered in detail. Much attention is paid to the development of algorithms for solving the mathematical programming problems that arise. The usual time-optimal problem for the matrix system $\dot{X} = A(t)X + b(t)u(t)$, $X(0) = X_0$, $|u(t)| \leq 1$, is called Problem $\tilde{\mathrm{R}}_1$. If, in addition, the state variables are bounded, $|x_i(t)| \leq m_i$, $i = 1, \cdots, n$, we have Problem $\tilde{\mathrm{R}}_2$. The approach is to minimize the norm of X at fixed instants T (Problems $\tilde{\mathrm{R}}_1(T)$, $\tilde{\mathrm{R}}_2(T)$) and then to seek the minimal T for which the norm of X equals zero. The computational difficulties in these problems stem not only from the order of the state equations but also from the form of the integrand function in the Cauchy formula for the formal solution of the state equations. To obviate these difficulties, the integral in the Cauchy formula is approximated by a sum, and the problem reduces to seeking the minimum of a multivariable convex function in a closed region. The corresponding approximate problems are referred to as Problems $\mathrm{R}_1(T)$, $\mathrm{R}_2(T)$. A modification of the simplex method is used to solve these problems. The Kuhn-Tucker optimality criterion is also utilized for solving Problem $\mathrm{R}_1(T)$. These methods can be extended also to cases of piecewise-parabolic and piecewise-polynomial approximations. A third-order example is considered and solved for both the piecewise-constant and the piecewise-linear approximations. *N. H. Choksy* (Silver Spring, Md.)

Stratonovich, R. L. [Stratonovič, R. L.] 6981

On the theory of optimal control. Sufficient coordinates.

Avtomat. i Telemeh. **23** (1962), 910–917 (*Russian. English summary*); *translated as Automat. Remote Control* **23** (1963), 847–854.

A basic problem in automatic control is the selection of an "optimal" control decision on the basis of what is currently known. Frequently this means making decisions on the basis of the current values of the physical state variables in an effort to minimize the expected value of the future cost. Recently, though, Bellman and Kalaba, Zadeh, and others have emphasized the importance of adaptive control processes, in which the controller's knowledge of the dynamics, objectives, etc., of the process changes in the course of time. This brings with it the attendant problems of describing the controller's state of knowledge and how this changes in the light of experience gained during the process.

An axiomatic treatment is adumbrated, and several interesting examples are provided.

R. Kalaba (Santa Monica, Calif.)

Fattorini, H. O. 6982

Time-optimal control of solutions of operational differential equations.

J. Soc. Indust. Appl. Math. Ser. A Control **2** (1964), 54–59.

Let H be a Hilbert space with norm $|u|$, A a linear operator in H, and $f(t)$ a function on $t \geq 0$ into H. The problem considered is this: Given u, v in H, find an admissible control f such that the weak solution of the operational differential equation

$$(1)\qquad \begin{aligned} u'(t) &= Au(t) + f(t), \qquad t \geq 0, \\ u(0) &= u, \end{aligned}$$

reaches v in the smallest possible time. The definitions are

as follows. Let L_t be the space of functions on $(0, t)$ into H, strongly measurable and bounded, with

$$\text{norm } \|f\|_t = \text{ess sup}(|f(r)|,\ 0 \le r \le t).$$

Let $T(t)$ be the semigroup of bounded operators defined by $T(t)u(0) = u(t)$, where $u(t)$ is the strong solution of the homogeneous equation $u'(t) = Au(t)$. The weak solution of (1) is then defined for f in L_t by

$$u(t) = T(t)u + \int_0^t T(t-r)f(r)\,dr,$$

integration being in the sense of Bochner. Given u, v in H, an f in L_t is admissible if the weak solution of (1) reaches v at some t_0 and $\|f\|_t \le 1$, $0 \le t \le t_0$; it is optimal if t_0 is minimal.

It is proved that if for u and v in H there exists an admissible control, then there exists an optimal control, and that the optimal control uses the maximum available energy ($|f(r)| = 1$ a.e.) and is unique up to sets of measure zero. It is stated that the methods are applicable in wider situations, for example, when H is a reflexive Banach space or $A = A(t)$. No applications are indicated.

Permutation groups, complexes, and rearrangeable connecting networks.

Bell System Tech. J. **43** (1964), 1619–1640.

This paper presents an algebraic and combinatorial approach to the study of rearrangeability in connecting networks. Networks of this type are used in telephone systems, and they consist of arrangements of switches and transmission links through which inlets can be connected to outlets in many combinations. A network is rearrangeable if every assignment of inlets to outlets is realizable. The specific network form considered here is a sequence of switching stages connected by link patterns. A stage realizes a subgroup of the symmetric group of permutations, and a link pattern realizes a permutation. To obtain rearrangeability, the product of subgroups and permutations defined by the network should yield the symmetric group. Sufficient conditions (in terms of properties of stages and links) under which this is possible are formulated. The author indicates that these conditions do not provide new design principles, but they are intended to give new insights to the problem. A specific class of networks, that are generalizations of those given by Paull (reference provided in the paper), is also described.

The paper is clearly written, and it presents an interesting application of group theory to the design of routing networks. (A minor comment on presentation: unconventional notations for the empty set and the cardinality of a set are introduced on p. 1627 prior to their definition on the next page.) *S. ★Introduction to linear systems analysis.

John Wiley and Sons, Inc., New York-London, 1962. xi + 403 *pp.* $10.50.

Possibly the only thing that distinguishes this book from many other similar ones on linear system analysis is the inclusion of material on random processes. In Part I, Systems with Explicit Driving Functions, there are ten chapters: (1) Introduction to the Laplace Transform; (2) Translating the Physical Problem into Mathematical Language; (3) More on Laplace Transform Theory; (4) System Concepts; (5) Systems with Feedback; (6) Fourier Transform Analysis; (7) Some General Properties of Physically Realizable Transfer Functions; (8) Distributed-Parameter Systems; (9) Systems with Time-Varying Parameters; (10) The z-Transform. In Part II, Systems with Random Driving Functions, there are five chapters: (11) Essential Notions of Probability; (12) Mathematical Description of a Random Process; (13) The Analysis Problem; (14) Optimization; (15) Further Topics on Optimization. There are two Appendices: (A) Tables of Laplace Transforms; (B) Calculus of Variations and Lagrange's Equations.

The material presented is straightforward and uninspiring, as are the problems at the end of each chapter, and a bit behind the times for the advanced undergraduate or beginning graduate student for whom it is intended.

N. H. Choksy (Silver Spring, Md.)

Doležal, Václav 6988

★Dynamics of linear systems.

Publishing House of the Czechoslovak Academy of Sciences, Prague, 1964. 224 *pp.* *Kčs.* 26.00.

In der Netzwerktheorie treten gewisse Schwierigkeiten auf, die von den Elektrotechnikern meist entweder nicht aufgeklärt oder mit illegitimen Mitteln behandelt werden: Die äußeren Erregungen können Sprünge haben, sind also nicht durchweg differenzierbar, oder sie stellen Impulse

dar, die nicht mit dem Funktionsbegriff erfaßbar sind; die nach den üblichen Methoden hergestellten Lösungen haben andere als die vorgeschriebenen und bei der Herleitung benutzten Anfangswerte. Der Autor stellt sich die Aufgabe, unter Benutzung der Distributionen eine so allgemeine Theorie zu entwickeln, daß solche Widersprüche nicht auftreten und auch die allgemeinsten Erregungen zulässig werden. Das Gleichungssystem der Netzwerktheorie wird in Matrixform geschrieben: (1) $Ax'+Bx+C\int_0^t x(\tau)d\tau=f(t)$ mit den $r\times r$ Matrizen A, B, C und den r-dimensionalen Vektorfunktionen $x(t)$, $f(t)$. Als Anfangsbedingung wird der r-dimensionale konstante Vektor c vorgeschrieben. Das 1. Kapitel verbleibt noch im Rahmen der klassischen Theorie (Funktionen) und sucht einige der genannten Schwierigkeiten dadurch zu beheben, daß statt des Systems (1) das von 0 bis t integrierte System betrachtet wird, in das der Anfangsvektor c eingetreten ist. Bei der Lösung vermittels Laplace-Transformation spielt bekanntlich die Matrix $Z^{-1}(p)$, wo $Z(p)$ die Impedanz $Ap+B+Cp^{-1}$ ist, eine wichtige Rolle. Deshalb werden im 2. Kapitel derartige Matrizen auf ihr funktionentheoretisches Verhalten untersucht. Im 3. Kapitel geht der Autor zu seinem eigentlichen Thema, der Behandlung des Systems (1) im Rahmen der Distributionstheorie, über. Dazu werden zunächst die grundlegenden Eigenschaften der Distributionen aus dem Raum D im Sinne von L. Schwartz entwickelt und aus D die Unterklasse D_L von Distributionen abgegrenzt, die Laplace-Transformierte besitzen. Wenn f ein Vektor über D_L ist, so wird der Vektor x über D_L die Distributionslösung des Systems (1) mit der Anfangsbedingung c genannt, wenn x das System $Ax'+Bx+Cx^{(-1)}=f+Ac\delta_0$ befriedigt. (Das Integral $x^{(-1)}$ wird vorher in geeigneter Weise definiert.) Damit wird den in $t=0$ eventuell auftretenden Sprüngen zwischen gegebenen und angenommenen Anfangswerten Rechnung getragen. Das so formulierte Problem hat immer eine Lösung, von der gezeigt wird, daß sie ein zutreffendes Bild der physikalischen Wirklichkeit liefert. Im 4. Kapitel wird an Stelle von (1) das Differentialgleichungssystem $Ax''+Bx'+Cx=f$ auf der vollen Achse $-\infty<t<\infty$ ohne Transformationstheorie mit Distributionen behandelt, die zu diesem Zweck zu komplexwertigen verallgemeinert werden. Im 5. Kapitel wird das System mit zeitvariablen Koeffizienten

$$(2)\quad \sum_{k=1}^{r}\sum_{m=0}^{n} a_{ikm}(t)x_k^{(m)}(t) + \sum_{k=1}^{r}\int_0^t W_{ik}(t,\tau)x_k(\tau)\,d\tau = f_i(t) \quad (i=1,2,\cdots,r)$$

nach einer Operatorenmethode gelöst, die vom Heaviside-Kalkül inspiriert ist. Nach eingehendem Studium des Produktes $[Wx]$ einer Funktion $W(t,\tau)$ von zwei Variablen mit einer Distribution x von endlicher Ordnung wird die Menge $\mathfrak{A}_n$ der Operatoren $Ax=[Wx]^{(k)}$ betrachtet. Der in (2) vorkommende Operator $Ax=a_mx^{(m)}+\cdots+a_1x'+a_0x+[Wx]$ gehört zu $\mathfrak{A}_n$. Die Lösung von (2) besteht in dem Nachweis der Existenz des inversen Operators A^{-1}. Im 6. Kapitel werden die Eigenschaften von Multipolen, die sonst nur für Systeme mit konstanten elektrischen Elementen (Widerstand, usw.) formuliert werden, auf allgemeine lineare Systeme übertragen, deren Elemente zeitvariabel sein können.

Das Referat kann nur einen kleinen Teil von dem reichen Inhalt des Buches wiedergeben, das einige bisher unbefriedigend behandelte Teile der theoretischen Elektrotechnik auf eine der modernen Analysis entsprechende Basis stellt. *G. Doetsch* (Freiburg)

Naslin, P. 6989

★**Les régimes variables dans les systèmes linéaires et non linéaires.**

Dunod, Paris, 1962. xvi+524 *pp*. 88 *NF*.

Essentially this is a standard book on linear and nonlinear systems of which many have appeared both in English and in French. It differs from most English books in the prolific use of illustrative diagrams, a typical French textbook characteristic. In an introduction of six pages the author lists the general properties of linear and nonlinear systems and the methods of studying them.

Part I, Linear Systems, contains seven chapters. Chapter 1 introduces the p $(=d/dt)$ operator and block diagrams. The author carefully justifies his use of this p operator instead of the more usual complex variable s of the Laplace transform. Electric and mechanical systems are discussed, as are electromechanical analogues. Linearized nonlinear systems are presented. Signal flow graphs are also dealt with in this chapter. Chapter 2 is a standard exposition of the symbolic calculus. Chapter 3 introduces the E operator defined as the delay operator, $Ef(t)=f(t-T)$, which forms the basis of a numerical calculus. Chapter 4 takes up the question of harmonic modes. Chapter 5 discusses the relationship between the transient response and the frequency response. Chapter 6 presents the standard Nyquist and Hurwitz stability criteria, and a new damping criterion based on a new form of the characteristic polynomial. Chapter 7 deals with sampled-data systems with finite pulse-width sampling. Use is made here of the E-transform developed in Chapter 3. There are several places here that a factor of τ, the pulse-width, is omitted from various formulas—notably in equations (7.8), (7.9) and (7.10), and in the seventh, eighth, ninth and tenth rows of the last column of Table 7.2 on page 281.

Part II: Nonlinear Systems, contains three chapters. Chapter 8 extensively discusses various aspects of nonlinear filters. Topological (phase-space) methods are taken up in Chapter 9. The last chapter presents numerical and graphical methods of computing the transient modes of nonlinear systems.

Appendix A presents the Graeffe method for finding the roots of a polynomial equation. Appendix B treats the Fourier series and integral and their use in harmonic analysis. Appendix C is a good discussion of the Laplace transform. *N. H. Choksy* (Silver Spring, Md.)

Brayton, R. K.; Moser, J. K. 6990

A theory of nonlinear networks. I.

Quart. Appl. Math. **22** (1964), 1–33.

This paper is a new and systematic approach to the study of nonlinear RLC-networks. A network here is an idealised concept defined as a set of nodes and a set of connecting branches; it is also called a graph. The entire report is based on the fact that the system of differential equations for such networks has the form: (1) $L_\rho(di_\rho/dt)=\partial P/\partial i_\rho$, $C_\sigma(dv_\sigma/dt)=-\partial P/\partial v_\sigma$ $(\rho=1,\cdots,r,\quad \sigma=r+1,\cdots,r+s)$, where $P=P(i,v)$ is a function describing the physical properties of the resistive part of the network. Since P has the dimension of voltage times current, it is called a mixed potential function. System (1) seems to form a Hamiltonian system but is not so, since, in distinction to the

latter, it contains dissipative terms. The main difference between linear networks and the networks considered here is that in the latter the voltage-current relations for the resistors may be nonmonotonic, i.e., "negative resistances" may occur. Of course, any or all of the elements may be nonlinear.

The mixed potential function $P(i, v)$ is used to construct Ljapunov-type functions for stability considerations. A procedure for obtaining $P(i, v)$ directly from the network is given. The concepts of a complete set of mixed variables and of a complete circuit are introduced. One of the main purposes of the paper is to draw conclusions on the solutions of system (1) from a consideration of its special forms. System (1) preserves its form under coordinate transformations which leave invariant the indefinite metric: (2) $-\sum_{\rho=1}^{r} L_\rho(di_\rho)^2+\sum_{\sigma=r+1}^{r+s} C_\sigma(dv_\sigma)^2$. Special forms of the network, and thus of system (1), occur, for example, if only resistors are present (R-network) or if inductors are absent (RC-network). For such special forms the metric also takes special forms which are studied.

In general, RLC-networks will admit oscillations even in the linear case. The paper derives criteria which rule out self-sustained oscillations in general nonlinear RLC-networks with time-invariant elements.

The set of variables $i_1, \cdots, i_r, v_{r+1}, \cdots, v_{r+s}$ is said to be complete if they can be chosen independently without a violation of Kirchhoff's laws and if they determine in each branch at least one of the two variables, the current or the voltage. The problem is then to determine a complete set of variables for a given graph. The authors show how to solve this problem in several ways, from the voltages and link currents of a maximal tree; a maximal tree is a subgraph not containing any loops and not capable of being enlarged as a tree, and links are branches not contained in the maximal tree. A circuit with a complete set of variables is said to be complete.

Part I ends with an example of an arbitrarily large ladder network containing nonlinear elements. Part I contains the main results without details of proofs and refinements. Part II [#6991 below] complements Part I with detailed proofs and with several additional results.

N. H. Choksy (Silver Spring, Md.)

Brayton, R. K.; Moser, J. K. 6991

A theory of nonlinear networks. II.

Quart. Appl. Math. **22** (1964), 81–104.

Part II recapitulates the results of Part I [#6990 above] and gives details of the proofs of the results cited there. In addition, certain well-known results of electrical network analysis, such as the Foster reactance theorem, are discussed and rederived from the point of view of the existence of a mixed potential function. In the last section a theorem is proved on the existence of periodic solutions for periodically excited nonlinear circuits, which can be considered as an extension of a theorem of R. J. Duffin [Bull. Amer. Math. Soc. **54** (1948), 119–127; MR **9**, 503].

Theorems on the representation of events in Moore-automata.

Ann. Univ. Turku. Ser. A I No. 69 (1964), 14 *pp.*

Bekanntlich (vgl. z.B. V. M. Gluškov [Uspehi Mat. Nauk **16** (1961), no. 5 (101), 3–62; MR **25** #1976]) läßt sich jedes reguläre Ereignis E über einem endlichen Alphabet X in einem passenden endlichen initialen Moore-Automaten mit dem Eingabealphabet X durch eine geeignete Teilmenge S dessen Zustandsmenge A in dem Sinne repräsentieren, daß E aus genau den Wörtern über X besteht, die den Automaten aus seinem Anfangszustand in einen Zustand der Menge S überführen. In der vorliegenden Arbeit werden zunächst für den Fall eines einelementigen Alphabets $X=\{x\}$ Formeln für die minimalen Anzahlen $N_S(E)$ und $N_A(E)$ der Mengen S bzw. A abgeleitet, die für die Repräsentierung eines gegebenen regulären Ereignisses E über $\{x\}$ erforderlich sind. Es wird dazu für die regulären Ereignisse über $\{x\}$ eine Darstellung durch eine eindeutig bestimmte Normalform angegeben, aus der sich die Anzahlen $N_S(E)$ und $N_A(E)$ ablesen lassen. Es wird ferner auch für die regulären Ereignisse über einem beliebigen Alphabet X eine gewisse Art von "Normaldarstellung" hergeleitet (allgemeiner auch für die Ereignisse E, für die $N_S(E)=1$ ist). Sodann werden hinreichende Bedingungen dafür angegeben, daß für ein reguläres Ereignis E über einem beliebigen Alphabet X, bei gegebenem k, $N_S(E)>k$ gilt, und die eine Verallgemeinerung eines von Bodnarčuk [Ukrain. Mat. Ž. **14** (1962), 190–191] für den Fall $k=1$ bewiesenen Resultats sind. Schließlich wird bewiesen, daß ein nichtleeres endliches Ereignis E über einem Alphabet X dann und nur dann irreduzibel ist, d.h. $N_S(E)=|E|$ gilt, wenn E von der Form $E=P_1 \vee P_1P_2 \vee \cdots \vee P_1P_2\cdots P_k$ ist, wobei $P_2, \cdots, P_k$ nichtleere Wörter über X sind.

G. Asser (Greifswald)

Thiele, Helmut 6995

"Klassische" und "moderne" Algorithmenbegriffe.

Mathematische und physikalisch-technische Probleme der Kybernetik, *pp.* 111–146. *Akademie-Verlag, Berlin,* 1963.

Es wird ein allgemeiner Überblick über die bisher entwickelten und verwendeten "klassischen" Algorithmenbegriffe gegeben sowie über die modernen Untersuchungen zur Theorie der algorithmischen Sprachen berichtet. Der Arbeit ist ein umfangreiches Literaturverzeichnis beigefügt. *G. Asser* (Greifswald)

Bloh, A. Š.; Neverov, G. S. 6996

On a method of synthesis of graph-diagrams for algorithms. (Russian)

Dokl. Akad. Nauk BSSR 8 (1964), 568–571.

The authors describe a method by which one can obtain a graph-diagram for certain algorithms which have a specified number of steps and which are originally described by means of characteristic tables. They suggest that the method may be useful in simplifying the programming of certain problems. The method used is similar to a method of Bloh for the synthesis of contact networks [Avtomat. i Telemeh. **22** (1961), 755–764; MR **26** #7473]. *G. N. Raney* (Storrs, Conn.)

Bekišev, G. A. 6997

On the disparallelization of computing algorithms. (Russian)

Vyčisl. Sistemy No. 5 (1962), 22–30.

The author defines for the graph $G=(X,\Gamma)$ an A-partition as an ordered partition (S_α) of X into nonempty subsets such that (for all α) $\Gamma S_\alpha \subset \bigcup_{\beta<\alpha} S_\beta$. The interpretation is that the set X is a collection of operations and that $y\Gamma x$ means that the result of the operation x serves as an argument for the operation y. The results deal with the existence of A-partitions of graphs and estimates of minimal length algorithms corresponding to these. *R. M. Baer* (Berkeley, Calif.)

Moisil, Gr. C. 6998

Entwicklungsstand und Perspektiven der Theorie der konkreten und der abstrakten endlichen Automaten.

Mathematische und physikalisch-technische Probleme der Kybernetik, pp. 454–472. *Akademie-Verlag, Berlin*, 1963.

Es werden Möglichkeiten dargelegt, die abstrakte Automatentheorie auf konkrete Automaten (Schaltungen mit realen Schaltelementen) anzuwenden. Anhand einer Vielzahl von Beispielen wird gezeigt, wie sich die reale Arbeitsweise der verschiedensten Arten von Schaltelementen und damit auch von komplizierten Schaltungen aus solchen Elementen durch kanonische Gleichungen beschreiben lassen, wenn man passende Hilfsvariablen einführt. Damit wird es möglich, die für die Analyse von endlichen abstrakten Automaten entwickelten Methoden unmittelbar zur Analyse von konkreten Automaten zu verwenden. (Bei dem wesentlich wichtigeren Problem der Synthese ist entsprechendes nicht möglich.) Ein umfangreiches Literaturverzeichnis gibt insbesondere einen Überblick über die in Rumänien durchgeführten Arbeiten zu den genannten Fragen. *G. Asser* (Greifswald)

Kálmár, László 6999

Algorithmische Sprachen und Programmierung von Rechenautomaten.

Mathematische und physikalisch-technische Probleme der Kybernetik, pp. 147–176. *Akademie-Verlag, Berlin*, 1963.

Es wird über diejenigen algorithmischen Sprachen (Autokodsprachen) berichtet, zu denen die praktischen Aufgaben der Programmierung von digitalen Rechenautomaten geführt haben. Dabei werden besonders die allgemeinen logischen Prinzipien der Programmierung herausgearbeitet. Grundlage für diese Betrachtungen bildet eine abstrakte Definition der Rechenautomaten die im gewissen Sinne eine "Verfeinerung" des abstrakten Automatenbegriffs von Huffman, Moore, Mealy, Gluškov darstellt, indem nämlich die üblichen Bestimmungsstücke eines abstrakten Automaten zusätzlich so strukturiert werden, wie dies bei realen digitalen Rechenautomaten der Fall ist. Zum Beispiel wird die Menge A der inneren Zustände als Produktmenge der Form $B \times Z^I \times I$ angenommen, wobei B, Z, I gegebene abstrakte Mengen sind. Jeder Zustand ist dann ein Tripel (b, z, i), wobei $b \in B$ den jeweiligen "Betriebszustand" des Rechenautomaten bezeichnet (z.B. Halte- oder Rechenbetrieb), $z \in Z^I$ den Zustand der verschiedenen "Zellen" des Automaten beschreibt (Z ist dabei die Menge der Zustände, die die einzelnen Zellen des Automaten annehmen können während die Menge I als Indexmenge für die verschiedenen Zellen dient, d.h. die Adressen symbolisiert) und $i \in I$ die im "Befehlszähler" eingestellte Adresse angibt. Weitere wichtige Bestimmungsstücke sind die "Eingabefunktion" des Automaten, seine "Adressenzahl", sein "Befehlssystem" und zwei Funktionen zur Dekodierung der Zellenzustände, die sämtlich abstrakt festgelegt werden Dadurch wird es möglich, dem Programmierungsproblem eine ganz abstrakte Fassung zu geben. Der Übergang von einer algorithmischen Sprache zur Programmierungssprache erscheint als ein Übersetzungsproblem, das sich bei bekanntem Übersetzungsalgorithmus unter gewissen Voraussetzungen mittels eines Übersetzungsprogramms (programmierenden Programms) realisieren läßt. Es wird in diesem Zusammenhang die Überzeugung dargelegt, daß die Frage der Existenz einer optimalen algorithmischen Sprache (nach Präzisierung der Gesichtspunkte der Optimalisierung) ein Problem ist, das nur durch eine wissenschaftliche Untersuchung in befriedigender Weise gelöst werden kann. Abschließend werden die Möglichkeiten diskutiert, mit Rechenautomaten auch nichtnumerische Probleme zu lösen. *G. Asser* (Greifswald)

Petrone, Luigi 7000

Linguaggi algoritmici.

Univ. e Politec. Torino Rend. Sem. Mat. **22** (1962/63), 55–77 (1964).

This is a survey article on some concepts and results that arise from the study of the interconnections between grammars of formal languages and types of automata that serve as generating or as recognition devices for various such languages. The paper reports, in particular, on the results concerning regular and context-free languages. *E. Engeler* (Minneapolis, Minn.)

Editorial Office

Mathematical Reviews, University of Michigan, Ann Arbor, Michigan 48103, U.S.A.

Subscription: Price $50 per volume. There will be two volumes in 1965. Checks should be made payable to the American Mathematical Society. Subscriptions should be addressed to the American Mathematical Society, P.O. Box 6248, Providence, R.I. 02904, U.S.A.

The preparation of the reviews appearing in this publication is made possible by support provided by a grant from The National Science Foundation. The publication was initiated with funds granted by the Carnegie Corporation of New York, the Rockefeller Foundation, and the American Philosophical Society held at Philadelphia for Promoting Useful Knowledge. These organizations are not, however, the authors, owners, publishers or proprietors of the publication, and are not to be understood as approving by virtue of their grants any of the statements made or views expressed therein. The comments and opinions expressed in reviews of books and other publications are those of the individual reviewers and do not necessarily represent the views of the Editors or the American Mathematical Society.

Mathematical Reviews will be published in two volumes in 1965; each volume will consist of six monthly issues, and a separate index issue will be published for each volume. Reviews and pages are numbered consecutively.

Journal references in Mathematical Reviews are given in the following form: *Rückschritte der Math.* (6) **5** (**56**) (1960/61), no. 2, 18–53 (1962), where, after the abbreviated title, one has: (series number) volume number (volume number in first series, if given) (nominal date), issue number if necessary, first page—last page (imprint date). If only one date is given, this will usually be interpreted as the nominal date and will be printed immediately after the volume number. If no volume number is given, the year will be used in its place. The symbol ★ precedes the title of a book or other non-periodical which is being reviewed as a whole.

References to reviews in Mathematical Reviews before Volume 20 (1959) are by volume and page number, e.g., MR 15, 122; from Volume 20 on, by volume and review number, e.g., MR **20** #4387 or MR **23** #A123. Reviews reprinted from Applied Mechanics Reviews, Computing Reviews, Mathematics of Computation, Operations Research, Referativnyĭ Žurnal Matematika (Mehanika, etc.), Science Abstracts, or Zentralblatt für Mathematik are identified in parentheses following the reviewer's name by AMR, CR, MC, OR, RŽMat (RŽMeh, etc.), SA, Zbl, respectively.

Printed in Great Britain by William Clowes and Sons, Limited, London and Beccles

TABLE OF CONTENTS FOR VOLUME 29

Mathematical Reviews

Vol. 29, Index 1965 pp. 1309–1438

AUTHOR INDEX

References are to review numbers; an Errata section may be found at the end of this Index. Collections of papers for which an editor (or editors) is named and which are reviewed as a whole are usually listed under the editor's name; e.g., Vais, G. (Editor). Russian authors are listed under the transliterated spelling of Russian used by Mathematical Reviews (see table at the end of this issue). Surnames consisting of more than one part (e.g., van der Corput, de Alfaro, etc.) are listed under the first capital letter.

A few items without personal authors are listed separately at the end of this Index. A star (★) before a title indicates that the item is a book, while a dagger (†) indicates that reference is made to the item in the Errata section at the end of the Index.

KEY INDEX

SUBJECT CLASSIFICATION

This is a list of headings, with code numbers, under which articles were classified during 1965. The headings in capital letters are essentially identical with those appearing in the 1965 monthly issues.

00. GENERAL
- 00 General mathematics
- 04 Collections of papers
- 20 Bibliographies
- 30 Dictionaries and other reference works
- 40 Reports of meetings
- 50 Methodology and philosophy of mathematics
  Philosophy of science, general

01. HISTORY AND BIOGRAPHY
- 05 Ancient
- 10 India, Far East, Maya, etc.
- 15 Medieval and Renaissance
- 20 17th century
- 25 18th century
- 30 19th century
- 35 20th century
- 40 Contemporary
- 50 Biographies, obituaries, personalia
- 60 Collected or selected works; reprintings or translations of classics
- 70 Source books

02. LOGIC AND FOUNDATIONS
- 15 Formalizing verbal reasoning
- 20 Syntax, semantics, deducibility
- 30 Propositional calculus: two-valued
- 32 Logical calculus: first-order, two-valued (functional calculus)
- 40 Logistic, axiomatic set theory, paradoxes
- 50 Many-valued logic, modal logic
- 60 Recursive function theory, Turing computability
- 70 Intuitionism
- 75 Axioms for mathematical systems
- 80 Metatheorems for mathematical systems
- 90 Undecidability, unsolvability in mathematical systems
- 95 Abstract automata theory (see also 94.90)

04. SET THEORY
- 15 Point sets
- 20 Relations
- 30 Transfinite numbers
- 35 Problem of the continuum
- 60 Combinatorial (partitions, etc.)

05. COMBINATORIAL ANALYSIS
- 10 Partitioning, subsets, etc.
- 20 Matrices, magic squares, block designs, configurations
- 30 Factorials, binomial coefficients, polynomials, power series
- 40 Graphs
- 50 Enumeration of graphs

06. ORDER, LATTICES
- 10 Total order
- 20 Partial order
- 30 Lattices
- 40 Modular lattices, continuous geometries
- 50 Distributive lattices
- 60 Boolean algebras and rings
- 70 Boolean algebras with operators

08. GENERAL MATHEMATICAL SYSTEMS

10. THEORY OF NUMBERS
- 005 Tables
- 01 Elementary
- 05 Power residues and reciprocity laws, primitive roots, indices; general binomial congruences
- 10 Diophantine equations
- 20 Diophantine approximation
- 25 Continued fractions and other expansions
- 28 Irrationality, transcendence
- 30 Forms
- 40 Geometry of numbers
- 50 Exponential and power sums
- 54 Turán's method
- 55 Modular and automorphic functions, forms, and groups
- 60 Multiplicative asymptotic theory
- 62 Zeta-function and other Dirichlet series
- 64 Character sums, asymptotic theory
- 65 Distribution of primes
- 70 Additive asymptotic theory
- 75 Sequences of integers (additive bases, density theorems, etc.)
- 80 Probabilistic number theory
- 83 Distribution mod 1
- 85 Arithmetic of hypercomplex numbers
- 90 Algebraic number theory
- 95 Class field theory
- 96 Algebraic function fields
- 97 p-adic fields
- 98 Finite fields

12. FIELDS AND POLYNOMIALS
- 20 Finite fields
- 30 Polynomials
- 40 Galois theory
- 50 Algebraic number fields
- 60 Algebraic function fields
- 70 Valuations, topological fields
- 80 Differential and difference algebra

14. ABSTRACT ALGEBRAIC GEOMETRY (for classical algebraic geometry, see 50.00)
- 10 Theories of equivalence
- 15 Transformations and correspondences
- 20 Curves
- 35 Algebraic properties of function fields
- 40 Arithmetical properties of varieties
- 45 Algebraic geometry over special fields or over rings; rationality questions
- 50 Group varieties, abstract analytic groups
- 52 Abstract derivations and differentials
- 55 Sheaf-theoretic and homological methods
- 60 Birational invariants, genera, etc.

15. LINEAR ALGEBRA
- 05 Vector spaces
- 15 Linear inequalities
- 20 Inequalities involving eigenvalues and eigenvectors
- 25 Miscellaneous inequalities involving matrices
- 30 Eigenvalues and eigenvectors
- 33 Canonical forms, reductions
- 34 Linear sets of linear transformations
- 35 Matrix equations and identities
- 39 Invariants

40 Multilinear algebra
48 Determinants
49 Permanents
80 Linear equations, matrix inversion

16. ASSOCIATIVE RINGS AND ALGEBRAS
10 Ideal theory
15 Commutative ideal theory
20 General commutative theory
24 Polynomials
26 Formal power series
28 Local rings
30 Division rings, simple rings and algebras
35 Structure of rings
40 Radical theory
45 Rings with chain condition
50 Linear representations of rings and algebras (including orders)
60 Modules
70 Galois theory
80 Ordered rings
90 Topological rings
95 Semi-rings, etc.

17. NON-ASSOCIATIVE RINGS AND ALGEBRAS

18. HOMOLOGICAL ALGEBRA

20. GROUP THEORY AND GENERALIZATIONS
10 Free groups, relations
14 General products of groups
16 Group extensions
20 Permutation groups
25 Finite groups (including finite abelian)
28 Burnside problem, conditions for finiteness
30 Abelian groups, general theory
40 Nilpotent, solvable, p-groups
45 Groups with local properties
50 Lattices of subgroups
55 Special subgroups
60 Crystallographic and discrete geometric groups
65 Modular groups, discrete subgroups of classical groups
70 Classical groups
75 Linear groups, general
80 Representations, characters, group algebras
85 Representations of symmetric groups
88 Automorphisms and endomorphisms, groups with operators
90 Ordered groups, ordered semigroups
92 Semigroups
94 Groupoids
96 Quasigroups
98 Loops

22. TOPOLOGICAL GROUPS AND LIE THEORY
10 Topological groups
12 Haar measures
15 Topological algebras
40 Transformation groups
50 Lie groups
55 Classical groups
60 Representations and analysis
70 Homogeneous spaces (topology, differential geometry)
80 Lie algebras
90 Abstract Lie theory
95 Infinite Lie groups
99 Lie theory of differential equations

26. FUNCTIONS OF REAL VARIABLES
10 Foundations: limits and generalizations [elementary topology of the line (or plane) if used for real variables]
20 Calculus: elementary, advanced, etc.
21 Elementary functions
30 Continuity and related questions (modulus of continuity [if not used in boundary behaviour of analytic functions], discontinuities, etc.)
40 Differentiation: general theory
41 Non-differentiability (non-differentiable functions, points of non-differentiability), discontinuous derivatives
42 Generalized derivatives, derivatives of fractional order
47 Mean-value theorems
50 Monotonic functions, general
51 Functions of bounded variation; absolute continuity
52 Convexity; generalizations
53 Generalized monotonic functions
55 Several variables, implicit function theorems, Jacobians. Transformations with several variables
56 Length, area, volume
60 Polynomials
70 Inequalities (of a general and miscellaneous character)
80 Real-analytic functions
81 Quasi-analytic classes of real functions, functions of class C^{∞}
85 Superposition of functions

28. MEASURE AND INTEGRATION
10 Measurable sets, general: Borel fields, non-measurable sets
12 Analytic and Suslin sets
13 Finitely additive set functions, measures; generalizations
15 Special and generalized measures, Carathéodory theory of measure
17 Transfinite diameter and capacity. Hausdorff measures and capacities
20 Measurable and non-measurable functions
25 Integration, general
26 Riemann integral, Lebesgue integral, Denjoy integral, etc.
30 Measure-preserving transformations
31 Invariant measures
32 Ergodic theorems
33 Dynamical systems
40 Length, area, volume
41 Other geometric measure theory

30. FUNCTIONS OF A COMPLEX VARIABLE
01 General questions, foundations
02 Monogenic properties of complex functions (also polygenic and areolar monogenic functions)
09 Inequalities in the complex domain
10 Polynomials
11 Zeros of polynomials
20 Power series
21 Behavior on the boundary of convergence. Overconvergence
24 Dirichlet series
25 Continued fractions
28 Analytic continuation
30 Sequences and series of analytic functions; uniform convergence, normal families, normal functions
35 Integration; integral representations; Cauchy integral, Poisson and Poisson-Stieltjes integrals
38 Moment problems; interpolation problem
40 Conformal mapping, general theory
41 Capacity, harmonic measure
42 Univalent and p-valent functions
43 Coefficient problems
45 Riemann surfaces, uniformization
46 Algebraic functions, Abelian integrals
47 Quasiconformal mapping
49 Automorphic functions and modular functions
50 Maximum principle. Schwarz's lemma, Phragmén-Lindelöf theorems
52 Extremal problems in complex domain
55 Entire functions
60 Meromorphic functions, general theory

61 Distribution of values, Picard-type theorems, Nevanlinna theory, defect (deficiency) theory
62 Theory of cluster sets, prime ends, boundary behavior
65 Bounded functions, positive real part, Blaschke products
66 Bounded mean modulus, bounded characteristic
67 H_p classes and other restrictions
70 Approximation by polynomials and rational functions, Faber polynomials
75 Boundary-value problems, Dirichlet problem
77 Special boundary-value problems; Riemann-Hilbert problem. Inverse boundary problems
79 Algebroidal functions
80 Topological function theory, functions topologically equivalent to analytic mappings
81 Generalized analytic mappings. Pseudo-analytic functions of Bers, Vekua, etc.
82 Functions of hypercomplex variables and generalized variables
85 Spaces of analytic functions
86 Kernel function and applications
87 Algebras of analytic functions

31. POTENTIAL THEORY
10 Harmonic functions in the plane
11 Harmonic functions, general
15 Subharmonic, superharmonic functions
20 Boundary-value problems, Dirichlet problem
21 Capacity and harmonic measure
22 Generalized capacity and potential
30 Biharmonic and polyharmonic functions and equations
35 Poisson's equation

32. SEVERAL COMPLEX VARIABLES
02 Foundations, general questions
10 Multiple power series, formal theory
15 Analytic and meromorphic curves
20 Holomorphic mappings, domains of holomorphy, analytic spaces (see also 57.00)
25 Automorphic functions
30 Approximation theorems

33. SPECIAL FUNCTIONS
04 Number-theoretic functions, special sequences
05 Tables of special functions
10 Exponential and trigonometric functions
15 Gamma and Beta functions
17 Error function, probability integral
19 Elliptic functions and integrals
20 Hypergeometric functions
21 E-functions
25 Cylindrical functions; Bessel functions
27 Spherical functions; Legendre polynomials and functions, spherical harmonics, ultraspherical polynomials
28 Lamé, Mathieu, spheroidal wave functions
29 Wave functions
32 Gegenbauer functions
40 Orthogonal polynomials, general (Chebyshev, Hermite, Jacobi, Laguerre polynomials and functions)

34. ORDINARY DIFFERENTIAL EQUATIONS
02 Solutions in closed form; integration by quadratures; reduction of differential equations
03 Operational calculus
04 General existence and uniqueness theorems, Picard approximations and generalizations
07 Continuous dependence of solution on parameter
10 Analytic theory
20 Linear equations and systems, general coefficients
21 Linear equations with constant coefficients
22 Linear equations with periodic and almost periodic coefficients
30 Boundary-value problems, linear equations
31 Sturm-Liouville theory
32 Eigenvalues, eigenfunctions
33 Eigenfunction expansions
34 Asymptotic properties of eigenfunctions
36 Boundary-value problems, non-linear
40 Qualitative theory of first- and second-order equations and systems; singular points and limit cycles
41 Periodic and almost periodic solutions
42 Non-linear oscillations
43 Stability of first- and second-order equations and systems
50 Qualitative theory of equations and systems of order greater than 2; asymptotic behavior of solutions
51 Stability; periodic and almost periodic solutions
53 Perturbations
54 Singular perturbations; small parameter with highest derivative
60 Stochastic differential equations
65 Dynamical systems, systems on manifolds
70 Equations and systems of infinite order
75 Difference-differential equations
76 Solution by finite differences
80 Differential equations in Banach and other spaces
85 Optimal control problems

35. PARTIAL DIFFERENTIAL EQUATIONS
05 General properties of solutions, Cauchy-Kowalewski theorems, etc.
10 First-order equations and systems
12 Classification of equations and systems
13 Exact equations and integrable systems. Pfaffian equations
15 Characteristics
20 Separation of variables, elementary properties of the equations of mathematical physics
30 Elliptic equations and systems of first and second order
31 Strongly elliptic systems
32 Quasi-linear elliptic equations and systems
33 Schrödinger equation, wave equation
34 Maxwell's equations, Helmholtz equation
35 Spectral analysis, eigenfunctions, operators
36 Elliptic systems and equations of higher order
37 Biharmonic equation
40 Hyperbolic equations and systems of second order
41 Quasi-linear hyperbolic systems and equations of second order
45 Hyperbolic equations and systems of higher order
Parabolic equations of second order
55 Equations of mixed type and second order
Mixed type, order higher than two
Non-linear equations and systems
62 Approximation of solutions
Solution by finite differences
65 Special equations: Navier-Stokes, etc.
70 Asymptotic properties
75 Infinite systems, equations of infinite order
Equations in Banach spaces and other spaces

39. FINITE DIFFERENCES AND FUNCTIONAL EQUATIONS
10 Finite differences, general
12 Solution of ordinary differential equations by finite differences
13 Solution of partial differential equations by finite differences
20 Difference equations
30 Functional equations

40. SEQUENCES, SERIES, SUMMABILITY
10 Series and sequences of numbers, general
11 Infinite products
12 Continued fractions
13 Convergence
15 Multiple series and sequences
20 Sequences and series of functions, convergence
30 Summability, general methods
31 Summability, matrix methods
32 Cesàro summability

30 Abel, Poisson summability
35 Summability of double series
40 Convergence and summability of integrals
42 Tauberian theorems

41. APPROXIMATIONS AND EXPANSIONS
10 Interpolation
15 Polynomial approximation
17 Approximation by rational functions
30 Approximate quadratures
40 Rate of convergence, degree of approximation, best approximation
41 Constructive theory of functions
45 Approximation by smoothing integrals
50 Asymptotic approximations
55 Other methods of approximation

42. FOURIER ANALYSIS
05 Trigonometric polynomials
06 Best approximation by trigonometric polynomials
08 Trigonometric interpolation
10 Fourier coefficients
11 Convergence of Fourier series
15 Orthogonal functions
16 Expansions in orthogonal functions
17 Completeness of sets of orthogonal functions
18 Completeness, closure, spectral synthesis
20 Summability of Fourier and generalized Fourier expansions
25 Fourier transform
26 Other Fourier-type transforms
27 Trigonometric moment problems
30 Almost periodic functions
35 Positive definite functions
40 Multiple Fourier series and integrals
50 Abstract harmonic analysis

44. INTEGRAL TRANSFORMS, OPERATIONAL CALCULUS
10 Laplace transform
25 Convolution
28 General transforms
30 Special transforms: Legendre, Hilbert, etc.
32 Multiple transforms
40 Operational calculus
42 Operational calculus in several variables
50 Fractional derivatives and integrals
60 Moment problems

45. INTEGRAL EQUATIONS
10 Linear integral equations, general
11 Fredholm equations
12 Eigenvalue problems
13 Volterra equations
15 Singular equations
20 Systems of linear equations
30 Non-linear integral equations
31 Singular non-linear equations
40 Integro-differential equations

46. FUNCTIONAL ANALYSIS
10 Topological linear spaces (including normed spaces and Hilbert spaces)
20 Partially ordered linear spaces
30 Special function spaces
40 Distributions
50 Single linear operators in linear or partially ordered spaces
60 Groups or semigroups of linear operators, representations of topological groups
65 Rings of operators, group algebras, abstract topological algebras, and their representations
70 Banach algebras of analytic functions
80 Differential and integral operators
90 Applications of functional analysis

49. CALCULUS OF VARIATIONS

50. GEOMETRY
05 Foundations
10 Euclidean
11 Triangles, tetrahedra
12 Circles, spheres
14 Constructions
15 Descriptive geometry
17 Analytic geometry
20 Affine geometry, general
25 Transformations
30 Projective geometry, general
35 Transformations
38 Second-order loci
40 Non-Euclidean geometry (i.e., hyperbolic or elliptic)
45 Minkowski geometry
48 Special geometries
50 Classical algebraic geometry
51 Foundations
52 Transformations
55 Curves
56 Surfaces
57 Abelian varieties, genera, integrals
60 Finite geometries
70 Projective planes
80 Configurations
90 Regular figures, divisions of space
95 Paradoxical decompositions

52. CONVEX SETS AND GEOMETRIC INEQUALITIES
10 Convex polyhedra
25 Convex curves
30 Convex regions
34 Helly-type theorems
40 Extremum problems and geometric inequalities
45 Packing and covering
50 Distance geometries

53. DIFFERENTIAL GEOMETRY
01 Curves and surfaces in Euclidean spaces
04 Minimal surfaces
10 Affine differential geometry
20 Projective differential geometry
25 Conformal differential geometry
30 Non-Euclidean differential geometry
32 Other special differential geometries
35 Vector and tensor analysis
38 Spinor analysis
40 Differentiable manifolds (general theory), e.g., definitions jets, tangent bundles
42 Differential invariants (local theory), geometric objects
45 Differential calculus (global theory); forms, currents, integration, tensor fields, etc.
50 Connections (general theory), including G-structures
55 Affine connections
60 Projective connections
65 Conformal connections
70 Local Riemannian geometry
72 Riemannian manifolds
75 Global surface theory (convex surfaces)
78 Lorentz metrics and generalizations
80 Kählerian connections and generalizations
85 Finsler spaces and generalizations (areal metrics)
90 Integral geometry
99 Other generalizations (G-spaces of Busemann, etc.)

54. GENERAL TOPOLOGY
10 Axiomatics; generalizations of topological spaces
20 General topological spaces
21 Convergence notions

22 Compactness and generalizations
23 Compactifications, other extensions
24 Proximity spaces
25 Uniform spaces
26 Metric spaces, metrizability
27 Dimension theory
28 Mappings
29 Many-valued mappings
30 Continua
35 Topological semigroups, lattices, etc.
40 Topology of E_2, 2-manifolds
50 Topology of E_n, n-manifolds ($n > 2$)
60 Transformation groups
70 Topological dynamics
80 Fixed-point theorems, coincidence theorems, etc.

55. ALGEBRAIC TOPOLOGY
10 Graphs, map-coloring
20 Knots, links
30 Homology and cohomology theory
32 Sheaves
34 Cohomology (and homology) operations, Steenrod algebra
36 Periodic transformations, fixed points, coincidences (Smith theory)
38 Dimension theory
40 Homotopy theory, general
42 Algebra of mappings (including cohomotopy groups)
45 Computation of homotopy groups
50 Fiber spaces
52 Spectral sequences
60 Manifolds
62 Classification
64 Mappings
66 Generalized manifolds, local homology
68 Homotopy manifolds
70 Imbedding, immersion

57. TOPOLOGY AND GEOMETRY OF DIFFERENTIABLE MANIFOLDS
10 Differentiable structures, cobordism
20 Differentiable mappings, imbeddings, immersions, diffeomorphisms
30 Fiber bundles, tangent bundles
32 Characteristic classes
34 Topology of vector and tensor fields
36 Foliations
40 Topology of Lie groups
45 Topology of homogeneous spaces
50 Analysis on differentiable manifolds
60 Complex manifolds (also in several complex variables)
70 Infinite Lie groups, deformations

60. PROBABILITY
05 Foundations
10 Combinatorial probability theory
15 Geometric probability theory
20 Distributions
30 Limit theorems
40 Stochastic processes, general theory
45 Markov processes
48 Branching processes
50 Stationary processes
55 Random walks, Brownian motion
60 Queuing theory, telephone traffic, storage
62 Renewal theory
65 Other special processes
70 Random noise
90 Other applications

62. STATISTICS
05 Elementary descriptive statistics
10 Distributions of statistical functions
20 Estimation theory: parametric case
25 Testing of hypotheses: parametric case
30 Multivariate analysis, regression analysis
35 Order statistics
40 Non-parametric methods
50 Analysis of experiments
55 Design of experiments
60 Decision theory
65 Multistage decision procedures, sequential analysis
70 Statistical engineering, quality control
75 Life testing
80 Sampling surveys
85 Statistical analysis of stochastic processes, time series analysis
90 Applications

65. NUMERICAL METHODS
05 General mathematical methods, iteration, tables
15 Monte Carlo methods
20 Interpolation, smoothing, least squares, curve fitting, approximation of functions
25 Computation of special functions, series, integrals
30 Mathematical programming
35 Linear equations, determinants, matrices
40 Eigenvalues, eigenvectors, Rayleigh-Ritz method
50 Solution of algebraic and transcendental equations and systems
55 Numerical differentiation and integration, mechanical quadrature
60 Ordinary differential equations
65 Partial differential equations
70 Difference and functional equations
75 Integral and integro-differential equations
80 Error analysis
85 Graphical methods, nomography
90 Harmonic analysis and synthesis

68. COMPUTING MACHINES

69. GENERAL APPLIED MATHEMATICS

70. MECHANICS OF PARTICLES AND SYSTEMS
10 Foundations
20 Statics
30 Kinematics, mechanisms, linkages
40 Dynamics
50 Oscillations, stability
55 Non-linear oscillation
60 Exterior ballistics
70 Variable mass, rockets

73. ELASTICITY, PLASTICITY
05 Foundations of mechanics of deformable solids
06 Elasticity: general theorems
07 Finite deformation
10 Plane stress and strain
15 Three-dimensional problems
25 Beams and rods
30 Plates
32 Shells and membranes
35 Anisotropic bodies
37 Dislocation theory
45 Vibrations, structural dynamics
47 Aeroelasticity
50 Stability, buckling, failure
55 Wave propagation, impact
65 Visco-elasticity
70 Plasticity, creep
80 Soil mechanics
90 Thermo-mechanics

76. FLUID MECHANICS, ACOUSTICS
- 05 Foundations
- 10 Incompressible fluids: general theory
- 15 Incompressible fluids with special boundaries
- 17 Airfoil theory
- 20 Free surface flows, water waves, jets, wakes
- 25 Viscous fluids
- 30 Boundary layer theory
- 35 Stability of flow
- 37 Convection
- 40 Turbulence
- 45 Rarefied gas flow
- 50 Compressible fluids: general theory
- 55 Compressible fluids: subsonic flow
- 60 Compressible fluids: transonic flow
- 65 Compressible fluids: supersonic and hypersonic flow
- 70 Shock waves
- 75 Aero- and hydrodynamic sound
- 80 Acoustics
- 85 Non-Newtonian fluids
- 90 Magnetohydro- and aerodynamics, ionized gas flow (see also 78.30 ; 82.25 ; 85.50)
- 92 Quantum hydrodynamics
- 93 Relativistic hydrodynamics
- 95 Diffusion, filtration

78. OPTICS, ELECTROMAGNETIC THEORY, CIRCUITS
- 05 Geometric optics
- 10 Physical optics
- 20 Electron optics
- 30 Space charge waves
- 40 Electromagnetic theory
- 45 Electro- and magnetostatics
- 50 Waves and radiation
- 60 Diffraction, scattering
- 70 Antennas, wave-guides
- 80 Circuits, networks (for switching theory, see 94.70)
- 90 Technical applications

80. CLASSICAL THERMODYNAMICS, HEAT TRANSFER
- 10 Classical thermodynamics
- 20 Heat and mass transfer
- 30 Combustion, interior ballistics
- 40 Chemical kinetics

81. QUANTUM MECHANICS
- 10 General theory
- 15 Scattering theory
- 20 Mathematical field theory
- 22 Dispersion relations
- 24 Weak interactions
- 26 Elementary particles
- 28 Nuclear physics
- 30 Atomic physics
- 38 Molecular physics
- 50 Quantum mechanics of many-body systems
- 60 Superconductivity and superfluidity
- 70 Quantum statistical mechanics

82. STATISTICAL PHYSICS, STRUCTURE OF MATTER
- 05 General statistical mechanics
- 10 Quantum statistical mechanics
- 15 Statistical thermodynamics
- 17 Irreversible thermodynamics
- 20 Kinetic theory of gases
- 25 Plasma (see also 76.90)
- 30 Liquids
- 40 Solids
- 45 Crystals
- 50 Metals
- 60 Transport processes
- 65 Nuclear reactor theory

83. RELATIVITY
- 10 Special relativity
- 20 General relativity
- 30 Unified field theories
- 40 Other relativistic theories

85. ASTRONOMY
- 10 Celestial mechanics
- 15 Galactic and stellar dynamics
- 20 3- and n-body problems
- 27 Astronautics
- 30 Stellar structure
- 40 Stellar atmospheres, radiative transfer
- 50 Hydrodynamic and hydromagnetic problems
- 60 Statistical astronomy
- 70 Cosmology
- 80 Special problems
- 90 Radio astronomy

86. GEOPHYSICS
- 10 Hydrology, hydrography, oceanography
- 20 Meteorology
- 30 Seismology
- 40 Potentials, prospecting
- 50 Geo-electricity and magnetism
- 60 Geodesy, mapping problems
- 70 Atmospheric physics

90. ECONOMICS, OPERATIONS RESEARCH, GAMES
- 05 Decisions, utility
- 10 Economic models
- 15 Economic time-series analysis
- 17 Miscellaneous applications to economics
- 30 Management science, operations research
- 35 Highway traffic
- 40 Actuarial theory
- 50 Linear programming
- 52 Transportation problems
- 54 Flows in networks
- 56 Integer programming
- 58 Non-linear programming
- 60 Logistics, inventory, storage
- 70 Games

92. BIOLOGY AND BEHAVIORAL SCIENCES
- 10 Biology
- 20 Genetics
- 30 Population dynamics, epidemiology
- 40 Sociology
- 50 Psychology
- 55 Nervous networks

94. INFORMATION, COMMUNICATION, CONTROL
- 05 Foundations, coding theorem
- 10 Statistical theory of communication channels, filters
- 13 Detection
- 15 Codes, decoding
- 20 Data processing
- 30 Linguistics, machine translation
- 55 Control systems
- 57 Stability of control systems
- 60 Optimal control
- 65 Random control
- 70 Switching theory, relays
- 80 Servomechanisms
- 90 Automata (see also 02.95)

ABBREVIATIONS OF NAMES OF JOURNALS

This list gives the form of references used in MATHEMATICAL REVIEWS and the complete title; the place of publication and other pertinent information are given in parentheses when desirable for clarity.

Abh. Akad. Wiss. Göttingen Math.-Phys. Kl. Abhandlungen der Akademie der Wissenschaften in Göttingen. Mathematisch-Physikalische Klasse. (Göttingen)

Abh. Deutsch. Akad. Wiss. Berlin Kl. Math. Phys. Tech. Abhandlungen der Deutschen Akademie der Wissenschaften zu Berlin. Klasse für Mathematik, Physik und Technik. (Berlin)

Abh. Dokumentationszentrums Technik Wirtschaft. Abhandlungen des Dokumentationszentrums der Technik und Wirtschaft. (Vienna)

ERRATA AND ADDENDA

VOLUME 22

#2976: Landsberg, Max

In lines 1 and 2, the name "Condry" should be replaced by "Cauchy".

VOLUME 26

#2918: Zylbertrest, S.

In connection with the last sentence of the first paragraph of the review, the reviewer calls attention to a paper of R. Raghavendran [Math. Student **28** (1960), 65–70; MR **26** #2917].

Wightman, A. S.

On p. 1514 of the Index issue the review numbered 1339 should be 7339.

VOLUME 27

#5867: Teleman, Silviu

The reviewer adds the following correction. The algebra $C^*(\Sigma_d)$ is isomorphic (as a Banach algebra) to $C_{rs}(G)$ as discussed, for example, in (19.23.b) of Hewitt and Ross, *Abstract harmonic analysis*, Vol. I: *Structure of topological groups. Integration theory, group representations* [Academic Press, New York, 1963; MR **28** #158]. Thus, contrary to a statement in the review, $C^*(\Sigma_d)$ need not be commutative even if G is [op. cit., (19.24.b)].

Newman, Morris

On p. 1338 of the Index issue, review #2551 should be attributed to Michael F. Newman.

VOLUME 28

#2545: Gray, John W.

The correct bibliographical reference in the heading should be *Topology* **3** (1965), 1–18.

#2554: Raymond, Frank

The correct bibliographical reference in the heading should be *Topology* **3** (1965), 43–57.

#2937: Barbashin, E. A.; Tabueva, V. A.

The reviewer wishes to replace the first sentence of the review by the following. "The system studied in the authors' earlier paper [Avtomat. i Telemeh. **23** (1962), 1290–1297; MR **27** #6649] is again considered; the notation used below will be that of the review [MR **27** #6649] of the earlier paper. Assume that $A = B^2 - aB + b > 0$, $B > 0$."

#4713: Tetere, G. A.

The title of the journal should be completed by *Fiz. Tehn. Zinātņu Sēr.*

#4974: Mucenieks, V. A.; Rastrigin, L. A.

The title of the journal should be completed by *Fiz. Tehn. Zinātņu Sēr.*

#5063: Kolchin, E. R.

The correct bibliographical reference in the heading should be *Topology* **3** (1965), *suppl.* **2**, 309–318.

#5402: Tabata, Morio

The author's name should read Obata, Morio.

Tabata, Morio

On p. 1210 of the Index issue, the author's name should read Obata, Morio.

Volume 29

#196: Kobayashi, Shoshichi; Nagano, Tadashi

In line 3 of the review, replace (1906) by (1909).

#618: Hilton, P. J.

The correct bibliographical reference in the heading should be *Topology* **3** (1965), *suppl.* 2, 161–176.

#656: Georgiou, P.

The reviewer wishes to change "... of B) ..." in line 8 from the bottom of the review to "... of the boundary of B) ...".

#827: Green, A. E.

The reviewer wishes his comment at the end of the review to read as follows. "In the reviewer's opinion, equation (2) above is not at least unjustified. The utility of the author's continuum theory of anisotropic fluids will better wait till some specific problems are solved using that theory. It is too early to decide."

#1229: Taft, Earl J.

The author communicates that, although the hypotheses for the existence result are stated correctly, the hypotheses for the conjugacy result are too stringent; all that one needs is that G be completely reducible and that the characteristic not be 2.

#1248: Mendelsohn, N. S.

The author points out that the proof of Lemma 1 on p. 512 is incorrect, but that it can be rectified. A corrected version will appear in the same journal.

#1581: Coxeter, H. S. M.

In line 4 of the review, the expression $2f_{n-1}(x)/f_n(x)$ should read $2f_{n-1}(n)/f_n(n)$, according to the author.

#2198: Kislicyn, S. S.

The reviewer wishes to replace the last line of the review by the following. "This conjecture was disproved by L. R. Ford, Jr., and S. M. Johnson [Amer. Math. Monthly **66** (1959), 387–389; MR **21** #1942]."

#2463: Kukles, I. S.; Nurov, T.

The second displayed formula should be $\omega_2(x, y) = \frac{1}{2}(x^2+y^2)$ and not $\omega_2(x, y) = \frac{1}{2}(x^2-y^2)$. In addition, a more accurate reference to Ljapunov is the following: *General problem of the stability of motion* (Russian), pp. 206–207, GITTL, Moscow, 1950 [MR **12**, 612].

#2780: Edelstein, Michael

In line 2, replace "$f^m(E^n)$" by "$f^m(A)$, for any bounded $A \subset E^n$,".
